<p>Bakris et al.<sup>135</sup> (2008) GUARD</p> <p>Benazepril and HCTZ (fixed-dose combination)</p> <p>vs</p> <p>amlodipine and benazepril (fixed-dose combination)</p>	<p>DB, RCT</p> <p>Hypertensive, albuminuric type 2 diabetic patients, mean age 58 years were randomized to receive either initial fixed-dose combination product</p>	<p>N=322</p> <p>52 weeks</p>	<p>Primary: Change in urinary albumin to creatinine ratio after 1 year of initial treatment with either fixed-dose combination, blood pressure reductions</p> <p>Secondary: Proportion who progressed to overt diabetic nephropathy, safety</p>	<p>Primary: Both combinations significantly reduced the urinary albumin to creatinine ratio compared to baseline (P&lt;0.0001). The median percent change was -72.1% for benazepril and HCTZ and -40.5% for amlodipine and benazepril (P&lt;0.0001).</p> <p>Both regimens significantly reduced SBP and DBP compared to baseline (P&lt;0.0001). The mean reduction in both SBP and DBP was greater in the amlodipine-based arm than in the HCTZ-based arm; however, significance in favor of the amlodipine regimen was observed only for DBP (SBP, -20.5 vs -18.8; P=0.19; DPB, -13.1 vs -9.97; P=0.02).</p> <p>A greater proportion of patients who had microalbuminuria at baseline and treated with benazepril and HCTZ compared to amlodipine and benazepril attained normalization of the urinary albumin to creatinine ratio, defined as &lt;30 mg/g (69.2 vs 47.8%; P=0.0004).</p> <p>Secondary: The percentage of patients progressing to overt proteinuria was similar for both groups.</p> <p>Overall, both study drugs were well tolerated. Adverse reactions possibly related to the study medications occurred in 11.4 and 3.6% of patients receiving amlodipine and benazepril and benazepril and HCTZ, respectively. They included peripheral edema (7.8 vs 2.4%, respectively), fatigue (1.2% in each group), pitting edema (1.2 vs 0.0%), face edema (0.6 vs 0.0%) and thirst (0.6 vs 0.0%). More patients receiving the HCTZ-based regimen (10.8%) discontinued study drug than with the amlodipine-based regimen due to side effects (5.4%).</p>
<p>Esnault et al.<sup>136</sup> (2008)</p> <p>Enalapril 5 to 20 mg/day</p>	<p>MC, DB, PC, RCT</p> <p>Nondiabetic, adult patients with estimated creatinine</p>	<p>N=263</p> <p>3 years</p>	<p>Primary: Change in GFR measured yearly by blood clearance</p>	<p>Primary: No statistically significant difference was found between amlodipine and enalapril in GFR decline (-4.92 and -3.98 mL/min., respectively, at last observation).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs amlodipine 5 to 10 mg QD	clearance of 20 to 60 ml/min		Secondary: Composite of renal events and tolerability	Secondary: No statistically significant difference was found between amlodipine and enalapril in the composite secondary end point after a median follow-up of 2.9 years, including in the subgroup of patients with proteinuria >1 g/d at baseline.
Barnett et al. <sup>137</sup> (2004) DETAIL Enalapril 20 mg/day vs telmisartan 80 mg/day	DB, MC, PG, RCT  Patients aged 35 to 80 years with type 2 diabetes and HTN	N=250  5 years	Primary: Change in the GFR  Secondary: Annual changes in GFR, serum creatinine level, urinary albumin excretion, and blood pressure; rates of ESRD and cardiovascular events; all-cause mortality	Primary: After five years, GFR decreased by 17.9 mL/minute/1.73 m <sup>2</sup> with telmisartan compared to 14.9 mL/min/1.73 m <sup>2</sup> with enalapril (mean difference, -3.0 mL/min/1.73 m <sup>2</sup> ; 95% CI, -7.6 to 1.6). Therefore, the changes in GFR were comparable between the groups.  Secondary: The effects of the two agents on the secondary end points were not significantly different after five years.
Mogensen et al. <sup>138</sup> (2000) CALM Lisinopril 20 mg QD vs candesartan 16 mg QD vs lisinopril 20 mg QD plus candesartan 16 mg QD	DB, DD, MC, PG, RCT  Patients 30 to 75 years old with HTN, type 2 diabetes, and microalbuminuria	N=199  24 weeks	Primary: Blood pressure and urinary albumin:creatinine ratio  Secondary: Not reported	Primary: At 12 weeks, mean reductions in DBP were 9.7 mm Hg (P<0.001) and 9.5 mm Hg (P<0.001), respectively, and in urinary albumin:creatinine ratio were 46% (P<0.001) and 30% (P<0.001) for lisinopril and candesartan, respectively.  Compared to either agent alone, at 24 weeks the combination of lisinopril plus candesartan resulted in 16.3 mm Hg reduction in mean DBP vs 10.4 mm Hg for candesartan alone (P<0.001) and 10.7 mm Hg for lisinopril alone (P<0.001).  The reduction in urinary albumin:creatinine ratio with combination treatment (50%) was greater than with lisinopril alone (39%; P<0.001) and candesartan alone (24%; P=0.05).  All treatments were generally well tolerated.  Secondary:

			year	
DREAM Trial Investigators <sup>140</sup> (2006) DREAM  Ramipril up to 15 mg/day  vs  placebo	DB, MC, PC, PRO, RCT, 2-by-2 factorial design  Adults aged 30 years or more with impaired fasting glucose and/or impaired glucose tolerance and no previous cardiovascular disease	N=5,269  3 years (median)	Primary: Composite of newly diagnosed diabetes or death  Secondary: Regression to normoglycemia, glucose levels, composite of cardiac and renal events (were not yet analyzed at the time of this publication)	Primary: The composite primary outcome did not differ significantly between the ramipril group (18.1%; HR, 0.91; 95% CI, 0.81 to 1.3; P=0.15) and the placebo group (19.5%).  Secondary: Participants receiving ramipril were more likely to have regression to normoglycemia than those receiving placebo (HR, 1.16; 95% CI, 1.07 to 1.27; P=0.001).  At the end of the study, the median fasting plasma glucose level was not significantly lower in the ramipril group than in the placebo group (P=0.07), though plasma glucose levels two hours after an oral glucose load were significantly lower in the ramipril group (P=0.01).
GISEN Group <sup>141</sup> (1997) REIN  Ramipril 1.25 mg/day  vs  placebo	DB, PC, RCT  Patients between 18 and 70 years who were either normotensive (<140/90 mm Hg) or hypertensive with chronic nephropathy and persistent proteinuria, who had not received ACE inhibition therapy for ≥2 months	N=166  16 months	Primary: Rate of GFR decline, extent to which this effect was dependent on the drug's antiproteinuric effect  Secondary: Blood pressure control, time to doubling of baseline serum creatinine or progression to end-stage renal failure, cardiovascular complications, total and cardiovascular	Primary: Mean rate of GFR decline per month was significantly lower in the ramipril group than in the placebo group (0.53 mL/min vs 0.88 mL/min; P=0.03).  Among the ramipril-assigned patients, percentage reduction in proteinuria was inversely correlated with decline in GFR (P=0.035) and predicted the reduction in risk of doubling of baseline creatinine or end-stage renal failure (18 ramipril vs 40 placebo; P=0.04).  Secondary: Blood pressure control and the overall number of cardiovascular events were similar in the two treatment groups.  Fifty-eight patients (18 in the ramipril group and 40 in the placebo group) reached the combined end point of doubling of baseline serum creatinine concentration or end-stage renal failure (P=0.02). The risk of progression was still significantly reduced after adjustment for changes in SBP (P=0.04) and DBP (P=0.04) with ramipril, but not after adjustment for changes in proteinuria.

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
			mortality	Note: Originally, 352 patients were placed into stratum 1 (urinary protein excretion exceeding 1 g/24 hours) or stratum 2 (urinary protein excretion exceeding 3.0 g/24 hours). At the second planned interim analysis, the difference in decline in GFR between the ramipril and placebo groups in stratum 2 was highly significant (P=0.001). The Independent Adjudicating Panel therefore decided to open the randomization code and do the final analysis in this stratum while stratum 1 continued in the trial.
<p>Uresin et al.<sup>142</sup> (2007)</p> <p>Aliskiren 150 to 300 mg QD</p> <p>vs</p> <p>ramipril 5 to 10 mg QD</p> <p>vs</p> <p>aliskiren 150 to 300 mg and ramipril 5 to 10 mg QD</p>	<p>DB, MC, RCT</p> <p>Patients ≥18 years of age with type 1 or type 2 diabetes mellitus and stage 1 to 2 HTN (mean sitting DBP) &gt;95 and &lt;110 mm Hg)</p>	<p>N=837</p> <p>8 weeks</p>	<p>Primary: Change in mean sitting DBP</p> <p>Secondary: Change in mean sitting SBP, proportion of patients with a successful response to treatment (trough mean sitting DBP &lt;90 mm Hg and/or ≥10 mm Hg reduction from baseline), rates of blood pressure control (blood pressure &lt;130/80 mm Hg), changes from baseline in 24-hour ABPM measurements, and changes in biomarkers (plasma renin concentration, plasma renin</p>	<p>Primary: Aliskiren monotherapy, ramipril monotherapy, and aliskiren and ramipril combination therapy lowered mean sitting DBP by 11.3, 10.7, and 12.8 mm Hg, respectively. Treatment with aliskiren and ramipril combination therapy produced significantly greater reductions from baseline in mean sitting DBP compared to either aliskiren monotherapy (P=0.043) or ramipril monotherapy (P=0.004). Aliskiren 300 mg was statistically non-inferior (P=0.0002) to ramipril 10 mg for the change in mean sitting DBP.</p> <p>Secondary: Aliskiren monotherapy, ramipril monotherapy, and aliskiren and ramipril combination therapy lowered mean sitting SBP by 14.7, 12.0, and 16.6 mm Hg, respectively. Treatment with aliskiren and ramipril combination therapy produced significantly greater reductions from baseline in mean sitting SBP compared to ramipril monotherapy (P&lt;0.0001), but not aliskiren monotherapy (P=0.088). Aliskiren monotherapy was statistically superior to ramipril for the change in mean sitting SBP (P=0.021).</p> <p>The proportion of patients with a successful response to therapy was similar for aliskiren and ramipril combination therapy (74.1%) and aliskiren monotherapy (73.1%). The responder rates in both groups were significantly higher (P&lt;0.05) compared to ramipril monotherapy (65.8%).</p> <p>Rates of blood pressure control with aliskiren and ramipril combination pressure (13.1%) were not significantly different compared to aliskiren monotherapy (8.2%) or ramipril monotherapy (8.4%).</p> <p>All treatments significantly lowered mean 24-hour ambulatory blood pressure. Aliskiren and ramipril combination therapy was significantly more effective compared to ramipril monotherapy in lowering 24-hour</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
			activity, aldosterone)	mean ambulatory DBP (P=0.034). There was no significant difference in 24-hour ambulatory SBP compared to ramipril monotherapy.  Aliskiren significantly reduced plasma renin activity from baseline as monotherapy (by 66%, P<0.0001) or in combination with ramipril (by 48%, P<0.0001).
Agodoa et al. <sup>143</sup> (2001) AASK  Ramipril 2.5 to 10 mg QD  vs  amlodipine 5 to 10 mg QD	DB, MC, RCT  African American patients, age 18 to 70 years old, with hypertensive renal disease (GFR 20 to 65 mL/min)	N=1,094  4 years	Primary: Rate of change in GFR (GFR slope)  Secondary: Composite of: confirmed reduction GFR by 50% or by 25 mL/min for baseline, ESRD	Primary: The average decline in GFR was slower, by 36% in the ramipril group as compared to the amlodipine group (P=0.002). However, during the first three months, GFR increased more in the amlodipine group than the ramipril group (P<0.001). The mean total slope did not differ between the groups (P=0.38).  Secondary: The risk reduction for the composite secondary outcome was significantly greater for the ramipril group than the amlodipine group (P=0.005). The rate of ESRD was significantly lower in the ramipril group (P=0.01).
Wright et al. <sup>144</sup> (2002) AASK  Ramipril 2.5 to 10 mg/day  vs  amlodipine 5 to 10 mg/day  vs  metoprolol 50 to 200 mg/day	DB, MC, RCT  Patients were self-identified African Americans aged 18 to 70 years with HTN and a GFR between 20 and 65 mL/min/ 1.73 m <sup>2</sup> and no other identified cause of renal insufficiency	N=1,094  3-6.4 years	Primary: Rate of change in GFR (grouped by usual blood pressure [MAP goal 102 to 107 mm Hg] vs lower blood pressure [ $\leq$ 92 mm Hg])  Secondary: Clinical composite outcome (reduction in GFR by 50% or more, ESRD, or death)	Primary: No significant difference in primary outcome was reported between the usual blood pressure group compared to the lower blood pressure group (P=0.24).  None of the drug group comparisons showed consistently significant differences in the GFR slope.  Secondary: The lower blood pressure goal did not significantly reduce the rate of the clinical composite outcome (risk reduction for lower blood pressure group, 2%; 95% CI, -22 to 21; P=0.85).  Ramipril resulted in significant risk reductions in the clinical composite outcomes compared to amlodipine (38%; 95% CI, 14 to 56; P=0.004) and metoprolol (22%; 95% CI, 1 to 38; P=0.04).  There was no significant difference in the clinical composite outcome between the amlodipine and metoprolol groups.

There was a nonsignificant trend for reduction in ESRD (P=0.07) and doubling of serum creatinine (P=0.08) with ACE inhibitors compared to placebo or no treatment. ACE inhibitors significantly reduced the risk of progression from microalbuminuria to macroalbuminuria (P=0.0007) and increased regression back to normoalbuminuria (P&lt;0.0001) compared to placebo or no treatment.</p> <p>ARBs did not significantly reduce all-cause mortality compared to placebo or no treatment (RR, 0.99; 95% CI, 0.85 to 1.17; P=0.95). ARBs significantly reduced the risk of ESRD (P=0.001) and doubling of serum creatinine (P=0.004). ARBs significantly decreased the risk of progression to macroalbuminuria (P=0.001) and increased regression to normoalbuminuria (P=0.02) compared to placebo or no treatment.</p> <p>The three trials that compared ACE inhibitors to ARBs did not report on all-cause mortality, ESRD or doubling of serum creatinine. Progression from microalbuminuria to macroalbuminuria was reported in one trial (N=92) and there was no significant difference in risk, with the point estimate favoring ACE inhibitors (RR, 0.16; 95% CI, 0.02 to 1.44). Regression from microalbuminuria to normoalbuminuria in 1 trial showed</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
ARBs				<p>a nonsignificant difference in the risk.</p> <p>Secondary: Not reported</p>
<p>Strippoli et al.<sup>151</sup> (2006)</p> <p>ACE inhibitors vs placebo or ARBs vs placebo or ACE inhibitors vs ARBs</p>	<p>MA</p> <p>Patients with diabetic kidney disease</p>	<p>N=12,067 (49 trials)</p> <p>≥6 months</p>	<p>Primary: All-cause mortality, ESRD, doubling of serum creatinine concentration, progression from micro- to macroalbuminuria, regression from micro- to normoalbuminuria, drug-related toxicity (including cough, headache, hyperkalemia, impotence and pedal edema)</p> <p>Secondary: Not reported</p>	<p>Primary: There was no significant difference in the risk of all-cause mortality for ACE inhibitors vs placebo or no treatment (RR, 0.91; 95% CI, 0.71 to 1.17) and ARBs vs placebo or no treatment (RR, 0.99; 95% CI, 0.85 to 1.17). No statistically significant reduction in the risk of all-cause mortality was found in the three studies that compared ACE inhibitors with ARBs (RR, 0.92; 95% CI, 0.31 to 2.78).</p> <p>A subgroup analysis of studies showed a significant reduction in the risk of all-cause mortality with the use of full-dose ACE inhibitors (RR, 0.78; 95% CI, 0.61 to 0.98) but not when using half or less than half the maximum tolerable dose of ACE inhibitors (RR, 1.18; 95% CI, 0.41 to 3.44).</p> <p>There was a significant reduction in the risk of ESRD with ACE inhibitors and ARBS compared to placebo or no treatment (RR, 0.60; 95% CI, 0.39 to 0.93 and RR, 0.78; 95% CI, 0.67 to 0.91, respectively). There was a significant reduction in the risk of doubling of serum creatinine concentration with ACE inhibitors and ARBS (RR, 0.68; 95% CI, 0.47 to 1.0 and RR, 0.79; 95% CI, 0.67 to 0.93, respectively).</p> <p>ACE inhibitors and ARBS significantly reduced the risk of progression from micro- to macroalbuminuria (RR, 0.45; 95% CI, 0.29 to 0.69 and RR, 0.49; 95% CI, 0.32 to 0.75, respectively). ACE inhibitors and ARBS significantly increased the regression from micro- to normoalbuminuria compared to placebo or no treatment (RR, 3.06; 95% CI, 1.76 to 5.35 and RR, 1.42; 95% CI, 1.15 to 1.93, respectively).</p> <p>The seven studies that compared ACE inhibitors to ARBS did not report the outcome of ESRD or doubling of serum creatinine. Progression from micro- to macroalbuminuria and from micro- to normoalbuminuria were evaluated each in one trial and showed a nonsignificant difference in the risk between ACE inhibitors and ARBS.</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>ACE inhibitors were associated with a significant increase in the risk of cough but not hyperkalemia, headache or impotence when compared to placebo or no treatment. ARBS were associated with a significant increase in the risk of hyperkalemia but not cough or headache compared to placebo or no treatment.</p> <p>Secondary: Not reported</p>
<b>Miscellaneous</b>				
<p>Montalescot et al.<sup>152</sup> (2009) ARCHIPELAGO</p> <p>Enalapril 10 mg QD, followed by 20 mg QD on day 15</p> <p>vs</p> <p>irbesartan 150 mg QD, followed by 300 mg QD on day 15</p>	<p>AC, DB, MC, RCT</p> <p>Adults with non-ST elevation ACS</p>	<p>N=429</p> <p>60 days</p>	<p>Primary: Change from baseline in high-sensitivity C-reactive protein at day 60</p> <p>Secondary: Changes in other inflammatory markers such as troponin I</p>	<p>Primary: High-sensitivity C-reactive protein levels were comparable in both treatment groups (irbesartan: 15.2 mg/L at baseline, 6.5 mg/L at day 60; absolute change of -8.7 mg/L; enalapril: 12.6 mg/L at baseline, 5.5 mg/L at day 60; absolute change of -7.1 mg/L, P value not significant).</p> <p>Secondary: Similarly, mean levels of markers of myocardial injury (troponin I) and endothelial dysfunction (microalbuminuria) also decreased from baseline to day 60, with no significant differences between treatment groups.</p>
<p>Dagenais et al.<sup>153</sup> (2008)</p> <p>Ramipril 15 mg or rosiglitazone 8 mg QD</p> <p>vs</p> <p>placebo</p>	<p>DB, PC, RCT</p> <p>Adults &gt;30 years with impaired fasting glucose or impaired glucose tolerance without known cardiovascular disease or renal insufficiency</p>	<p>N=5,269</p> <p>3 years</p>	<p>Primary: Composite cardiorenal outcome (first occurrence of any cardiovascular death, nonfatal MI, stroke, new heart failure, progression to microalbuminuria</p>	<p>Primary: Compared to placebo, neither ramipril (15.7 vs 16.0%; HR, 0.98; P=0.75) nor rosiglitazone (15.0 vs 16.8%; HR, 0.87; P=0.07) reduced the risk of the cardiorenal composite outcome.</p> <p>Secondary: Ramipril had no impact on the cardiovascular disease and renal components. Rosiglitazone increased heart failure (0.53 vs 0.08%; HR, 7.04; P=0.01), but reduced the risk of the renal component (HR, 0.80; P=0.005).</p>

**Additional Evidence**

Dose Simplification

Taylor et al. evaluated adherence rates with amlodipine and benazepril fixed-dose combination compared to an ACE inhibitor plus a long-acting dihydropyridine administered as separate formulations. There was no significant difference in adherence in younger subjects (18 to 39 year olds); however, in all age group combined, adherence rates were higher with amlodipine and benazepril compared to the use of an ACE inhibitor plus a long-acting dihydropyridine (80.8 vs 73.8%; P<0.001).<sup>156</sup> Dickson et al. evaluated adherence rates with amlodipine and benazepril fixed-dose combination compared to an ACE inhibitor plus a long-acting dihydropyridine administered as separate formulations in an elderly Medicaid population. Over a 12 month period, adherence rates were reported to be significantly higher with fixed-dose combination product compared to the administration of an ACE inhibitor and dihydropyridine as separate formulations (63.4 vs 49.0%; P<0.0001).<sup>157</sup> Dezzi et al. also reported significantly higher compliance rates at 12 months in patients receiving fixed-dose lisinopril and hydrochlorothiazide (68.7%) or enalapril and hydrochlorothiazide (70.0%) vs administration of the components as separate formulations (57.8 and 57.5%, respectively; P<0.05 for both comparisons).<sup>158</sup>

Stable Therapy

Sapienza et al. evaluated the impact of converting long-term care patients from high-dose calcium-channel blockers or ACE inhibitor plus calcium-channel blockers to a fixed-dose combination of amlodipine/benazepril. There was no significant change in blood pressure from baseline following the conversion; however, there was a significant reduction (81.8%) in the number of patients reporting ≥1 drug-related adverse event (22 vs 4; P<0.05), particularly edema (75% reduction).<sup>159</sup>

Impact on Physician Visits

A search of Medline and PubMed did not reveal data pertinent to this topic.

**IX. Cost**

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of '\$' signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 12. Relative Cost of the Angiotensin-Converting Enzyme Inhibitors**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost
<b>Single Entity Agents</b>

Fosinopril and HCTZ	tablet	N/A	N/A	\$\$\$
Lisinopril and HCTZ	tablet	Prinzide®*, Zestoretic®*	\$\$\$\$	\$
Quinapril and HCTZ	tablet	Accuretic®*	\$\$\$\$	\$\$

\*Generic is available in at least one dosage form or strength.  
HCTZ=hydrochlorothiazide, N/A=not available

## X. Conclusions

All of the angiotensin-converting enzyme (ACE) inhibitors are approved for the treatment of hypertension. Some of the products are also approved for the treatment of diabetic nephropathy, heart failure, and post-myocardial infarction.<sup>3-19</sup> The ACE inhibitors are available as single entity products, as well as in combination with hydrochlorothiazide or verapamil. All of the products are available in a generic formulation.

There are numerous national and international guidelines that recommend the use of ACE inhibitors in patients with the following conditions: acute coronary syndrome, cerebrovascular disease, coronary artery disease, diabetes, diabetic nephropathy, heart failure, hypertension, left ventricular dysfunction, left ventricular hypertrophy, previous myocardial infarction, and renal disease. In general, guidelines do not give preference to one ACE inhibitor over another.<sup>20-38</sup> Thiazide-type diuretics are frequently recommended as initial therapy in patients with uncomplicated hypertension.<sup>30-35</sup> According to the National Heart, Lung, and Blood Institute's Eighth Report of The Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 8), thiazide-type diuretics should be utilized first-line for most patients with hypertension, either alone or in combination with another hypertensive from a different medication class (e.g., ACE inhibitors, ARBs,  $\beta$ -blockers, calcium channel blockers).<sup>30</sup> Several guidelines consistently recommend that the selection of an antihypertensive agent be based on compelling indications for use.<sup>30-38</sup> Most patients will require more than one antihypertensive medication to achieve blood pressure goals.<sup>30-37</sup>

In clinical trials, the ACE inhibitors have been shown to reduce cardiovascular morbidity and mortality, preserve renal function in patients with nephropathy, and effectively lower blood pressure when administered as monotherapy or in combination with other antihypertensive agents.<sup>39-150</sup> Most patients will need more than one antihypertensive agent to achieve blood pressure goals. The use of a fixed-dose combination product may simplify the treatment regimen and improve adherence.<sup>30-35,156-158</sup> However, there are no prospective, randomized trials that have demonstrated better clinical outcomes with a fixed-dose combination product compared to the coadministration of the individual components as separate formulations.

There is insufficient evidence to support that one brand angiotensin-converting enzyme inhibitor is safer or more efficacious than another. Formulations without a generic alternative should be managed through the medical justification portion of the prior authorization process.

Therefore, all brand angiotensin-converting enzyme inhibitors within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

## **XI. Recommendations**

No brand angiotensin-converting enzyme inhibitor is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

Pharmacotherapy Review of Angiotensin II Receptor Antagonists  
AHFS Class 243208  
May 4, 2022**

**I. Overview**

The renin-angiotensin-aldosterone system (RAAS) is the most important component in the homeostatic regulation of blood pressure. Excessive activity of the RAAS may lead to hypertension, as well as fluid and electrolyte disorders.<sup>1,2</sup> Renin catalyzes the conversion of angiotensinogen to angiotensin I. Angiotensin I is then cleaved to angiotensin II by angiotensin-converting enzyme (ACE). Angiotensin II may also be generated through other pathways (angiotensin I convertase).<sup>1</sup> Angiotensin II can increase blood pressure by direct vasoconstriction, as well as through actions on the brain and autonomic nervous system.<sup>1,2</sup> In addition, angiotensin II stimulates aldosterone synthesis from the adrenal cortex, leading to sodium and water reabsorption. Angiotensin II exerts other detrimental effects, including ventricular hypertrophy, remodeling, and myocyte apoptosis.<sup>1,2</sup>

The angiotensin II receptor antagonists are approved for the treatment of diabetic nephropathy, heart failure, hypertension and post-myocardial infarction.<sup>3-20</sup> Since angiotensin II may be generated through other pathways that do not depend upon ACE, blockade of angiotensin II by ACE inhibitors is incomplete. Angiotensin II receptor antagonists block the angiotensin II receptor subtype AT<sub>1</sub>, preventing the negative effects of angiotensin II, regardless of its origin. They do not appear to affect bradykinin and may be an option for patients who cannot tolerate ACE inhibitors.<sup>20,21</sup> The angiotensin II receptor antagonists are available as single entity products, as well as in combination with hydrochlorothiazide or chlorthalidone. Hydrochlorothiazide inhibits the reabsorption of sodium and chloride in the cortical thick ascending limb of the loop of Henle and the early distal tubules. This action leads to an increase in the urinary excretion of sodium and chloride. Telmisartan and olmesartan are also available in combination with amlodipine, a nondihydropyridine calcium-channel blocking agent, which is a potent vasodilator.<sup>20,21</sup>

The angiotensin II receptor antagonists that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. All single entity products with the exception of azilsartan are available generically. Fixed-dose combination products are available in a generic formulation with the exception of azilsartan-chlorthalidone. Byvalson<sup>®</sup> (neбиволол/valsartan) was discontinued in 2018. This class was last reviewed in February 2020.

**Table 1. Angiotensin II Receptor Antagonists Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
<b>Single Entity Agents</b>			
Azilsartan	tablet	Edarbi <sup>®</sup>	none
Candesartan	tablet	Atacand <sup>®*</sup>	candesartan
Irbesartan	tablet	Avapro <sup>®*</sup>	irbesartan
Losartan	tablet	Cozaar <sup>®*</sup>	losartan
Olmesartan	tablet	Benicar <sup>®*</sup>	olmesartan
Telmisartan	tablet	Micardis <sup>®*</sup>	telmisartan
Valsartan	tablet	Diovan <sup>®*</sup>	valsartan
<b>Combination Products</b>			
Azilsartan and chlorthalidone	tablet	Edarbyclor <sup>®</sup>	none
Candesartan and hydrochlorothiazide	tablet	Atacand HCT <sup>®*</sup>	candesartan and hydrochlorothiazide
Irbesartan and hydrochlorothiazide	tablet	Avalide <sup>®*</sup>	irbesartan and hydrochlorothiazide
Losartan and hydrochlorothiazide	tablet	Hyzaar <sup>®*</sup>	losartan and hydrochlorothiazide
Olmesartan and amlodipine and	tablet	Tribenzor <sup>®*</sup>	olmesartan and amlodipine

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
hydrochlorothiazide			and hydrochlorothiazide
Olmesartan and hydrochlorothiazide	tablet	Benicar HCT®*	olmesartan and hydrochlorothiazide
Telmisartan and amlodipine	tablet	N/A	telmisartan and amlodipine
Telmisartan and hydrochlorothiazide	tablet	Micardis HCT®*	telmisartan and hydrochlorothiazide
Valsartan and hydrochlorothiazide	tablet	Diovan HCT®*	valsartan and hydrochlorothiazide

\*Generic is available in at least one dosage form or strength.  
PDL=Preferred Drug List

## II. Evidence-Based Medicine and Current Treatment Guidelines

Current treatment guidelines that incorporate the use of the angiotensin II receptor antagonists are summarized in Table 2.

**Table 2. Treatment Guidelines Using the Angiotensin II Receptor Antagonists**

Clinical Guideline	Recommendations
American College of Cardiology/American Heart Association: <b>2007 Chronic Angina Focused Update of the 2002 Guidelines for the Management of Patients With Chronic Stable Angina (2007)</b> <sup>22</sup>	<ul style="list-style-type: none"> <li>Aspirin should be started at 75 to 162 mg/day and continued indefinitely in all patients, unless contraindicated.</li> <li>Use of warfarin in conjunction with aspirin and/or clopidogrel is associated with an increased risk of bleeding and should be monitored closely.</li> <li>Patients with hypertension and established coronary artery disease (CAD) should be treated with blood pressure medication(s) as tolerated, including angiotensin-converting enzyme inhibitors (ACE inhibitors) and/or <math>\beta</math>-adrenergic antagonists (<math>\beta</math>-blockers) with the addition of other medications as needed to achieve blood pressure goals of &lt;140/90 or &lt;130/80 mm Hg for patients with chronic kidney disease or diabetes.</li> <li>Long-acting calcium-channel blocking agents or long-acting nitrates may be used if <math>\beta</math>-blockers are contraindicated. Immediate-release and short-acting dihydropyridine calcium channel blockers can increase adverse cardiac events and should not be used.</li> <li>Long-acting calcium channel blockers or long-acting nitrates may be used with <math>\beta</math>-blockers if initial treatment is not successful.</li> <li>ACE inhibitors should be used indefinitely in patients with a left ventricular ejection fraction (LVEF) of <math>\leq 40\%</math> and in those with hypertension, diabetes or chronic kidney disease, unless contraindicated.</li> <li>ACE inhibitors should also be used indefinitely in patients at lower risk (mildly reduced or normal LVEF in whom cardiovascular risk factors remain well controlled and revascularization has been performed), unless contraindicated.</li> <li>Angiotensin II receptor blockers (ARBs) are recommended in patients with hypertension, those who have an indication for an ACE inhibitor and are intolerant to them, who have heart failure, or who have had a myocardial infarction (MI) and have a LVEF of <math>\leq 40\%</math>.</li> <li>ARBs may be considered in combination with an ACE inhibitor for heart failure due to left ventricular systolic dysfunction.</li> <li>Aldosterone blockade is recommended in patients post-MI without significant renal dysfunction or hyperkalemia who are already receiving therapeutic doses of an ACE inhibitor and a <math>\beta</math>-blocker, have a LVEF <math>\leq 40\%</math> and have either diabetes or heart failure.</li> <li>It is beneficial to start and continue <math>\beta</math>-blocker therapy indefinitely in all patients who have had a MI, acute coronary syndrome or left ventricular dysfunction with or without heart failure symptoms, unless contraindicated.</li> </ul>

Clinical Guideline	Recommendations
<p>European Society of Cardiology: <b>Guidelines for the Diagnosis and Management of Chronic Coronary Syndromes (2019)</b><sup>23</sup></p>	<ul style="list-style-type: none"> <li>• Annual influenza vaccination is recommended in patients with cardiovascular disease.</li> </ul> <p><b>Pharmacological management of stable coronary artery disease (CAD) patients</b></p> <ul style="list-style-type: none"> <li>• The two aims of the pharmacological management of stable CAD patients are to obtain relief of symptoms and to prevent CV events.</li> <li>• Optimal medical treatment indicates at least one drug for angina/ischemia relief plus drugs for event prevention.</li> <li>• It is recommended to educate patients about the disease, risk factors and treatment strategy.</li> <li>• It is indicated to review the patient's response soon after starting therapy.</li> <li>• Concomitant use of a proton pump inhibitor is recommended in patients receiving aspirin monotherapy, DAPT, or DOAC monotherapy who are at high risk of gastrointestinal bleeding.</li> <li>• Lipid-lowering drugs: if goals are not met on maximum tolerated dose of a statin, consideration of combination therapy with ezetimibe or a PCSK9 inhibitor is recommended</li> <li>• ACE inhibitors should be considered in patients at a very high risk of cardiovascular adverse events</li> <li>• Angina/ischemia relief:             <ul style="list-style-type: none"> <li>○ Short-acting nitrates are recommended.</li> <li>○ First-line treatment is indicated with <math>\beta</math>-blockers and/or calcium channel blockers to control heart rate and symptoms.</li> <li>○ Long-acting nitrates should be considered as a second-line treatment option when initial therapy with a beta-blocker and/or a non-DHP-calcium channel blocker is contraindicated, poorly tolerated, or inadequate in controlling angina symptoms</li> <li>○ Nicorandil, ranolazine, ivabradine, or trimetazidine should be considered as a second-line treatment to reduce angina frequency and improve exercise tolerance in subjects who cannot tolerate, have contraindications to, or whose symptoms are not adequately controlled by beta-blockers, CCBs, and long-acting nitrates.</li> <li>○ According to comorbidities/tolerance, it is indicated to use second-line therapies as first-line treatment in selected patients.</li> <li>○ In asymptomatic patients with large areas of ischaemia (&gt;10%) <math>\beta</math>-blockers should be considered.</li> <li>○ In patients with vasospastic angina, calcium channel blockers and nitrates should be considered and beta-blockers avoided.</li> </ul> </li> <li>• Event prevention:             <ul style="list-style-type: none"> <li>○ Low-dose aspirin daily is recommended in all stable CAD patients.</li> <li>○ Clopidogrel is indicated as an alternative in case of aspirin intolerance.</li> <li>○ Statins are recommended in all stable CAD patients.</li> <li>○ It is recommended to use ACE inhibitors (or ARBs) if presence of other conditions (e.g., heart failure, hypertension or diabetes).</li> </ul> </li> </ul> <p><b>Treatment in patients with microvascular angina</b></p> <ul style="list-style-type: none"> <li>• It is recommended that all patients receive secondary prevention medications including aspirin and statins.</li> <li>• <math>\beta</math>-blockers are recommended as a first-line treatment.</li> <li>• Calcium antagonists are recommended if <math>\beta</math>-blockers do not achieve sufficient symptomatic benefit or are not tolerated.</li> <li>• ACE inhibitors or nicorandil may be considered in patients with refractory symptoms.</li> <li>• Xanthine derivatives or nonpharmacological treatments such as neurostimulatory techniques may be considered in patients with symptoms refractory to the above listed drugs.</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Stenting and peri-procedural antiplatelet strategies in stable CAD patients</u></p> <ul style="list-style-type: none"> <li>• Drug-eluting stent (DES) is recommended in stable CAD patients undergoing stenting if there is no contraindication to prolonged dual antiplatelet therapy (DAPT).</li> <li>• Aspirin is recommended for elective stenting.</li> <li>• Clopidogrel is recommended for elective stenting.</li> <li>• Prasugrel or ticagrelor should be considered in patients with stent thrombosis on clopidogrel without treatment interruption.</li> <li>• GP IIb/IIIa antagonists should be considered for bailout situation only.</li> <li>• Platelet function testing or genetic testing may be considered in specific or high risk situations (e.g., prior history of stent thrombosis; compliance issue; suspicion of resistance; high bleeding risk) if results may change the treatment strategy.</li> <li>• Prasugrel or ticagrelor may be considered in specific high risk situations of elective stenting (e.g., left main stenting, high risk of stent thrombosis, diabetes).</li> <li>• Pretreatment with clopidogrel (when coronary anatomy is not known) is not recommended.</li> <li>• Routine platelet function testing (clopidogrel and aspirin) to adjust antiplatelet therapy before or after elective stenting is not recommended.</li> <li>• Prasugrel or ticagrelor is not recommended in low risk elective stenting.</li> <li>• After uncomplicated PCI, early cessation (<math>\leq 1</math> week) of aspirin, and continuation of dual therapy with oral anticoagulation therapy and clopidogrel should be considered if the risk of stent thrombosis is low</li> <li>• Triple therapy with aspirin, clopidogrel, and a DOAC for <math>\geq 1</math> month should be considered when the risk of stent thrombosis outweighs the bleeding risk, with a total of no more than six months</li> </ul> <p><u>Follow-up of revascularized stable coronary artery disease patients</u></p> <ul style="list-style-type: none"> <li>• It is recommended that all revascularized patients receive a secondary prevention and be scheduled for follow-up visit.</li> <li>• It is recommended to instruct patients before discharge about return to work and resumption of full activities. Patients have to be advised to seek immediate medical contact if symptoms (re-) occur.</li> <li>• Single antiplatelet therapy, usually aspirin, is recommended indefinitely.</li> <li>• DAPT is indicated after bare metal stent (BMS) for at least one month.</li> <li>• DAPT is indicated for six to 12 months after second generation DES.</li> <li>• DAPT may be used for more than one year in patients at high ischemic risk (e.g., stent thrombosis, recurrent acute coronary syndrome on DAPT, post MI/diffuse CAD) and low bleeding risk.</li> <li>• DAPT for one to three months may be used after DES implantation in patients at high bleeding risk or with undeferrable surgery or concomitant anticoagulant treatment.</li> </ul> <p><u>Antithrombotic therapy in patients with chronic coronary syndrome:</u></p> <ul style="list-style-type: none"> <li>• Addition of a second antithrombotic drug to aspirin for long-term secondary prevention should be considered in patients with at least a moderately increased risk of ischemic events and without high bleeding risk</li> <li>• When oral anticoagulation is initiated in patients with AF, a DOAC is recommended in preference to VKA therapy.</li> </ul>
<p>American College of Physicians/ American College of Cardiology Foundation/ American Heart Association/ American Association</p>	<p><u>Medical therapy to prevent MI and death in patients with stable IHD</u></p> <ul style="list-style-type: none"> <li>• Aspirin 75 to 162 mg daily should be continued indefinitely in the absence of contraindications.</li> <li>• Treatment with clopidogrel is a reasonable option when aspirin is contraindicated.</li> <li>• Dipyridamole should not be used as antiplatelet therapy.</li> </ul>

Clinical Guideline	Recommendations
<p>for Thoracic Surgery/ Preventive Cardiovascular Nurses Association/ Society of Thoracic Surgeons: <b>Management of Stable Ischemic Heart Disease (2012)</b><sup>24</sup></p>	<ul style="list-style-type: none"> <li>• Beta-blocker therapy should be initiated and continued for three years in all patients with normal left ventricular (LV) function following MI or acute coronary syndromes.</li> <li>• Metoprolol succinate, carvedilol, or bisoprolol should be used for all patients with systolic LV dysfunction (ejection fraction <math>\leq 40\%</math>) with heart failure or prior MI, unless contraindicated.</li> <li>• ACE inhibitors should be prescribed in all patients with stable IHD who also have hypertension, diabetes, LV systolic dysfunction (ejection fraction <math>\leq 40\%</math>), and/or chronic kidney disease, unless contraindicated.</li> <li>• Angiotensin-receptor blockers (ARBs) are recommended for patients with stable IHD who have hypertension, diabetes, LV systolic dysfunction, or chronic kidney disease and have indications for, but are intolerant of, ACE inhibitors.</li> <li>• Patients should receive an annual influenza vaccine.</li> </ul> <p><u>Medical therapy for relief of symptoms in patients with stable IHD</u></p> <ul style="list-style-type: none"> <li>• Beta-blockers are recommended as initial therapy for relief of symptoms.</li> <li>• Calcium channel blockers or long-acting nitrates should be prescribed for relief of symptoms when <math>\beta</math>-blockers are contraindicated or cause unacceptable side effects.</li> <li>• Calcium channel blockers or long-acting nitrates, in combination with <math>\beta</math>-blockers, should be prescribed for relief of symptoms when initial treatment with <math>\beta</math>-blockers is unsuccessful.</li> <li>• Nitroglycerin or nitroglycerin spray should be used for immediate relief of angina.</li> <li>• Ranolazine is a fourth-line agent reserved for patients who have contraindications to, do not respond to, or cannot tolerate <math>\beta</math>-blockers, calcium-channel blockers, or long-acting nitrates.</li> </ul>
<p>American College of Cardiology Foundation/American Heart Association: <b>2014 American Heart Association/ American College of Cardiology Foundation Guideline for the Management of Patients With Non-ST-Elevation Acute Coronary Syndromes (2014)</b><sup>25</sup></p>	<p><u>Early hospital care- standard medical therapies</u></p> <ul style="list-style-type: none"> <li>• Supplemental oxygen should be administered to patients with non-ST-elevation acute coronary syndrome (NSTEMI-ACS) with arterial oxygen saturation <math>&lt; 90\%</math>, respiratory distress, or other high risk features of hypoxemia.</li> <li>• Anti-ischemic and analgesic medications             <ul style="list-style-type: none"> <li>○ Nitrates                 <ul style="list-style-type: none"> <li>▪ Patients with NSTEMI-ACS with continuing ischemic pain should receive sublingual nitroglycerin (0.3 to 0.4 mg) every 5 minutes for up to three doses, after which an assessment should be made about the need for intravenous nitroglycerin.</li> <li>▪ Intravenous nitroglycerin is indicated for patients with NSTEMI-ACS for the treatment of persistent ischemia, heart failure, or hypertension.</li> <li>▪ Nitrates should not be administered to patients who recently received a phosphodiesterase inhibitor, especially within 24 hours of sildenafil or vardenafil, or within 48 hours of tadalafil.</li> </ul> </li> <li>○ Analgesic therapy                 <ul style="list-style-type: none"> <li>▪ In the absence of contraindications, it may be reasonable to administer morphine sulphate intravenously to patients with NSTEMI-ACS if there is continued ischemic chest pain despite treatment with maximally tolerated anti-ischemic medications.</li> <li>▪ Nonsteroidal anti-inflammatory drugs (NSAIDs) (except aspirin) should not be initiated and should be discontinued during hospitalization due to the increased risk of major adverse cardiac event associated with their use</li> </ul> </li> <li>○ Beta-adrenergic blockers                 <ul style="list-style-type: none"> <li>▪ Oral <math>\beta</math>-blocker therapy should be initiated within the first 24 hours in patients who do not have any of the following: 1) signs of HF, 2) evidence of low-output state, 3) increased risk for cardiogenic shock,</li> </ul> </li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>or 4) other contraindications to <math>\beta</math>-blockade (e.g., PR interval <math>&gt;0.24</math> second, second- or third-degree heart block without a cardiac pacemaker, active asthma, or reactive airway disease)</p> <ul style="list-style-type: none"> <li>▪ In patients with concomitant NSTEMI-ACS, stabilized heart failure, and reduced systolic function, it is recommended to continue <math>\beta</math>-blocker therapy with one of the three drugs proven to reduce mortality in patients with heart failure: sustained-release metoprolol succinate, carvedilol, or bisoprolol.</li> <li>▪ Patients with documented contraindications to <math>\beta</math>-blockers in the first 24 hours should be re-evaluated to determine subsequent eligibility.</li> </ul> <p>○ Calcium channel blockers (CCBs)</p> <ul style="list-style-type: none"> <li>▪ In patients with NSTEMI-ACS, continuing or frequently recurring ischemia, and a contraindication to <math>\beta</math>-blockers, a nondihydropyridine CCB (e.g., verapamil or diltiazem) should be given as initial therapy in the absence of clinically significant LV dysfunction, increased risk for cardiogenic shock, PR interval <math>&gt;0.24</math> seconds, or second or third degree atrioventricular block without a cardiac pacemaker.</li> <li>▪ Oral nondihydropyridine calcium antagonists are recommended in patients with NSTEMI-ACS who have recurrent ischemia in the absence of contraindications, after appropriate use of <math>\beta</math>-blockers and nitrates.</li> <li>▪ CCBs are recommended for ischemic symptoms when <math>\beta</math>-blockers are not successful, are contraindicated, or cause unacceptable side effects.</li> <li>▪ Long-acting CCBs and nitrates are recommended in patients with coronary artery spasm.</li> <li>▪ Immediate-release nifedipine should not be administered to patients with NSTEMI-ACS in the absence of <math>\beta</math>-blocker therapy.</li> </ul> <p>○ Other anti-ischemic interventions</p> <ul style="list-style-type: none"> <li>▪ Ranolazine is currently indicated for treatment of chronic angina; however, it may also improve outcomes in NSTEMI-ACS patients due to a reduction in recurrent ischemia.</li> </ul> <p>○ Cholesterol management</p> <ul style="list-style-type: none"> <li>▪ High-intensity statin therapy should be initiated or continued in all patients with NSTEMI-ACS and no contraindications to its use. Treatment with statins reduces the rate of recurrent MI, coronary heart disease mortality, need for myocardial revascularization, and stroke.</li> <li>▪ It is reasonable to obtain a fasting lipid profile in patients with NSTEMI-ACS, preferably within 24 hours of presentation.</li> </ul> <p>● Inhibitors of renin-angiotensin-aldosterone system</p> <ul style="list-style-type: none"> <li>○ ACE inhibitors should be started and continued indefinitely in all patients with LVEF <math>&lt;0.40</math> and in those with hypertension, diabetes mellitus, or stable CKD, unless contraindicated.</li> <li>○ ARBs are recommended in patients with heart failure or myocardial infarction with LVEF <math>&lt;0.40</math> who are ACE inhibitor intolerant.</li> <li>○ Aldosterone-blockade is recommended in patients post-MI without significant renal dysfunction (creatinine <math>&gt;2.5</math> mg/dL in men or <math>&gt;2.0</math> mg/dL in women) or hyperkalemia (<math>K &gt;5.0</math> mEq/L) who are receiving therapeutic doses of ACE inhibitor and <math>\beta</math>-blocker and have a LVEF <math>&lt;0.40</math>, diabetes mellitus, or heart failure.</li> </ul> <p>● Initial antiplatelet/anticoagulant therapy in patients with definite or likely NSTEMI-ACS treated with an initial invasive or ischemia-guided strategy</p> <ul style="list-style-type: none"> <li>○ Non-enteric coated, chewable aspirin (162 to 325 mg) should be given to all patients with NSTEMI-ACS without contraindications as soon as possible after presentation, and a maintenance dose of aspirin (81 to 162 mg/day) should be continued indefinitely.</li> <li>○ In patients who are unable to take aspirin because of hypersensitivity or major gastrointestinal intolerance, a loading dose of clopidogrel followed by</li> </ul>

Clinical Guideline	Recommendations
	<p>a daily maintenance dose should be administered.</p> <ul style="list-style-type: none"> <li>○ A P2Y<sub>12</sub> receptor inhibitor (clopidogrel or ticagrelor) in addition to aspirin should be administered for up to 12 months to all patients with NSTEMI-ACS without contraindications who are treated with an early invasive or ischemia-guided strategy. Options include: <ul style="list-style-type: none"> <li>▪ Clopidogrel: 300 or 600 mg loading dose, then 75 mg daily.</li> <li>▪ Ticagrelor: 180 mg loading dose, then 90 mg twice daily.</li> <li>▪ It is reasonable to use ticagrelor in preference to clopidogrel for P2Y<sub>12</sub> treatment in patients with NSTEMI-ACS who undergo an early invasive or ischemia-guided strategy.</li> <li>▪ In patients with NSTEMI-ACS treated with an early invasive strategy and dual antiplatelet therapy (DAPT) with intermediate/high-risk features (e.g., positive troponin), a GP IIb/IIIa inhibitor may be considered as part of initial antiplatelet therapy. Preferred options are eptifibatid or tirofiban.</li> </ul> </li> </ul> <p><u>Percutaneous coronary intervention (PCI)- Antiplatelet and anticoagulant therapy</u></p> <ul style="list-style-type: none"> <li>● Antiplatelet agents <ul style="list-style-type: none"> <li>○ Patients already taking daily aspirin before PCI should take 81 to 325 mg non-enteric coated aspirin before PCI</li> <li>○ Patients not on aspirin therapy should be given non-enteric coated aspirin 325 mg as soon as possible before PCI.</li> <li>○ After PCI, aspirin should be continued indefinitely.</li> <li>○ A loading dose of a P2Y<sub>12</sub> inhibitor should be given before the procedure in patients undergoing PCI with stenting. Options include clopidogrel 600 mg, prasugrel 60 mg, or ticagrelor 180 mg.</li> <li>○ In patients with NSTEMI-ACS and high-risk features (e.g., elevated troponin) not adequately pretreated with clopidogrel or ticagrelor, it is useful to administer a GP IIb/IIIa inhibitor (abciximab, double-bolus eptifibatid, or high-dose bolus tirofiban) at the time of PCI.</li> <li>○ In patients receiving a stent (bare metal or drug eluting) during PCI, P2Y<sub>12</sub> inhibitor therapy should be given for at least 12 months. Options include clopidogrel 75 mg daily, prasugrel 10 mg daily, or ticagrelor 90 mg twice daily.</li> </ul> </li> <li>● Anticoagulant therapy <ul style="list-style-type: none"> <li>○ An anticoagulant should be administered to patients with NSTEMI-ACS undergoing PCI to reduce the risk of intracoronary and catheter thrombus formation.</li> <li>○ Intravenous unfractionated heparin (UFH) is useful in patients with NSTEMI-ACS undergoing PCI.</li> <li>○ Bivalirudin is useful as an anticoagulant with or without prior treatment with UFH.</li> <li>○ An additional dose of 0.3 mg/kg intravenous enoxaparin should be administered at the time of PCI to patients with NSTEMI-ACS who have received fewer than two therapeutic subcutaneous doses or received the last subcutaneous enoxaparin dose eight to 12 hours before PCI.</li> <li>○ If PCI is performed while the patient is on fondaparinux, an additional 85 IU/kg of UFH should be given intravenously immediately before PCI because of the risk of catheter thrombosis (60 IU/kg IV if a GP IIb/IIIa inhibitor used with UFH dosing based on the target-activated clotting time).</li> <li>○ Anticoagulant therapy should be discontinued after PCI unless there is a compelling reason to continue.</li> </ul> </li> <li>● Timing of CABG in relation to use of antiplatelet agents <ul style="list-style-type: none"> <li>○ Non-enteric coated aspirin (81 to 325 mg daily) should be administered preoperatively to patients undergoing CABG.</li> <li>○ In patients referred for elective CABG, clopidogrel and ticagrelor should be</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>discontinued for at least five days before surgery and prasugrel for at least seven days before surgery.</p> <ul style="list-style-type: none"> <li>○ In patients referred for urgent CABG, clopidogrel and ticagrelor should be discontinued for at least 24 hours to reduce major bleeding.</li> <li>○ In patients referred for CABG, short-acting intravenous GP IIb/IIIa inhibitors (eptifibatide or tirofiban) should be discontinued for at least 2 to 4 hours before surgery and abciximab for at least 12 hours before to limit blood loss and transfusion.</li> </ul> <p><u>Late hospital care, hospital discharge, and posthospital discharge care</u></p> <ul style="list-style-type: none"> <li>● Medications at discharge <ul style="list-style-type: none"> <li>○ Medications required in the hospital to control ischemia should be continued after hospital discharge in patients with NSTEMI-ACS who do not undergo coronary revascularization, patients with incomplete or unsuccessful revascularization, and patients with recurrent symptoms after revascularization. Titration of the doses may be required.</li> <li>○ All patients who are post-NSTEMI-ACS should be given sublingual or spray nitroglycerin with verbal and written instructions for its use.</li> <li>○ Before hospital discharge, patients with NSTEMI-ACS should be informed about symptoms of worsening myocardial ischemia and MI and should be given verbal and written instructions about how and when to seek emergency care for such symptoms.</li> <li>○ Before hospital discharge, patients who are post-NSTEMI-ACS and/or designated responsible caregivers should be provided with easily understood and culturally sensitive verbal and written instructions about medication type, purpose, dose, frequency, side effects, and duration of use.</li> <li>○ For patients who are post-NSTEMI-ACS and have initial angina lasting more than one minute, nitroglycerin (one dose sublingual or spray) is recommended if angina does not subside within three to five minutes; call 9-1-1 immediately to access emergency medical services.</li> <li>○ If the pattern or severity of angina changes, suggesting worsening myocardial ischemia (e.g., pain is more frequent or severe or is precipitated by less effort or occurs at rest), patients should contact their clinician without delay to assess the need for additional treatment or testing.</li> <li>○ Before discharge, patients should be educated about modification of cardiovascular risk factors.</li> </ul> </li> <li>● Late hospital and post-hospital oral antiplatelet therapy <ul style="list-style-type: none"> <li>○ Aspirin should be continued indefinitely. The dose should be 81 mg daily in patients treated with ticagrelor and 81 to 325 mg daily in all other patients.</li> <li>○ In addition to aspirin, a P2Y<sub>12</sub> inhibitor (either clopidogrel or ticagrelor) should be continued for up to 12 months in all patients with NSTEMI-ACS without contraindications who are treated with an ischemia-guided strategy.</li> <li>○ In patients receiving a stent (bare-metal stent or DES) during PCI for NSTEMI-ACS, P2Y<sub>12</sub> inhibitor therapy should be given for at least 12 months.</li> </ul> </li> <li>● Combined oral anticoagulant therapy and antiplatelet therapy in patients with NSTEMI-ACS <ul style="list-style-type: none"> <li>○ The duration of triple antithrombotic therapy with a vitamin K antagonist, aspirin, and a P2Y<sub>12</sub> receptor inhibitor in patients with NSTEMI-ACS should be minimized to the extent possible to limit the risk of bleeding.</li> <li>○ Proton pump inhibitors should be prescribed in patients with NSTEMI-ACS with a history of gastrointestinal bleeding who require triple antithrombotic therapy with a vitamin K antagonist, aspirin, and a P2Y<sub>12</sub> receptor inhibitor.</li> </ul> </li> </ul>

<p><b>Management of Acute Coronary Syndromes in Patients Presenting without Persistent ST-Segment Elevation (2020)</b><sup>26</sup></p>	<p>contraindications.</p> <ul style="list-style-type: none"> <li>• Continuation of chronic <math>\beta</math>-blocker therapy is recommended unless the patient is in overt heart failure</li> <li>• Sublingual or intravenous nitrates are recommended to relieve angina; intravenous treatment is recommended in patients with recurrent angina, uncontrolled hypertension, or signs of heart failure.</li> <li>• In patients with suspected/confirmed vasospastic angina, calcium channel blockers, and nitrates should be considered and <math>\beta</math>-blockers avoided.</li> </ul> <p><u>Recommendations for platelet inhibition in non-ST-elevation acute coronary syndromes</u></p> <ul style="list-style-type: none"> <li>• Aspirin is recommended for all patients without contraindications at an initial oral loading dose of 150 to 300 mg (in aspirin-naïve patients) and a maintenance dose of 75 to 100 mg/day long-term regardless of treatment strategy.</li> <li>• A P2Y<sub>12</sub> inhibitor is recommended, in addition to aspirin, for 12 months unless there are contraindications such as excessive risks of bleeds. <ul style="list-style-type: none"> <li>○ Ticagrelor (180 mg loading dose, 90 mg twice daily) is recommended, in the absence of contraindication, for all patients at moderate-to-high risk of ischemic events (e.g., elevated cardiac troponins), regardless of initial treatment strategy and including those pretreated with clopidogrel (which should be discontinued when ticagrelor is started).</li> <li>○ Prasugrel (60 mg loading dose, 10 mg daily dose) is recommended in patients who are proceeding to PCI if no contraindication. Prasugrel should be considered in preference to ticagrelor in NSTEMI-ACS patients who proceed to PCI.</li> <li>○ Clopidogrel (300 to 600 mg loading dose, 75 mg daily dose) is recommended for patients who cannot receive ticagrelor or prasugrel or who require oral anticoagulation.</li> </ul> </li> <li>• P2Y<sub>12</sub> inhibitor administration for a shorter duration of three to six months after DES implantation may be considered in patients deemed at high bleeding risk.</li> <li>• Pre-treatment with a P2Y<sub>12</sub> inhibitor may be considered in patients with NSTEMI-ACS who are not planned to undergo an early invasive strategy.</li> <li>• It is not recommended to administer routine pre-treatment with a P2Y<sub>12</sub> inhibitor in patients in whom coronary anatomy is not known.</li> <li>• It is not recommended to administer prasugrel in patients whom coronary anatomy is not known.</li> <li>• GPIIb/IIIa inhibitors during PCI should be considered for bailout situations or thrombotic complications.</li> <li>• Cangrelor may be considered in P2Y<sub>12</sub> inhibitor-naïve patients undergoing PCI.</li> <li>• It is not recommended to administer GPIIb/IIIa inhibitors in patients whom coronary anatomy is not known.</li> <li>• P2Y<sub>12</sub> inhibitor administration in addition to aspirin beyond one year may be considered after careful assessment of the ischemic and bleeding risks of the patient.</li> </ul> <p><u>Recommendations for anticoagulation in non-ST-elevation acute coronary syndromes</u></p> <ul style="list-style-type: none"> <li>• Parenteral anticoagulation is recommended at the time of diagnosis according to both ischemic and bleeding risks.</li> <li>• Fondaparinux is recommended as having the most favorable efficacy-safety profile regardless of the management strategy.</li> <li>• Bivalirudin is recommended as an alternative to UFH plus GPIIb/IIIa inhibitors during PCI.</li> <li>• UFH is recommended in patients undergoing PCI who did not receive any anticoagulant.</li> <li>• In patients on fondaparinux undergoing PCI, a single intravenous bolus of UFH</li> </ul>

Clinical Guideline	Recommendations
	<p>is recommended during the procedure.</p> <ul style="list-style-type: none"> <li>• Enoxaparin or UFH are recommended when fondaparinux is not available.</li> <li>• Enoxaparin should be considered as an anticoagulant for PCI in patients pretreated for PCI with subcutaneous enoxaparin.</li> <li>• Additional activated clotting time-guided intravenous boluses of UFH during PCI may be considered following initial UFH treatment.</li> <li>• Discontinuation of anticoagulation should be considered after PCI, unless otherwise indicated.</li> <li>• Crossover between UFH and LMWH is not recommended.</li> <li>• In NSTEMI patients with no prior stroke/TIA and at high ischemic risk as well as low bleeding risk receiving aspirin and clopidogrel, low-dose rivaroxaban (2.5 mg twice daily for approximately one year) may be considered after discontinuation of parenteral anticoagulation.</li> </ul> <p><u>Recommendations for combining antiplatelet agents and anticoagulants in non-ST-elevation acute coronary syndrome patients requiring chronic oral anticoagulation</u></p> <ul style="list-style-type: none"> <li>• In patients with a firm indication for oral anticoagulation (e.g., atrial fibrillation with a CHADS<sub>2</sub>-VASc score <math>\geq 2</math>, recent VTE, mechanical valve prosthesis), oral anticoagulation is recommended in addition to antiplatelet therapy.</li> <li>• An early invasive coronary angiography (within 24 hours) should be considered in moderate- to high-risk patients, irrespective of oral anticoagulant exposure, to expedite treatment allocation (medical vs PCI vs CABG) and to determine optimal antithrombotic regimen.</li> <li>• Initial dual antiplatelet therapy with aspirin plus a P2Y<sub>12</sub> inhibitor in addition to oral anticoagulation before coronary angiography is not recommended.</li> <li>• During PCI, additional parenteral anticoagulation is recommended, irrespective of the timing of the last dose of all non-vitamin K antagonist oral anticoagulants (NOACs) and if INR is <math>&lt; 2.5</math> in VKA-treated patients.</li> <li>• Uninterrupted therapeutic anticoagulation with VKA or NOACs should be considered during the periprocedural phase.</li> <li>• Periprocedural DAPT administration consisting of aspirin and clopidogrel up to one week is recommended</li> <li>• Discontinuation of antiplatelet treatment in patients treated with an oral anticoagulant is recommended after 12 months</li> <li>• Following coronary stenting, dual (oral) antiplatelet therapy (DAPT) including new P2Y<sub>12</sub> inhibitors should be considered as an alternative to triple therapy for patients with non-ST-elevation acute coronary syndromes and atrial fibrillation with a CHADS<sub>2</sub>-VASc score of 1 (in males) or 2 (in females).</li> <li>• If at low bleeding risk (HAS-BLED <math>\leq 2</math>), triple therapy with oral anticoagulant, aspirin, and clopidogrel should be considered for six months, followed by oral anticoagulant and aspirin or clopidogrel continued up to 12 months.</li> <li>• If at high bleeding risk (HAS-BLED <math>\geq 3</math>), triple therapy with oral anticoagulant, aspirin, and clopidogrel should be considered for one month, followed by oral anticoagulant and aspirin or clopidogrel continued up to 12 months irrespective of the stent type.</li> <li>• Dual therapy with oral anticoagulant and clopidogrel may be considered as an alternative to triple antithrombotic therapy in selected patients (HAS-BLED <math>\geq 3</math> and low risk of stent thrombosis).</li> <li>• The use of ticagrelor or prasugrel as part of triple therapy is not recommended.</li> <li>• In medically managed patients, one antiplatelet agent in addition to oral anticoagulant should be considered for up to one year.</li> </ul> <p><u>Recommendations for post-interventional and maintenance treatment</u></p> <ul style="list-style-type: none"> <li>• In patients with NSTEMI-ACS with coronary stent implantation, DAPT with a P2Y<sub>12</sub> inhibitor on top of aspirin is recommended for 12 months unless there are</li> </ul>

Clinical Guideline	Recommendations
	<p>contraindications such as excessive risk of bleeding.</p> <ul style="list-style-type: none"> <li>• Adding a second anti-thrombotic agent to aspirin for extended long-term secondary prevention should be considered in patients with a moderate to high risk of ischemic events and without increased risk of major bleeding.</li> <li>• After stent implantation with high risk of bleeding, discontinuation of P2Y<sub>12</sub> inhibitor therapy after three months should be considered</li> <li>• After stent implantation in patients undergoing DAPT, stopping aspirin after three to six months should be considered, depending on balance between ischemic and bleeding risk.</li> <li>• De-escalation of P2Y<sub>12</sub> inhibitor treatment may be considered as an alternative DAPT strategy, especially for ACS patients deemed unsuitable for potent platelet inhibition.</li> </ul>
<p>American College of Cardiology/American Heart Association: <b>Guideline for the Management of ST-Elevation Myocardial Infarction (2013)</b><sup>27</sup></p>	<p><u>Routine medical therapies: <math>\beta</math>-blockers</u></p> <ul style="list-style-type: none"> <li>• Oral <math>\beta</math>-blockers should be initiated within the first 24 hours in patients with an ST-segment elevation myocardial infarction (STEMI) who do not have any of the following: 1) signs of heart failure, 2) evidence of a low-output state, 3) increased risk of cardiogenic shock, 4) other contraindications to use of oral <math>\beta</math>-blockers (e.g., PR interval &gt;24 seconds, second or third degree heart block, active asthma, reactive airway disease).</li> <li>• <math>\beta</math>-blockers should be continued during and after hospitalization for all patients with STEMI and with no contraindications to their use.</li> <li>• Patients with initial contraindications to the use of <math>\beta</math>-blockers in the first 24 hours after STEMI should be re-evaluated to determine their subsequent eligibility.</li> <li>• It is reasonable to administer intravenous <math>\beta</math>-blockers at the time of presentation to patients with STEMI and no contraindications to their use who are hypertensive or have ongoing ischemia.</li> </ul> <p><u>Routine medical therapies: renin-angiotensin-aldosterone system inhibitors</u></p> <ul style="list-style-type: none"> <li>• An ACE inhibitor should be administered within the first 24 hours to all patients with ST-segment elevation myocardial infarction with anterior location, heart failure, or ejection fraction <math>\leq 40\%</math>, unless contraindicated.</li> <li>• An ARB should be given to patients who have indications for but are intolerant of ACE inhibitors.</li> <li>• ACE inhibitors are reasonable for all patients with no contraindications to their use.</li> <li>• An aldosterone antagonist should be given to patients with STEMI and no contraindications who are already receiving an ACE inhibitor and <math>\beta</math>-blocker and who have an EF <math>\leq 40\%</math> and either symptomatic heart failure or diabetes.</li> </ul> <p><u>Routine medical therapies: Lipid management</u></p> <ul style="list-style-type: none"> <li>• High-intensity statin therapy should be initiated or continued in all patients with STEMI and no contraindications to its use.</li> <li>• It is reasonable to obtain a fasting lipid profile in patients with STEMI, preferably within 24 hours of presentation.</li> </ul>
<p>European Society of Cardiology: <b>Management of Acute Myocardial Infarction in Patients Presenting with ST-segment Elevation (2017)</b><sup>28</sup></p>	<p><u>Routine therapies in the acute, subacute and long term phase of ST-elevation myocardial infarction (STEMI)</u></p> <ul style="list-style-type: none"> <li>• Antiplatelet therapy with low dose aspirin (75 to 100 mg) is indicated indefinitely after STEMI.</li> <li>• Dual antiplatelet therapy with a combination of aspirin and prasugrel or aspirin and ticagrelor is recommended for 12 months after percutaneous coronary intervention (PCI), unless there are contraindications such as excessive risk of bleeding.</li> <li>• A proton pump inhibitor (PPI) in combination with dual antiplatelet therapy is recommended in patients at high risk of gastrointestinal bleeding.</li> <li>• In patients with an indication for oral anticoagulation, oral anticoagulants are</li> </ul>

Clinical Guideline	Recommendations
	<p>indicated in addition to antiplatelet therapy.</p> <ul style="list-style-type: none"> <li>• In patients who are at high risk of severe bleeding complications, discontinuation of P2Y<sub>12</sub> inhibitor therapy after six months should be considered.</li> <li>• In STEMI patients with stent implantation and an indication for oral anticoagulation, triple therapy (oral anticoagulant, aspirin, and clopidogrel) should be considered for one to six months (according a balance between the estimated risk of recurrent coronary events and bleeding).</li> <li>• In patients with left ventricular thrombus, anticoagulation should be instituted for a minimum of six months, guided by repeated imaging.</li> <li>• In selected patients who receive aspirin and clopidogrel, low-dose rivaroxaban (2.5 mg twice daily) may be considered if the patient is at low bleeding risk.</li> <li>• Dual antiplatelet therapy should be used up to one year in patients with STEMI who did not receive a stent unless there are contraindications such as excessive risk of bleeding.</li> <li>• In high ischemic-risk patients (age ≥50 years, and at least one of the following risk factors: age ≥65 years, diabetes mellitus on medication, prior spontaneous MAI, multivessel CAD, or chronic renal dysfunction with eGFR &lt;60 mL/min) who have tolerated dual antiplatelet therapy without a bleeding complication, treatment with dual antiplatelet therapy in the form of ticagrelor 60 mg twice a day on top of aspirin for longer than 12 months may be considered for up to three years.</li> <li>• The use of ticagrelor or prasugrel is not recommended as part of triple antithrombotic therapy with aspirin and oral anticoagulation.</li> <li>• Oral treatment with β-blockers should be considered during hospital stay and continued thereafter in all patients without contraindications.</li> <li>• Oral treatment with β-blockers is indicated in patients with heart failure or left ventricular dysfunction, LVEF ≤40% unless contraindicated.</li> <li>• Intravenous β-blockers must be avoided in patients with hypotension or acute heart failure or AV block or severe bradycardia.</li> <li>• Intravenous β-blockers should be considered at the time of presentation in patients undergoing primary PCI without contraindications, with high blood pressure, tachycardia, and no signs of heart failure.</li> <li>• A fasting lipid profile must be obtained in all STEMI patients, as soon as possible after presentation.</li> <li>• It is recommended to initiate or continue high dose statins early after admission in all STEMI patients without contraindication or history of intolerance, regardless of initial cholesterol values and maintain it long-term.</li> <li>• An LDL-C goal of &lt;1.8 mmol/L (70 mg/dL) or a reduction of at least 50% if the baseline LDL-C is between 1.8 to 3.5 mmol/L (70 to 135 mg/dL) is recommended.</li> <li>• In patients with LDL-C &gt;1.8 mmol/L (&gt;70 mg/dL) despite a maximally tolerated statin dose who remain at high risk, further therapy to reduce LDL-C should be considered.</li> <li>• ACE inhibitors are indicated starting within the first 24 hours of STEMI in patients with evidence of heart failure, LV systolic dysfunction, diabetes or an anterior infarct.</li> <li>• An ARB, preferably valsartan, is an alternative to ACE inhibitors in patients with heart failure or LV systolic dysfunction, particularly those who are intolerant to ACE inhibitors.</li> <li>• ACE inhibitors should be considered in all patients in the absence of contraindications.</li> <li>• Aldosterone antagonists, e.g. eplerenone, are indicated in patients with an ejection fraction ≤40% and heart failure or diabetes, provided no renal failure or hyperkalemia.</li> </ul>
American College of	<u>Top 10 messages for the primary prevention of cardiovascular disease</u>

Clinical Guideline	Recommendations
<p>Cardiology/ American Heart Association: <b>Guideline on the Primary Prevention of Cardiovascular Disease (2019)</b><sup>29</sup></p>	<ul style="list-style-type: none"> <li>• The most important way to prevent atherosclerotic vascular disease, heart failure, and atrial fibrillation is to promote a healthy lifestyle throughout life.</li> <li>• A team-based care approach is an effective strategy for the prevention of cardiovascular disease. Clinicians should evaluate the social determinants of health that affect individuals to inform treatment decisions.</li> <li>• Adults who are 40 to 75 years of age and are being evaluated for cardiovascular disease prevention should undergo 10-year atherosclerotic cardiovascular disease (ASCVD) risk estimation and have a clinician–patient risk discussion before starting on pharmacological therapy, such as antihypertensive therapy, a statin, or aspirin. In addition, assessing for other risk-enhancing factors can help guide decisions about preventive interventions in select individuals, as can coronary artery calcium scanning.</li> <li>• All adults should consume a healthy diet that emphasizes the intake of vegetables, fruits, nuts, whole grains, lean vegetable or animal protein, and fish and minimizes the intake of trans fats, processed meats, refined carbohydrates, and sweetened beverages. For adults with overweight and obesity, counseling and caloric restriction are recommended for achieving and maintaining weight loss.</li> <li>• Adults should engage in at least 150 minutes per week of accumulated moderate-intensity physical activity or 75 minutes per week of vigorous-intensity physical activity.</li> <li>• For adults with type 2 diabetes mellitus, lifestyle changes, such as improving dietary habits and achieving exercise recommendations, are crucial. If medication is indicated, metformin is first-line therapy, followed by consideration of a sodium-glucose cotransporter 2 inhibitor or a glucagon-like peptide-1 receptor agonist.</li> <li>• All adults should be assessed at every healthcare visit for tobacco use, and those who use tobacco should be assisted and strongly advised to quit.</li> <li>• Aspirin should be used infrequently in the routine primary prevention of ASCVD because of lack of net benefit.</li> <li>• Statin therapy is first-line treatment for primary prevention of ASCVD in patients with elevated low-density lipoprotein cholesterol levels (<math>\geq 190</math> mg/dL), those with diabetes mellitus, who are 40 to 75 years of age, and those determined to be at sufficient ASCVD risk after a clinician–patient risk discussion.</li> <li>• Nonpharmacological interventions are recommended for all adults with elevated blood pressure or hypertension. For those requiring pharmacological therapy, the target blood pressure should generally be <math>&lt;130/80</math> mm Hg.</li> </ul> <p><u>Adults with Type 2 Diabetes Mellitus</u></p> <ul style="list-style-type: none"> <li>• For all adults with T2DM, a tailored nutrition plan focusing on a heart-healthy dietary pattern is recommended to improve glycemic control, achieve weight loss if needed, and improve other ASCVD risk factors.</li> <li>• Adults with T2DM should perform at least 150 minutes per week of moderate-intensity physical activity or 75 minutes of vigorous-intensity physical activity to improve glycemic control, achieve weight loss if needed, and improve other ASCVD risk factors.</li> <li>• For adults with T2DM, it is reasonable to initiate metformin as first-line therapy along with lifestyle therapies at the time of diagnosis to improve glycemic control and reduce ASCVD risk.</li> <li>• For adults with T2DM and additional ASCVD risk factors who require glucose-lowering therapy despite initial lifestyle modifications and metformin, it may be reasonable to initiate a sodium-glucose cotransporter 2 (SGLT-2) inhibitor or a glucagon-like peptide-1 receptor (GLP-1R) agonist to improve glycemic control and reduce CVD risk.</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Adults with high blood cholesterol</u></p> <ul style="list-style-type: none"> <li>• In adults at intermediate risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk), statin therapy reduces risk of ASCVD, and in the context of a risk discussion, if a decision is made for statin therapy, a moderate-intensity statin should be recommended.</li> <li>• In intermediate risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk) patients, LDL-C levels should be reduced by 30% or more, and for optimal ASCVD risk reduction, especially in patients at high risk (<math>\geq 20\%</math> 10-year ASCVD risk), levels should be reduced by 50% or more.</li> <li>• In adults 40 to 75 years of age with diabetes, regardless of estimated 10-year ASCVD risk, moderate-intensity statin therapy is indicated.</li> <li>• In patients 20 to 75 years of age with an LDL-C level of 190 mg/dL (<math>\geq 4.9</math> mmol/L) or higher, maximally tolerated statin therapy is recommended.</li> <li>• In adults with diabetes mellitus who have multiple ASCVD risk factors, it is reasonable to prescribe high-intensity statin therapy with the aim to reduce LDL-C levels by 50% or more.</li> <li>• In intermediate-risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk) adults, risk-enhancing factors favor initiation or intensification of statin therapy.</li> <li>• In intermediate-risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk) adults or selected borderline-risk (5% to <math>&lt; 7.5\%</math> 10-year ASCVD risk) adults in whom a coronary artery calcium score is measured for the purpose of making a treatment decision, AND <ul style="list-style-type: none"> <li>○ If the coronary artery calcium score is zero, it is reasonable to withhold statin therapy and reassess in five to 10 years, as long as higher-risk conditions are absent (e.g., diabetes, family history of premature CHD, cigarette smoking);</li> <li>○ If coronary artery calcium score is one to 99, it is reasonable to initiate statin therapy for patients <math>\geq 55</math> years of age;</li> <li>○ If coronary artery calcium score is 100 or higher or in the 75th percentile or higher, it is reasonable to initiate statin therapy.</li> </ul> </li> <li>• In patients at borderline risk (5% to <math>&lt; 7.5\%</math> 10-year ASCVD risk), in risk discussion, the presence of risk-enhancing factors may justify initiation of moderate-intensity statin therapy.</li> </ul> <p><u>Adults with high blood pressure or hypertension</u></p> <ul style="list-style-type: none"> <li>• In adults with elevated blood pressure (BP) or hypertension, including those requiring antihypertensive medications nonpharmacological interventions are recommended to reduce BP. These include: <ul style="list-style-type: none"> <li>○ weight loss;</li> <li>○ a heart-healthy dietary pattern;</li> <li>○ sodium reduction;</li> <li>○ dietary potassium supplementation;</li> <li>○ increased physical activity with a structured exercise program; and</li> <li>○ limited alcohol.</li> </ul> </li> <li>• In adults with an estimated 10-year ASCVD risk (ACC/AHA pooled cohort equations to estimate 10-year risk of ASCVD) of 10% or higher and an average systolic BP (SBP) of 130 mm Hg or higher or an average diastolic BP (DBP) of 80 mm Hg or higher, use of BP-lowering medications is recommended for primary prevention of CVD.</li> <li>• In adults with confirmed hypertension and a 10-year ASCVD event risk of 10% or higher, a BP target of less than 130/80 mm Hg is recommended.</li> <li>• In adults with hypertension and chronic kidney disease, treatment to a BP goal of less than 130/80 mm Hg is recommended.</li> <li>• In adults with T2DM and hypertension, antihypertensive drug treatment should be initiated at a BP of 130/80 mm Hg or higher, with a treatment goal of less than</li> </ul>

Clinical Guideline	Recommendations
	<p>130/80 mm Hg.</p> <ul style="list-style-type: none"> <li>In adults with an estimated 10-year ASCVD risk &lt;10% and an SBP of 140 mm Hg or higher or a DBP of 90 mm Hg or higher, initiation and use of BP-lowering medication are recommended.</li> <li>In adults with confirmed hypertension without additional markers of increased ASCVD risk, a BP target of less than 130/80 mm Hg may be reasonable.</li> </ul> <p><u>Recommendations for treatment of tobacco use</u></p> <ul style="list-style-type: none"> <li>All adults should be assessed at every healthcare visit for tobacco use and their tobacco use status recorded as a vital sign to facilitate tobacco cessation.</li> <li>To achieve tobacco abstinence, all adults who use tobacco should be firmly advised to quit.</li> <li>In adults who use tobacco, a combination of behavioral interventions plus pharmacotherapy is recommended to maximize quit rates.</li> <li>In adults who use tobacco, tobacco abstinence is recommended to reduce ASCVD risk.</li> <li>To facilitate tobacco cessation, it is reasonable to dedicate trained staff to tobacco treatment in every healthcare system.</li> <li>All adults and adolescents should avoid secondhand smoke exposure to reduce ASCVD risk.</li> </ul> <p><u>Recommendations for aspirin use</u></p> <ul style="list-style-type: none"> <li>Low-dose aspirin (75 to 100 mg orally daily) might be considered for the primary prevention of ASCVD among select adults 40 to 70 years of age who are at higher ASCVD risk but not at increased bleeding risk.</li> <li>Low-dose aspirin (75 to 100 mg orally daily) should not be administered on a routine basis for the primary prevention of ASCVD among adults &gt;70 years of age.</li> <li>Low-dose aspirin (75 to 100 mg orally daily) should not be administered for the primary prevention of ASCVD among adults of any age who are at increased risk of bleeding.</li> </ul>
<p>American Heart Association/American College of Cardiology/Heart Failure Society of America: 2022 AHA/ACC/HFSA Guideline for the Management of Heart Failure (2022)<sup>30</sup></p>	<p><u>Treatment of Stage A heart failure (HF)</u></p> <ul style="list-style-type: none"> <li>Hypertension should be controlled in accordance with guideline-directed medication therapy for hypertension to prevent symptomatic HF. (LoE: A)</li> <li>In patients with type 2 diabetes and either established CVD or at high cardiovascular risk, SGLT-2 inhibitors should be used to prevent hospitalizations for HF. (LoE: A)</li> <li>In the general population, healthy lifestyle habits such as regular physical activity, maintaining normal weight, healthy dietary patterns, and avoiding smoking are helpful to reduce future risk of HF. (LoE: B)</li> <li>Patients at risk of developing HF, natriuretic peptide biomarker-based screening followed by team-based care, including a cardiovascular specialist optimizing therapy, can be useful to prevent the development of LV dysfunction (systolic or diastolic) or new-onset HF. (LoE: B)</li> </ul> <p><u>Treatment of Stage B heart failure</u></p> <ul style="list-style-type: none"> <li>In patients with LVEF≤40%, ACE inhibitors should be used to prevent HF and reduce mortality. (LoE: A)</li> <li>In patients with a recent or remote history of MI or ACS, statins should be used to prevent symptomatic HF and adverse cardiovascular events. (LoE: A)</li> <li>In patients with a recent MI and LVEF≤40% who are intolerant to ACE inhibitors, ARB should be used to prevent symptomatic HF and reduce mortality. (LoE: B)</li> <li>In patients with a recent or remote history of MI or ACS and LVEF≤40%,</li> </ul>

Clinical Guideline	Recommendations
	<p>evidence-based beta blockers should be used to reduce mortality. (LoE: B)</p> <ul style="list-style-type: none"> <li>• In patients who are at least 40 days post-MI with LVEF <math>\leq 30\%</math> and NYHA class I symptoms while receiving guideline-directed medication therapy and have reasonable expectation of meaningful survival for greater than one year, an implantable cardioverter-defibrillator is recommended for primary prevention of sudden cardiac death to reduce total mortality. (LoE: B)</li> <li>• In patients with LVEF <math>\leq 40\%</math>, beta blockers should be used to prevent symptomatic HF. (LoE: C)</li> <li>• In patients with LVEF <math>\leq 50\%</math>, thiazolidinediones should not be used because they increase the risk of HF, including hospitalizations. (LoE: B)</li> <li>• In patients with LVEF <math>\leq 50\%</math>, nondihydropyridine calcium channel blockers with negative inotropic effects may be harmful. (LoE: C)</li> </ul> <p><b>Treatment for Stage C Heart Failure with Reduced Ejection Fraction (HFrEF)</b></p> <ul style="list-style-type: none"> <li>• For patients with stage C HF, avoiding excessive sodium intake is reasonable to reduce congestive symptoms. (LoE: C)</li> <li>• In patients with HF who have fluid retention, diuretics are recommended to relieve congestion, improve symptoms, and prevent worsening HF. (LoE: B)</li> <li>• For patients with HF and congestive symptoms, addition of a thiazide (e.g., metolazone) to treatment with a loop diuretic should be reserved for patients who do not respond to moderate or high dose loop diuretics to minimize electrolyte abnormalities. (LoE: B)</li> <li>• In patients with HFrEF and NYHA class II to III symptoms, the use of an ARNI is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, the use of an ACE inhibitor is beneficial to reduce morbidity and mortality when the use of an ARNI is not feasible. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, who are intolerant to an ACE inhibitor because of cough or angioedema, and when the use of an ARNI is not feasible, the use of an ARB is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with chronic symptomatic HFrEF NYHA class II or III who tolerate an ACE inhibitor or ARB, replacement by an ARNI is recommended to further reduce morbidity and mortality. (LoE: B)</li> <li>• ARNIs should not be administered concomitantly with ACE inhibitors or within 36 hours of the last dose of an ACE inhibitor. (LoE: B)</li> <li>• ARNI or ACE inhibitors should not be administered in patients with a history of angioedema. (LoE: C)</li> <li>• In patients with HFrEF, with current or previous symptoms, use of one of the three <math>\beta</math>-blockers proven to reduce mortality (e.g., bisoprolol, carvedilol, sustained-release metoprolol succinate) is recommended to reduce mortality and hospitalizations. (LoE: A)</li> <li>• In patients with HFrEF and NYHA class II to IV symptoms, a mineralocorticoid receptor antagonist (spironolactone or eplerenone) is recommended to reduce morbidity and mortality, if eGFR is <math>&gt;30</math> mL/min/1.73 m<sup>2</sup> and serum potassium is <math>&lt;5.0</math> mEq/L. Careful monitoring of potassium, renal function, and diuretic dosing should be performed at initiation and closely followed thereafter to minimize risk of hyperkalemia and renal insufficiency. (LoE: A)</li> <li>• In patients taking a mineralocorticoid receptor antagonist whose serum potassium cannot be maintained at <math>&lt;5.5</math> mEq/L, mineralocorticoid receptor antagonist should be discontinued to avoid life threatening hyperkalemia. (LoE: B)</li> <li>• In patients with symptomatic chronic HFrEF, SGLT-2 an inhibitor is recommended to reduce hospitalization for HF and cardiovascular mortality, irrespective of the presence of type 2 diabetes. (LoE: A)</li> <li>• The combination of hydralazine and isosorbide dinitrate is recommended to</li> </ul>

Clinical Guideline	Recommendations
	<p>improve symptoms and reduce morbidity and mortality for patients self-identified as African Americans with NYHA class III to IV HFrEF receiving optimal therapy. (LoE: A)</p> <ul style="list-style-type: none"> <li>• In patients with current or previous symptomatic HFrEF who cannot be given first-line agents, such as an ARNI, ACE inhibitor or ARB because of drug intolerance or renal insufficiency, a combination of hydralazine and isosorbide dinitrate might be considered to reduce morbidity and mortality. (LoE: C)</li> <li>• In patients with HF class II to IV symptoms, omega-3 polyunsaturated fatty acid supplementation may be reasonable to use as adjunctive therapy to reduce mortality and cardiovascular hospitalizations. (LoE: B)</li> <li>• In patients with chronic HFrEF without specific indication (e.g., venous thromboembolism, atrial fibrillation, a previous thromboembolic event, or a cardioembolic source, anticoagulation is not recommended. (LoE: B)</li> <li>• Dihydropyridine and non-dihydropyridine calcium channel blockers are not recommended for patients with HFrEF. (LoE: A)</li> <li>• In patients with HFrEF, vitamins, nutritional supplements, and hormonal therapy are not recommended other than to correct specific deficiencies. (LoE: B)</li> <li>• In patients with HFrEF, class IC antiarrhythmic medication and dronedarone may increase risk of mortality. (LoE: A)</li> <li>• In patients with HFrEF, thiazolidinediones increase the risk of worsening HF symptoms and hospitalizations. (LoE: A)</li> <li>• In patients with type 2 diabetes and high cardiovascular risk, the DPP-4 inhibitors, saxagliptin and alogliptin, increase the risk of HF hospitalization and should be avoided in patients with HF. (LoE: B)</li> <li>• In patients with HFrEF, nonsteroidal anti-inflammatory drugs worsen HF symptoms and should be avoided or withdrawn whenever possible. (LoE: B)</li> <li>• For patients with symptomatic (NYHA class II to III) stable chronic HFrEF (LVEF <math>\leq</math>35%) who are receiving guideline-directed medical therapy, including a maximally tolerated dose of a beta blocker, and who are in sinus rhythm with a heart rate of <math>\geq</math>70 beats per minute at rest, ivabradine can be beneficial to reduce HF hospitalizations and cardiovascular death. (LoE: B)</li> <li>• In patients with symptomatic HFrEF despite guideline-directed medical therapy or who are unable to tolerate guideline-directed medical therapy, digoxin might be considered to decrease hospitalizations for HF. (LoE: B)</li> <li>• In select high-risk patients with HFrEF and recent worsening of HF already on guideline-directed medical therapy, an oral soluble guanylate cyclase stimulator (vericiguat) may be considered to reduce HF hospitalization and cardiovascular death. (LoE: B)</li> </ul> <p><u>Pharmacological treatment for Stage C HF with mildly reduced EF and improved EF</u></p> <ul style="list-style-type: none"> <li>• In patients with HF with mildly reduced EF, SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• Among patients with current or previous symptomatic HF with mildly reduced EF (LVEF, 41 to 49%), use of evidence-based beta blockers for HFrEF, ARNI, ACE inhibitor or ARB, and mineralocorticoid receptor antagonists may be considered to reduce the risk of HF hospitalization and cardiovascular mortality, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• In patients with HF with improved EF after treatment, guideline-directed medical therapy should be continued to prevent relapse of HF and LV dysfunction, even in patients who may become asymptomatic. (LoE: B)</li> </ul> <p><u>Pharmacological treatment for Stage C HF with preserved EF (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• Patients with hypertension and HFpEF should have medication titrated to attain blood pressure targets in accordance with published clinical practice guidelines to</li> </ul>

Clinical Guideline	Recommendations
	<p>prevent morbidity. (LoE: C)</p> <ul style="list-style-type: none"> <li>• SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• In patients with HFpEF, the use of a mineralocorticoid receptor antagonist, ARB, or ARNI may be considered to decrease hospitalizations, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• Routine use of nitrates or phosphodiesterase-5 inhibitors to increase activity or quality of life in patients with HFpEF is ineffective. (LoE: B)</li> </ul> <p><u>Treatment of Stage D (advanced/refractory) HF</u></p> <ul style="list-style-type: none"> <li>• For patients with advanced HF and hyponatremia, the benefit of fluid restriction to reduce congestive symptoms is uncertain. (LoE: C)</li> <li>• Continuous intravenous inotropic support is reasonable as “bridge therapy” in patients with HF (Stage D) refractory to guideline-directed medical therapy and device therapy who are eligible for and awaiting mechanical circulatory support or cardiac transplantation. (LoE: B)</li> <li>• In select patients with HF Stage D, despite optimal guideline-directed medical therapy and device therapy who are ineligible for either mechanical circulatory support or cardiac transplantation, continuous intravenous inotropic support may be considered as palliative therapy for symptom control and improvement in functional status. (LoE: B)</li> <li>• Long-term use of either continuous or intermittent, intravenous inotropic agents, for reasons other than palliative care or as a bridge to advanced therapies, is potentially harmful. (LoE: B)</li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure (2021)</b><sup>31</sup></p>	<p><u>Pharmacological treatments indicated in patients with (NYHA Class II-IV) heart failure with reduced ejection fraction</u></p> <ul style="list-style-type: none"> <li>• An ACE inhibitor is recommended, in addition to a <math>\beta</math>-blocker, for symptomatic patients with HFrEF to reduce the risk of HF hospitalization and death.</li> <li>• A mineralocorticoid receptor antagonist (MRA) is recommended for patients with HFrEF, who remain symptomatic despite treatment with an ACE inhibitor and a <math>\beta</math>-blocker, to reduce the risk of HF hospitalization and death.</li> <li>• Dapagliflozin or empagliflozin are recommended for patients with HFrEF to reduce the risk of HF hospitalization and death. Dapagliflozin or empagliflozin are recommended, in addition to optimal medical therapy with an ACE-I/ARNI, a <math>\beta</math>-blocker and an MRA, for patients with HFrEF regardless of diabetes status.</li> <li>• Sacubitril-valsartan is recommended as a replacement for an ACE inhibitor to further reduce the risk of HF hospitalization and death in ambulatory patients with HFrEF who remain symptomatic despite optimal treatment with an ACE inhibitor, a <math>\beta</math>-blocker, and a mineralocorticoid receptor antagonist.</li> <li>• Diuretics are recommended in order to improve symptoms and exercise capacity in patients with signs and/or symptoms of congestion.</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization or cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm despite treatment with an evidence-based dose of <math>\beta</math>-blocker (or maximum tolerated dose below that), ACE inhibitor (or ARB), and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm who are unable to tolerate or have contraindications for a <math>\beta</math>-blocker. Patients should also receive an ACE inhibitor (or ARB) and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• An ARB is recommended to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients unable to tolerate an ACE inhibitor (patients should also receive a <math>\beta</math>-blocker and mineralocorticoid receptor antagonist).</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• An ARB may be considered to reduce the risk of HF hospitalization and death in patients who are symptomatic despite treatment with a <math>\beta</math>-blocker who are unable to tolerate a mineralocorticoid receptor antagonist.</li> <li>• Vericiguat may be considered in patients in NYHA class II-IV who have had worsening HF despite treatment with an ACE-I (or ARNI), a <math>\beta</math>-blocker and an MRA to reduce the risk of CV mortality or HF hospitalization.</li> <li>• Hydralazine and isosorbide dinitrate should be considered in self-identified black patients with LVEF <math>\leq 35\%</math> or with an LVEF <math>&lt; 45\%</math> combined with a dilated LV in NYHA Class III-IV despite treatment with an ACE-I a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist to reduce the risk of HF hospitalization and death.</li> <li>• Hydralazine and isosorbide dinitrate may be considered in symptomatic patients with HFrEF who can tolerate neither an ACE inhibitor nor an ARB (or they are contraindicated) to reduce the risk of death.</li> <li>• Digoxin is a treatment with less-certain benefits and may be considered in symptomatic patients in sinus rhythm despite treatment with an ACE inhibitor (or ARB), a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist, to reduce the risk of hospitalization (both all-cause and HF-hospitalizations).</li> </ul> <p><u>Recommendations for treatment of patients with (NYHA class II-IV) heart failure with mildly reduced ejection fraction (HFmrEF)</u></p> <ul style="list-style-type: none"> <li>• Diuretics are recommended in patients with congestion and HFmrEF in order to alleviate symptoms and signs.</li> <li>• An ACE inhibitor may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An ARB may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• A <math>\beta</math>-blocker may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An MRA may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• Sacubitril/valsartan may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> </ul> <p><u>Recommendations for treatment of patients with heart failure with preserved ejection fraction (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• It is recommended to screen patients with HFpEF for both cardiovascular and noncardiovascular comorbidities, which, if present, should be treated provided safe and effective interventions exist to improve symptoms, well-being and/or prognosis.</li> <li>• Diuretics are recommended in congested patients with HFpEF in order to alleviate symptoms and signs.</li> </ul> <p><u>Recommendations for the primary prevention of heart failure in patients with risk factors for its development</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension is recommended to prevent or delay the onset of HF and prolong life.</li> <li>• Treatment with statins is recommended in patients at high risk of CV disease or with CV disease in order to prevent or delay the onset of HF, and to prevent HF hospitalizations.</li> <li>• SGLT2 inhibitors (canagliflozin, dapagliflozin, empagliflozin, ertugliflozin, sotagliflozin) are recommended in patients with diabetes at high risk of CV disease or with CV disease in order to prevent HF hospitalizations.</li> <li>• Counselling against sedentary habit, obesity, cigarette smoking, and alcohol abuse is recommended to prevent or delay the onset of HF.</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Recommendations for the initial management of patients with acute heart failure – pharmacotherapy</u></p> <ul style="list-style-type: none"> <li>• Intravenous loop diuretics are recommended for all patients with acute HF admitted with signs/symptoms of fluid overload to improve symptoms. It is recommended to regularly monitor symptoms, urine output, renal function and electrolytes during use of intravenous diuretics.</li> <li>• Combination of a loop diuretic with thiazide type diuretic should be considered in patients with resistant oedema who do not respond to an increase in loop diuretic doses.</li> <li>• In patients with acute HF and SBP &gt;110 mmHg, intravenous vasodilators may be considered as initial therapy to improve symptoms and reduce congestion.</li> <li>• Inotropic agents may be considered in patients with SBP &lt;90 mmHg and evidence of hypoperfusion who do not respond to standard treatment, including fluid challenge, to improve peripheral perfusion and maintain end-organ function.</li> <li>• Inotropic agents are not recommended routinely, due to safety concerns, unless the patient has symptomatic hypotension and evidence of hypoperfusion.</li> <li>• A vasopressor, preferably norepinephrine, may be considered in patients with cardiogenic shock to increase blood pressure and vital organ perfusion.</li> <li>• Thromboembolism prophylaxis (e.g. with LMWH) is recommended in patients not already anticoagulated and with no contraindication to anticoagulation, to reduce the risk of deep venous thrombosis and pulmonary embolism.</li> <li>• Routine use of opiates is not recommended, unless in selected patients with severe/intractable pain or anxiety.</li> </ul>
<p>Eighth Joint National Committee (JNC 8): <b>2014 Evidence-based Guideline for the Management of High Blood Pressure in Adults</b> (2014)<sup>32</sup></p>	<ul style="list-style-type: none"> <li>• Pharmacologic treatment should be initiated in patients ≥60 years of age to lower blood pressure at systolic blood pressure ≥150 mm Hg or diastolic blood pressure ≥90 mm Hg and to a goal systolic blood pressure &lt;150 mm Hg and goal diastolic blood pressure &lt;90 mm Hg. Adjustment of treatment is not necessary if treatment results in lower blood pressure and treatment is well tolerated and without adverse effects on health or quality of life.</li> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at diastolic blood pressure ≥90 mm Hg to a goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥150 mm Hg to a goal diastolic blood pressure &lt;140 mm Hg.</li> <li>• For patients ≥18 years of age with chronic kidney disease or diabetes, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥140 mm Hg or diastolic blood pressure ≥90 mm Hg and to a goal systolic blood pressure &lt;140 mm Hg and goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• Initial antihypertensive treatment for the general nonblack population, including those with diabetes, should include thiazide-type diuretic, calcium channel blocker (CCB), ACE inhibitor, or ARB.</li> <li>• Initial antihypertensive treatment for the general black population, including those with diabetes, should include thiazide-type diuretic or CCB.</li> <li>• For patients ≥18 years of age with chronic kidney disease regardless of race or diabetes status, initial (or add-on) treatment should include an ACE inhibitor or ARB to improve kidney outcomes.</li> <li>• The main goal of antihypertensive treatment is to attain and maintain goal blood pressure.</li> <li>• If goal blood pressure is not attained within a month of treatment, the dose of the initial drug should be increased or second drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• If goal is not achieved with two drugs, a third drug from the thiazide-type</li> </ul>

Clinical Guideline	Recommendations
	<p>diuretic, CCB, ACE inhibitor, or ARB classes should be added.</p> <ul style="list-style-type: none"> <li>• An ACE inhibitor and ARB should not be used together.</li> <li>• Antihypertensive classes can be used if the patient is unable to achieve goal blood pressure with three agents or had a contraindication to a preferred class.</li> <li>• If blood pressure is not able to be achieved or in complicated patients, referral to a hypertension specialist may be indicated.</li> </ul>
<p>International Society of Hypertension: <b>Global Hypertension Practice Guidelines (2020)</b><sup>33</sup></p>	<p><u>Lifestyle modifications</u></p> <ul style="list-style-type: none"> <li>• Lifestyle modification is the first line of antihypertensive treatment.</li> <li>• Salt reduction: Reduce salt added when preparing foods, and at the table. Avoid or limit consumption of high salt foods such as soy sauce, fast foods and processed food including breads and cereals high in salt.</li> <li>• Healthy diet: Eating a diet that is rich in whole grains, fruits, vegetables, polyunsaturated fats and dairy products and reducing food high in sugar, saturated fat and trans fats, such as the DASH diet.</li> <li>• Healthy drinks: Moderate consumption of coffee, green and black tea. Other beverages that can be beneficial include karkadé (hibiscus) tea, pomegranate juice, beetroot juice and cocoa.</li> <li>• Moderation of alcohol consumption: The recommended daily limit for alcohol consumption is 2 standard drinks for men and 1.5 for women (10 g alcohol/standard drink). Avoid binge drinking.</li> <li>• Weight reduction: Body weight control is indicated to avoid obesity. Particularly abdominal obesity should be managed. Ethnic-specific cut-offs for BMI and waist circumference should be used. Alternatively, a waist-to-height ratio &lt;0.5 is recommended for all populations.</li> <li>• Smoking cessation: Smoking is a major risk factor for cardiovascular disease (CVD), COPD and cancer. Smoking cessation and referral to smoking cessation programs are advised.</li> <li>• Regular physical activity: Studies suggest that regular aerobic and resistance exercise may be beneficial for both the prevention and treatment of hypertension. Moderate intensity aerobic exercise (walking, jogging, cycling, yoga, or swimming) for 30 minutes on five to seven days per week. Strength training also can help reduce blood pressure. Performance of resistance/strength exercises on two to three days per week.</li> <li>• Reduce stress and induce mindfulness: Stress should be reduced and mindfulness or meditation introduced into the daily routine.</li> <li>• Reduce exposure to air pollution and cold temperature: Evidence from studies support a negative effect of air pollution on blood pressure in the long-term.</li> </ul> <p><u>Pharmacological Treatment</u></p> <ul style="list-style-type: none"> <li>• Ideal characteristics of drug treatment <ul style="list-style-type: none"> <li>○ Treatments should be evidence-based in relation to morbidity/mortality prevention.</li> <li>○ Use a once-daily regimen which provides 24-hour blood pressure control.</li> <li>○ Treatment should be affordable and/or cost-effective relative to other agents.</li> <li>○ Treatments should be well-tolerated.</li> <li>○ Evidence of benefits of use of the medication in populations to which it is to be applied.</li> </ul> </li> <li>• General scheme for drug treatment <ul style="list-style-type: none"> <li>○ Lifestyle modification is the first line of antihypertensive treatment.</li> <li>○ Grade 1 hypertension (BP 140 to 159/ 90 to 99): Immediate drug treatment in high-risk patients or those with CVD, chronic kidney disease (CKD), diabetes mellitus (DM), or hypertension-mediated organ damage (HMOD). Drug treatment after three to six months of lifestyle intervention if BP still not controlled in low to moderate risk patients.</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>○ Grade 2 hypertension (BP <math>\geq</math>160/100): Immediate drug treatment in all patients.</li> <li>● Core drug-treatment strategy               <ul style="list-style-type: none"> <li>○ Step 1: Dual low-dose combination (ACE inhibitor or ARB plus dihydropyridine-calcium channel blockers (DHP-CCB)); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance; consider ACE/ARB plus DHP-CCB or DHP-CCB plus thiazide-like diuretics in black patients.</li> <li>○ Step 2: Dual full-dose combination (ACE inhibitor or ARB plus DHP-CCB); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance.</li> <li>○ Step 3: Triple combination (ACE/ARB plus DHP-CCB plus thiazide-like diuretic).</li> <li>○ Step 4, resistant hypertension: triple combination plus spironolactone or other drug, alternatives include amiloride, doxazosin, eplerenone, clonidine, or <math>\beta</math>-blocker. Caution with spironolactone or other potassium sparing diuretics when estimated GFR <math>&lt;</math>45 mL/min/1.73m<sup>2</sup> or K<sup>+</sup> <math>&gt;</math>4.5 mmol/L.</li> <li>○ Consider <math>\beta</math>-blockers at any treatment step when there is a specific indications for their use, e.g., heart failure, angina, post-MI, atrial fibrillation, or younger women planning pregnancy or pregnant.</li> </ul> </li> </ul>
<p>Hypertension Canada: 2020 Guidelines for the Prevention, Diagnosis, Risk Assessment, and Treatment of Hypertension in Adults and Children (2020)<sup>34</sup></p>	<p><u>Indications for drug therapy for adults with hypertension without compelling indications for specific agents</u></p> <ul style="list-style-type: none"> <li>● Antihypertensive therapy should be prescribed for average diastolic blood pressure (DBP) measurements of <math>\geq</math>100 mmHg or average systolic blood pressure (SBP) measurements of <math>\geq</math>160 mmHg in patients without macrovascular target organ damage or other cardiovascular risk factors.</li> <li>● Antihypertensive therapy should be strongly considered for average DPB readings <math>\geq</math>90 mmHg or for average SBP readings <math>\geq</math>140 mmHg in the presence of macrovascular target organ damage or other independent cardiovascular risk factors.</li> <li>● For high-risk patients, aged 50 years or older, with SBP levels <math>\geq</math>130 mmHg, intensive management to target a SBP <math>&lt;</math>120 mmHg should be considered. Patient selection for intensive management is recommended and caution should be taken in certain high-risk groups.</li> </ul> <p><u>Indications for drug therapy for adults with diastolic and with or without systolic hypertension</u></p> <ul style="list-style-type: none"> <li>● Initial therapy should be with either monotherapy or single pill combination (SPC).           <ul style="list-style-type: none"> <li>○ Recommended monotherapy choices are:               <ul style="list-style-type: none"> <li>▪ A thiazide/thiazide-like diuretic, with longer-acting diuretics preferred;</li> <li>▪ A <math>\beta</math>-blocker (in patients <math>&lt;</math>60 years of age);</li> <li>▪ An angiotensin-converting enzyme (ACE) inhibitor (in nonblack patients);</li> <li>▪ An angiotensin receptor blocker (ARB); or</li> <li>▪ A long-acting calcium channel blocker (CCB).</li> </ul> </li> <li>○ Recommended SPC choices are those in which an ACE inhibitor is combined with a CCB, ARB with a CCB, or ACE inhibitor or ARB with a diuretic.</li> <li>○ Hypokalemia should be avoided in patients treated with thiazide/thiazide-</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>like diuretic monotherapy.</p> <ul style="list-style-type: none"> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line choices. Useful choices include a thiazide/thiazide-like diuretic or CCB with either: ACE inhibitor, ARB, or <math>\beta</math>-blocker. Caution should be exercised in combining a nondihydropyridine CCB and a <math>\beta</math>-blocker. The combination of an ACE inhibitor and an ARB is not recommended.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other antihypertensive drugs may be added.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated hypertension; <math>\beta</math>-blockers are not recommended as first-line therapy for uncomplicated hypertension in patients <math>\geq 60</math> years of age; and ACE inhibitors are not recommended as first-line therapy for uncomplicated hypertension in black patients. However, these agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Indications for drug therapy for adults with isolated systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be single-agent therapy with a thiazide/thiazide-like diuretic, a long-acting dihydropyridine CCB, or an ARB. If there are adverse effects, another drug from this group should be substituted. Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line options.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other classes of drugs (such as <math>\alpha</math>-blockers, ACE inhibitors, centrally acting agents, or nondihydropyridine CCBs) may be combined or substituted.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated isolated systolic hypertension; and <math>\beta</math>-blockers are not recommended as first-line therapy for isolated systolic hypertension in patients <math>\geq 60</math> years of age. However, both agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Guidelines for hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• For most hypertensive patients with CAD, an ACE inhibitor or ARB is recommended.</li> <li>• For hypertensive patients with CAD, but without coexisting systolic heart failure, the combination of an ACE inhibitor and ARB is not recommended.</li> <li>• For high-risk hypertensive patients, when combination therapy is being used, choices should be individualized. The combination of an ACE inhibitor and a dihydropyridine CCB is preferable to an ACE inhibitor and a thiazide/thiazide-like diuretic in selected patients.</li> <li>• For patients with stable angina pectoris but without previous heart failure, myocardial infarction, or coronary artery bypass surgery, either a <math>\beta</math>-blocker or CCB can be used as initial therapy.</li> <li>• Short-acting nifedipine should not be used.</li> <li>• When decreasing SBP to target levels in patients with established CAD (especially if isolated systolic hypertension is present), be cautious when the DBP is <math>\leq 60</math> mmHg because of concerns that myocardial ischemia might be exacerbated, especially in patients with left ventricular hypertrophy (LVH).</li> </ul> <p><u>Guidelines for patients with hypertension who have had a recent myocardial</u></p>

Clinical Guideline	Recommendations
	<p><b>infarction</b></p> <ul style="list-style-type: none"> <li>• Initial therapy should include a <math>\beta</math>-blocker as well as an ACE inhibitor.</li> <li>• An ARB can be used if the patient is intolerant of an ACE inhibitor.</li> <li>• CCBs may be used in patients after myocardial infarction when <math>\beta</math>-blockers are contraindicated or not effective. Nondihydropyridine CCBs should not be used when there is heart failure, evidenced by pulmonary congestion on examination or radiography.</li> </ul> <p><b>Treatment of hypertension in association with heart failure</b></p> <ul style="list-style-type: none"> <li>• In patients with systolic dysfunction (ejection fraction &lt;40%), ACE inhibitors and <math>\beta</math>-blockers are recommended for initial therapy. Aldosterone antagonists (mineralocorticoid receptor antagonists) may be combined in treatment for patients with a recent cardiovascular hospitalization, acute myocardial infarction, elevated B-type natriuretic peptide or N-terminal pro-B-type natriuretic peptide level, or New York Heart Association (NYHA) Class II-IV symptoms. Careful monitoring for hyperkalemia is recommended when combining an aldosterone antagonist with ACE inhibitor or ARB treatment. Other diuretics are recommended as additional therapy if needed. Beyond considerations of BP control, doses of ACE inhibitors or ARBs should be titrated to those reported to be effective in trials unless adverse effects become manifest.</li> <li>• An ARB is recommended if ACE inhibitors are not tolerated.</li> <li>• A combination of hydralazine and isosorbide dinitrate is recommended if ACE inhibitors and ARBs are contraindicated or not tolerated.</li> <li>• For hypertensive patients whose BP is not controlled, an ARB may be combined with an ACE inhibitor and other antihypertensive drug treatment. Careful monitoring should be used if combining an ACE inhibitor and an ARB because of potential adverse effects such as hypotension, hyperkalemia, and worsening renal function. Additional therapies may also include dihydropyridine CCBs.</li> <li>• An angiotensin receptor-neprilysin inhibitor (ARNI) should be used in place of an ACE inhibitor or ARB for patients with HFrEF (&lt;40%) who remain symptomatic despite treatment with appropriate dose of guideline directed HF therapy. Eligible patients must have a serum potassium &lt;5.2 mmol/L, an eGFR <math>\leq 30</math> mL/min/1.73m<sup>2</sup> and close surveillance of serum potassium and creatinine.</li> </ul> <p><b>Treatment of hypertension in association with stroke</b></p> <ul style="list-style-type: none"> <li>• BP management in acute ischemic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> <li>• BP management after acute ischemic stroke <ul style="list-style-type: none"> <li>○ Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack.</li> <li>○ After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently &lt;140/90 mmHg.</li> <li>○ Treatment with an ACE inhibitor and thiazide/thiazide-like diuretic combination is preferred.</li> <li>○ For patients with stroke, the combination of an ACE inhibitor and ARB is not recommended.</li> </ul> </li> <li>• BP management in hemorrhagic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> </ul> <p><b>Treatment of hypertension in association with LVH</b></p> <ul style="list-style-type: none"> <li>• Hypertensive patients with LVH should be treated with antihypertensive therapy to decrease the rate of subsequent cardiovascular events.</li> <li>• The choice of initial therapy can be influenced by the presence of LVH. Initial therapy can be drug treatment using ACE inhibitors, ARBs, long-acting CCBs, or thiazide/thiazide-like diuretics. Direct arterial vasodilators such as hydralazine or</li> </ul>

Clinical Guideline	Recommendations
	<p><b>minoxidil should not be used.</b></p> <p><b>Treatment of hypertension in association with nondiabetic chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>Individualize BP targets in patients with chronic kidney disease. Consider intensive targets (SBP &lt;120 mmHg) in appropriate patients.</li> <li>For patients with hypertension and proteinuric chronic kidney disease (urinary protein &gt;150 mg per 24 hours or albumin to creatinine ratio &gt;30 mg/mmol), initial therapy should be an ACE inhibitor or an ARB if there is intolerance to ACE inhibitors.</li> <li>In most cases, combination therapy with other antihypertensive agents might be needed to reach target BP levels.</li> <li>The combination of an ACE inhibitor and ARB is not recommended for patients with nonproteinuric chronic kidney disease.</li> </ul> <p><b>Treatment of hypertension in association with renovascular disease</b></p> <ul style="list-style-type: none"> <li>Patients with hypertension attributable to atherosclerotic renal artery stenosis should be primarily medically managed because renal angioplasty and stenting offers no benefit over optimal medical therapy alone.</li> <li>Renal artery angioplasty and stenting for atherosclerotic hemodynamically significant renal artery stenosis could be considered for patients with uncontrolled hypertension resistant to maximally tolerated pharmacotherapy, progressive renal function loss, and acute pulmonary edema.</li> <li>Patients with confirmed renal fibromuscular dysplasia (FMD) should be referred to a hypertension specialist.</li> <li>Renal artery angioplasty without stenting is recommended for treatment of FMD-related renal artery stenosis. Stenting is not recommended unless needed because of a periprocedural dissection. Surgical revascularization should be considered in cases of complex lesions less amenable to angioplasty, stenosis associated with complex aneurysm, and restenosis despite two unsuccessful attempts of angioplasty.</li> </ul> <p><b>Treatment of hypertension in association with diabetes mellitus</b></p> <ul style="list-style-type: none"> <li>Persons with diabetes mellitus should be treated to attain SBP of &lt;130 mmHg and DBP of &lt;80 mmHg.</li> <li>For persons with cardiovascular or kidney disease, including microalbuminuria, or with cardiovascular risk factors in addition to diabetes and hypertension, an ACE inhibitor or an ARB is recommended as initial therapy.</li> <li>For persons with diabetes and hypertension not included in other guidelines in this section, appropriate choices include (in alphabetical order): ACE inhibitors, ARBs, dihydropyridine CCBs, and thiazide/thiazide-like diuretics.</li> <li>If target BP levels are not achieved with standard-dose monotherapy, additional antihypertensive therapy should be used. For persons in whom combination therapy with an ACE inhibitor is being considered, a dihydropyridine CCB is preferable to a thiazide/thiazide-like diuretic.</li> </ul> <p><b>Resistant hypertension</b></p> <ul style="list-style-type: none"> <li>Resistant hypertension is defined as BP above target despite three or more BP-lowering drugs at optimal doses preferably including a diuretic (and usually a renin-angiotensin-aldosterone system blocker and a CCB).</li> <li>Accurate office and out-of-office BP measurement is essential.</li> <li>Other reasons for apparent resistant hypertension should be eliminated before diagnosing true resistant hypertension, including nonadherence, white coat effect, and secondary hypertension.</li> <li>Pharmacotherapy with the additional use of spironolactone, bisoprolol, doxazosin, amiloride, eplerenone, or clonidine with the baseline regimen</li> </ul>

Clinical Guideline	Recommendations
	<p>decreases BP significantly, with the greatest BP-lowering shown with spironolactone.</p> <ul style="list-style-type: none"> <li>Patients with resistant hypertension should be referred to providers with expertise in diagnosis and management of hypertension.</li> </ul> <p><u>Hypertension and pediatrics</u></p> <ul style="list-style-type: none"> <li>BP should be measured regularly in children three years of age or older; the auscultatory method is the gold-standard at present.</li> <li>Initial therapy should be monotherapy, with an ACE inhibitor or ARB (not first-line in black children), or a long-acting dihydropyridine CCB.</li> <li>The treatment goal is systolic and diastolic office BP and/or ABPM &lt; 95th percentile or &lt;90th percentile in children with risk factors or target organ damage.</li> <li>Complex cases should be referred to an expert in pediatric hypertension.</li> </ul> <p><u>Hypertension and pregnancy</u></p> <ul style="list-style-type: none"> <li>Up to 7% of pregnancies are complicated by a hypertensive disorder of pregnancy, and approximately 5% of women will have chronic hypertension when they become pregnant.</li> <li>The prevalence of hypertension in pregnancy is expected to increase with women becoming pregnant later in their reproductive years and the increasing prevalence of cardiovascular comorbidities such as increased preconception body mass index and maternal diabetes.</li> <li>The possibility of pregnancy should be considered when managing women with hypertension who are of reproductive age.</li> <li>Preconception counselling should be offered to all women with hypertension who are considering pregnancy.</li> <li>ACE inhibitor and ARB therapy should be avoided before conception and during pregnancy unless there is a compelling indication for their use (i.e., proteinuric kidney disease).</li> <li>Hypertension during pregnancy can increase the risk of adverse maternal and fetal outcomes, including an increased risk of preeclampsia, placental abruption, prematurity, small for gestational age infants, stillbirth, and maternal renal and retinal injury, thus generally requires involvement of an interdisciplinary team including obstetrical care providers.</li> <li>Antihypertensive therapy is recommended for average SBP measurements of <math>\geq 140</math> mmHg or DBP measurements of <math>\geq 90</math> mmHg in pregnant women with chronic hypertension, gestational hypertension, or preeclampsia. Initial antihypertensive therapy should be monotherapy from the following first-line drugs: oral labetalol, oral methyldopa, long-acting oral nifedipine, or other oral <math>\beta</math>-blockers (acebutolol, metoprolol, pindolol, and propranolol). Other antihypertensive drugs can be considered as second-line drugs including: clonidine, hydralazine, and thiazide diuretics.</li> <li>Women with severe hypertension with SBP <math>\geq 160</math> mmHg or DBP <math>\geq 110</math> mmHg in pregnancy or postpartum require urgent antihypertensive therapy because it is considered an obstetrical emergency.</li> <li>Antihypertensive drugs used in breastfeeding women include: labetalol, methyldopa, long-acting nifedipine, enalapril, or captopril.</li> </ul>
<p>European Society of Hypertension/ European Society of Cardiology: <b>2018 Guidelines for the management of arterial hypertension (2018)</b><sup>35</sup></p>	<p><u>Treatment strategies and choice of antihypertensive drugs</u></p> <ul style="list-style-type: none"> <li>Diuretics (including thiazides, chlorthalidone, and indapamide), <math>\beta</math>-blockers, calcium channel blocker (CCB), angiotensin-converting enzyme (ACE) inhibitors, and angiotensin receptor blockers (ARBs) are all suitable for the initiation and maintenance of antihypertensive treatment, either as monotherapy or in some combinations.</li> <li>Some agents should be considered as the preferential choice in specific conditions because used in trials in those conditions or because of greater</li> </ul>

Clinical Guideline	Recommendations
	<p>effectiveness in specific types of organ damage. Preferred combinations should comprise a renin-angiotensin system (RAS) blocker (either an ACE inhibitor or an ARB) with a CCB or diuretic.</p> <ul style="list-style-type: none"> <li>• It is recommended that beta-blockers are combined with any of the other major drug classes when there are specific clinical situations, e.g. angina, post-myocardial infarction, heart failure, or heart rate control.</li> <li>• Initiation of antihypertensive therapy with a two-drug combination may be considered in patients with markedly high baseline blood pressure (BP) or at high cardiovascular (CV) risk.</li> <li>• The combination of two antagonists of the RAS is not recommended and should be discouraged.</li> <li>• Other drug combinations should be considered and probably are beneficial in proportion to the extent of BP reduction. However, combinations that have been successfully used in trials may be preferable.</li> <li>• Combinations of two antihypertensive drugs at fixed doses in a single tablet may be recommended and favored, because reducing the number of daily pills improves adherence, which is low in patients with hypertension. Exceptions are frail older patients and those at low risk and with grade one hypertension (particularly if systolic BP is &lt;150 mmHg).</li> <li>• It is recommended that if BP is not controlled with a three-drug combination, treatment should be increased by the addition of spironolactone or, if not tolerated, other diuretics such as amiloride or higher doses of other diuretics, a beta-blocker, or an alpha-blocker.</li> </ul> <p><u>Treatment strategies in white-coat and masked hypertension</u></p> <ul style="list-style-type: none"> <li>• In white-coat hypertensives without additional risk factors, therapeutic intervention may be limited to lifestyle changes only, but this decision should be accompanied by close follow-up.</li> <li>• In white-coat hypertensives with a higher CV risk or hypertension-mediated organ damage, drug treatment may be considered in addition to lifestyle changes.</li> <li>• In masked hypertension, both lifestyle measures and antihypertensive drug treatment should be considered, because this type of hypertension has been consistently found to have a CV risk very close to that of in- and out-of-office hypertension.</li> <li>• Antihypertensive drug up-titration should be considered in treated patients whose out-of-office BP is not controlled (i.e., masked uncontrolled hypertension), because of the high CV risk of these patients.</li> </ul> <p><u>Antihypertensive treatment strategies in the elderly</u></p> <ul style="list-style-type: none"> <li>• It is recommended that older patients (≥65 years) are treated with the same recommendations in non-older patient population. In very old patients (≥80 years), it may be appropriate to initiate treatment with monotherapy.</li> <li>• In all older patients, when combination therapy is used, it is recommended that this is initiated at the lowest available doses. In all older patients, and especially very old or frail patients, the possible occurrence of postural BP should be closely monitored and symptoms of possible hypotensive episodes checked by ambulatory blood pressure monitoring.</li> <li>• Unless required for concomitant diseases, loop diuretics and alpha-blockers should be avoided because of their association with injurious falls.</li> <li>• Renal function should be frequently assessed to detect possible increases in serum creatinine and reductions in estimated glomerular filtration rate (eGFR) as a result of BP-related reductions in renal perfusion.</li> <li>• When treated, BP should be lowered to a systolic value of 130 to 139 mmHg and a diastolic value of &lt;80 mmHg if tolerated. Treated values of &lt;130 mmHg should be avoided.</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Treatment strategies in hypertensive women</u></p> <ul style="list-style-type: none"> <li>• Hormone therapy and selective estrogen receptor modulators are not recommended and should not be used for primary or secondary prevention of CVD.</li> <li>• In women with gestational hypertension, pre-existing hypertension superimposed by gestational hypertension, or with hypertension and subclinical organ damage or symptoms, initiation of drug treatments is recommended when SBP is <math>\geq 140</math> mmHg or DBP <math>\geq 90</math> mmHg. In all other cases, initiation of drug treatment is recommended when SBP is <math>\geq 150</math> mmHg or DBP is <math>\geq 95</math> mmHg.</li> <li>• Methyldopa, labetalol, and CCBs are recommended as the drugs of choice for the treatment of hypertension in pregnancy.</li> <li>• ACE inhibitors, ARBs, or direct renin inhibitors are not recommended during pregnancy.</li> <li>• SBP <math>\geq 170</math> mmHg or DBP <math>\geq 110</math> mmHg in a pregnant woman is an emergency, and admission to hospital is recommended.</li> <li>• In severe hypertension, drug treatment with intravenous (IV) labetalol, oral methyldopa, or nifedipine is recommended.</li> <li>• The recommended treatment for hypertensive crisis is IV labetalol or nicardipine and magnesium.</li> <li>• In pre-eclampsia associated with pulmonary edema, nitroglycerin given as an IV infusion is recommended.</li> <li>• In women with gestational hypertension or mild-pre-eclampsia, delivery is recommended at 37 weeks.</li> <li>• It is recommended to expedite delivery in pre-eclampsia with adverse conditions, such as visual disturbances or hemostatic disorders</li> <li>• In women at high risk of pre-eclampsia, provided they are at low risk of gastrointestinal hemorrhage, treatment with low dose aspirin from 12 weeks until delivery may be considered.</li> <li>• Methyldopa, labetalol, and nifedipine should be considered preferential antihypertensive drugs in pregnancy. Intravenous labetalol or infusion of nitroprusside should be considered in case of emergency (pre-eclampsia).</li> </ul> <p><u>Treatment strategies in patients with diabetes</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive drug treatment is recommended for people with diabetes when office BP is <math>\geq 140/90</math> mmHg.</li> <li>• A SBP goal <math>&lt; 130</math> mmHg is recommended in patients with diabetes and <math>&lt; 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg.</li> <li>• In older people, the target SBP range is 130 to 139 mmHg.</li> <li>• The DBP target in patients with diabetes is recommended to be <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• It is recommended to initiate treatment with a combination of a RAS blocker with a CCB or thiazide/thiazide-like diuretic.</li> <li>• It is recommended that individual drug choice takes comorbidities into account.</li> <li>• Simultaneous administration of two blockers of the RAS is not recommended and should be avoided in patients with diabetes.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with nephropathy</u></p> <ul style="list-style-type: none"> <li>• In patients with diabetic and non-diabetic CKD, it is recommended that an office BP of <math>\geq 140/90</math> mmHg be treated with lifestyle advice and BP-lowering medication.</li> <li>• In patients with diabetic or non-diabetic CKD, it is recommended to lower SBP to a range of 130 to 139 mmHg. And individualized treatments should be considered according to its tolerability and impact on renal function and electrolytes.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• A combination of a RAS blocker with a CCB or a diuretic is recommended as initial therapy.</li> <li>• RAS blockers are more effective in reducing albuminuria than other antihypertensive agents, and are indicated in hypertensive patients in the presence of microalbuminuria or overt proteinuria.</li> <li>• Combination of two RAS blockers, though potentially more effective in reducing proteinuria, is not recommended.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with cerebrovascular disease</u></p> <ul style="list-style-type: none"> <li>• In patients with acute intracerebral hemorrhage, immediate BP lowering is not recommended for patients with SBP &lt;220 mmHg. In patients with SBP <math>\geq</math>220 mmHg, care acute BP lowering with IV therapy to &lt;180 mmHg should be considered.</li> <li>• In acute ischemic stroke, routine BP lowering with antihypertensive therapy is not recommended with the exceptions with the exceptions: in patients with acute ischemic stroke who are eligible for IV thrombolysis, BP should be carefully lowered and maintained at &lt;180/105 mmHg for at least the first 24 hours after thrombolysis; In patients with markedly elevated BP who do not receive fibrinolysis, drug therapy may be considered, based on clinical judgement, to reduce BP by 15% during the first 24 hours after the stroke onset.</li> <li>• In hypertensive patients with an acute cerebrovascular event, antihypertensive treatment is recommended immediately for transient ischemic attack (TIA) and after several days in ischemic stroke.</li> <li>• In all hypertensive patients with ischemic stroke or TIA, an SBP target range of 120 to 130 mmHg should be considered.</li> <li>• The recommended antihypertensive drug treatment strategy for stroke prevention is a RAS blocker plus a CCB or a thiazide-like diuretic.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with heart failure (HF) or left ventricular hypertrophy (LVH)</u></p> <ul style="list-style-type: none"> <li>• In hypertensive patients with heart failure (with reduced or preserved ejection fraction), BP-lowering treatment should be considered if <math>\geq</math>140/90 mmHg.</li> <li>• In patients with HF<sub>r</sub>EF, it is recommended that BP-lowering treatment comprises an ACE inhibitor or ARB, and a beta-blocker and a diuretic and/or mineralocorticoid receptor antagonist (MRA) if required.</li> <li>• Dihydropyridine CCBs may be added if BP control is not achieved.</li> <li>• In patients with HF<sub>p</sub>EF, BP treatment threshold and target values should be the same as for HF<sub>r</sub>EF).</li> <li>• Because no specific drug has proven its superiority, all major agents can be used.</li> <li>• In all patients with LVH, it is recommended to treat with a RAS blocker or in combination with a CCB or diuretic and SBP should be lowered to a range of 120 to 130 mmHg.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• In patients with CAD receiving BP-lowering drugs, it is recommended to target SBP to <math>\leq</math>130 mmHg if tolerated, but not &lt;120 mmHg. In older patients, the target is an SBP range of 130 to 140 mmHg. The target DBP is &lt;80 mmHg, but not &lt;70 mmHg.</li> <li>• In hypertensive patients with a history of myocardial infarction, beta-blockers and RAS blockers are recommended as part of treatment.</li> <li>• In patients with asymptomatic angina, beta-blockers and/or CCBs are recommended.</li> </ul>
National Institute for Health and Clinical	<u>Choosing antihypertensive drug treatment (for people with or without type II diabetes)</u>

Clinical Guideline	Recommendations
<p>Excellence: <b>Hypertension in adults: diagnosis and management (2019)</b><sup>36</sup></p>	<ul style="list-style-type: none"> <li>• Where possible, recommend treatment with drugs taken only once a day.</li> <li>• Prescribe non-proprietary drugs where these are appropriate and minimize cost.</li> <li>• Offer people with isolated systolic hypertension (systolic blood pressure <math>\geq 160</math> mmHg) the same treatment as people with both raised systolic and diastolic blood pressure.</li> <li>• Offer antihypertensive drug treatment to women of child-bearing potential with diagnosed hypertension in line with recommendations in this guideline. For women considering pregnancy or who are pregnant or breastfeeding, manage hypertension in line with the recommendations on Management of pregnancy with chronic hypertension and Breastfeeding in 'Hypertension in pregnancy'.</li> <li>• When choosing antihypertensive drug treatment for adults of black African or African-Caribbean family origin, consider an angiotensin II receptor blocker, in preference to an angiotensin-converting enzyme inhibitor.</li> </ul> <p><u>Step one treatment</u></p> <ul style="list-style-type: none"> <li>• Patients &lt;55 years of age should be offered a step one antihypertensive with an angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB).</li> <li>• Offer an ACE inhibitor or an ARB to adults starting step 1 antihypertensive treatment who have type II diabetes and are of any age or family origin or those aged &lt;55 years but not of black African or African-Caribbean family origin.</li> <li>• If an ACE inhibitor is not tolerated, offer an ARB.</li> <li>• Do not combine an ACE inhibitor with an ARB for the treatment of hypertension.</li> <li>• Offer a calcium channel blocker (CCB) to adults starting step 1 antihypertensive treatment who are &gt;55 years of age and do not have diabetes and are of black African or African-Caribbean family origin and do not have type II diabetes and of any age.</li> <li>• If a CCB is not suitable, for example because of edema or intolerance, or if there is evidence of heart failure or a high risk of heart failure, offer a thiazide-like diuretic.</li> <li>• If diuretic treatment is to be initiated or changed, offer a thiazide-like diuretic, such as indapamide in preference to a conventional thiazide diuretic such as bendroflumethiazide or hydrochlorothiazide.</li> <li>• For adults with hypertension who are already receiving treatment with bendroflumethiazide or hydrochlorothiazide, who have stable, well-controlled blood pressure, continue with their treatment.</li> </ul> <p><u>Step two treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering next step treatment for hypertension discuss with the person if they are taking their medicine as prescribed and support adherence in line with NICE's guideline on "Medicines adherence: involving patients decisions about prescribed medicines and supporting adherence".</li> <li>• If hypertension is not controlled with a step one treatment of an ACE inhibitor or ARB, offer choice of one of the following drugs in addition to the step one treatment: a CCB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults taking step one treatment of a CCB, offer the choice of one of the following drugs in addition to the step one treatment: an ACE inhibitor or an ARB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults of black African or African-Caribbean family origin who do not have type 2 diabetes taking step one treatment, consider an ARB, in preference to an ACE inhibitor, in addition to step one treatment.</li> </ul> <p><u>Step three treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering step three treatment, review the person's medications to</li> </ul>

Clinical Guideline	Recommendations
	<p>ensure they are being taken at the optimal doses and discuss adherence (see recommendation under step two).</p> <ul style="list-style-type: none"> <li>If hypertension is not controlled in adults taking step two treatment, offer a combination of an ACE inhibitor or ARB and a CCB and a thiazide-like diuretic.</li> </ul> <p><u>Step four treatment</u></p> <ul style="list-style-type: none"> <li>If hypertension is not controlled in adults taking the optimal tolerated doses of an ACE inhibitor or an ARB plus a CCB and a thiazide-like diuretic, regard them as having resistant hypertension.</li> <li>Before considering further treatment for a person with resistant hypertension, confirm elevated clinic blood pressure measurements using ambulatory or home blood pressure recordings, assess for postural hypotension, and discuss adherence.</li> <li>For people with confirmed resistant hypertension, consider adding a fourth antihypertensive drug as step four treatment or seeking specialist advice.</li> <li>Consider further diuretic therapy with low-dose spironolactone for adults with resistant hypertension starting step four treatment who have a blood potassium level of 4.5 mmol/l or less. Use particular caution in people with a reduced estimated glomerular filtration rate because they have an increased risk of hyperkalemia.</li> <li>When using further diuretic therapy for step four treatment of resistant hypertension, monitor blood sodium and potassium and renal function within one month of starting treatment and repeat as needed thereafter.</li> <li>Consider an alpha-blocker or beta-blocker for adults with resistant hypertension starting step four treatment who have a blood potassium level of more than 4.5 mmol/l.</li> <li>If blood pressure remains uncontrolled in people with resistant hypertension taking the optimal tolerated doses of four drugs, seek specialist advice.</li> </ul>
<p>International Society on Hypertension in Blacks: <b>Management of High Blood Pressure in Blacks (2010)</b><sup>37</sup></p>	<ul style="list-style-type: none"> <li>To attain and maintain blood pressure (BP) below target levels, multiple antihypertensive drugs will be required in most hypertensive blacks.</li> <li>Use of two-drug combination therapy when SBP is &gt;15 mm Hg and/or DBP is &gt;10 mm Hg above goal levels is increasingly recommended as first-line therapy.</li> <li>Two-drug regimens have generally contained a thiazide-type diuretic; however, the combination of a calcium channel blocker (CCB) with either an ACE inhibitor or an ARB has been shown equally efficacious in BP lowering but with demonstrated superiority (CCB+ACE) for hard clinical outcomes compared with the same ACE inhibitor plus a thiazide-type diuretic.</li> <li>In secondary prevention patients, the combination therapy should include a drug(s) with the appropriate compelling indications.</li> <li>Certain classes of antihypertensive medications, specifically diuretics and CCBs, lower BP on average more than <math>\beta</math>-blockers and renin-angiotensin system (RAS) blockers in black patients when used as monotherapies.</li> <li>In the absence of compelling indications, when BP is near goal levels, monotherapy with a diuretic or a CCB is preferred.</li> <li>Lifestyle modifications should be initiated in all patients with hypertension, whether or not pharmacotherapy is planned.</li> <li>ACE inhibitors or ARBs are recommended as alternative monotherapy options in the treatment of hypertension in blacks. The rationale for their lower tier monotherapy recommendation is because they have consistently achieved lesser average reductions in BP relative to that observed with monotherapy using either a diuretic or CCB.</li> </ul>
<p><b>Kidney Disease Improving Clinical Outcomes Group:</b></p>	<p><u>Blood pressure measurement</u></p> <ul style="list-style-type: none"> <li>The Work Group recommends standardized office blood pressure (BP) measurement in preference to routine office BP measurements for the</li> </ul>

<p>American College of Cardiology/ American Heart Association Task Force: <b>Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults</b> (2017)<sup>39</sup></p>	<p><u>Initiation of Blood Pressure (BP) Treatment for Overall Cardiovascular Disease (CVD) Risk</u></p> <ul style="list-style-type: none"> <li>Use of BP-lowering medications is recommended for secondary prevention of recurrent CVD events in patients with clinical CVD and an average systolic blood pressure (SBP) <math>\geq 130</math> mmHg or an average diastolic blood pressure (DBP) of <math>\geq 80</math> mmHg and for primary prevention in adults with an estimated 10-year atherosclerotic cardiovascular disease (ASCVD) risk of <math>\geq 10\%</math> and an average SBP of <math>\geq 130</math> mmHg or an average <math>\geq 80</math> mmHg.</li> <li>Use of BP-lowering medication is recommended for primary prevention of CVD in adults with no history of CVD and with an estimated 10-year ASCVD risk &lt;10% and an SBP of <math>\geq 140</math> mmHg or a DBP of <math>\geq 90</math> mmHg.</li> <li>Simultaneous use of an angiotensin converting enzyme (ACE) inhibitor,</li> </ul>

Clinical Guideline	Recommendations
	<p>angiotensin receptor blocker (ARB), and/or renin inhibitor is potentially harmful and is not recommended to treat adults with hypertension.</p> <ul style="list-style-type: none"> <li>• For adults with confirmed hypertension and known CVD or 10-year ASCVD risk of <math>\geq 10\%</math>, a BP target <math>&lt; 130/80</math> mmHg is recommended. For adults with confirmed hypertension without additional markers of increased CVD risk, a BP target <math>&lt; 130/80</math> mmHg may be reasonable.</li> <li>• For initiation of antihypertensive drug therapy, first-line agents include thiazide diuretics, calcium channel blockers (CCBs), and ACE inhibitors or ARBs.</li> <li>• Initiation of antihypertensive drug therapy with two first-line agents of different classes, either as separate agents or in a fixed-dose combination, is recommended in adults with stage 2 hypertension and an average BP <math>&gt; 20/10</math> mmHg above their BP target.</li> <li>• Initiation of antihypertensive drug therapy with a single antihypertensive drug is reasonable in adults with stage 1 hypertension and BP goal <math>&lt; 130/80</math> mmHg with dosage titration and sequential addition of other agents to achieve the BP target.</li> </ul> <p><u>Stable Ischemic Heart Disease (SIHD)</u></p> <ul style="list-style-type: none"> <li>• In adults with SIHD and hypertension, a BP target <math>&lt; 130/80</math> is recommended.</li> <li>• Adults with SIHD and hypertension (BP <math>\geq 130/80</math> mmHg) should be treated with medications [e.g., guideline-directed medical therapy (GDMT) beta-blockers, ACE inhibitors, or ARBs] for compelling indications [e.g., previous myocardial infarction (MI), stable angina] as first-line therapy, with the addition of other drugs (e.g., dihydropyridine CCBs, thiazide diuretics, and/or mineralocorticoid receptor antagonists) as needed to further control hypertension.</li> <li>• In adults with SIHD with angina and persistent uncontrolled hypertension, the addition of dihydropyridine CCBs to GDMT beta-blockers is recommended.</li> <li>• In adults who have had a MI or acute coronary syndrome, it is reasonable to continue GDMT beta-blockers beyond three years as long-term therapy for hypertension.</li> <li>• Beta-blockers and/or CCBs might be considered to control hypertension in patients with coronary artery disease (CAD) had an MI more than three years ago and have angina.</li> </ul> <p><u>Heart Failure</u></p> <ul style="list-style-type: none"> <li>• In adults with increased risk of HF, the optimal BP in those with hypertension should be <math>&lt; 130</math> mmHg.</li> <li>• Adults with HFrEF and hypertension should be prescribed GDMT titrated to attain a BP <math>&lt; 130/80</math> mmHg.</li> <li>• Non-dihydropyridine CCBs are not recommended in the treatment of hypertension in adults with HFrEF.</li> <li>• In adults with HFpEF who present with symptoms of volume overload, diuretics should be prescribed to control hypertension.</li> <li>• Adults with HFpEF and persistent hypertension after management of volume overload should be prescribed ACE inhibitors or ARBs and beta-blockers titrated to attain SBP <math>&lt; 130</math> mmHg.</li> </ul> <p><u>CKD</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and CKD should be treated to a BP goal <math>&lt; 130/80</math> mmHg.</li> <li>• In adults with hypertension and CKD [stage 3 or higher or stage 1 or 2 with albuminuria (<math>\geq 300</math> mg/d, or <math>\geq 300</math> mg/g albumin-to-creatinine ratio or the equivalent in the first morning void)], treatment with an ACE inhibitor is reasonable to slow kidney disease progression. Treatment with an ARB may be reasonable if an ACE inhibitor is not tolerated.</li> <li>• After kidney transplantation, it is reasonable to treat patients with hypertension to</li> </ul>

Clinical Guideline	Recommendations
	<p>a BP goal &lt;130/80 mmHg and with a CCB on the basis of improved glomerular filtration rate (GFR) and kidney survival.</p> <p><u>Cerebrovascular Disease</u></p> <ul style="list-style-type: none"> <li>• In adults with intracerebral hemorrhage (ICH) who present with SBP &gt;220 mmHg, it is reasonable to use continuous intravenous (IV) drug infusion and close BP monitoring to lower levels. Immediate lowering of SBP to &lt;140 mmHg in adults with spontaneous ICH who present within six hours of the acute event and have an SBP between 150 mmHg and 220 mmHg is not of benefit to reduce death or severe disability and can be potentially harmful.</li> <li>• Adults with acute ischemic stroke and elevated BP who are eligible for treatment with IV tissue plasminogen activator (tPA) should have their BP slowly lowered to &lt;185/110 mmHg before thrombolytic therapy is initiated.</li> <li>• In adults with an acute ischemic stroke, BP should be &lt;185/110 mmHg before administration of IV tPA and should be maintained below 180/105 mmHg for at least the first 24 hours after initiation drug therapy.</li> <li>• Starting or restarting antihypertensive therapy during hospitalization in patients with BP &gt;140/90 mmHg who are neurologically stable is safe and reasonable to improve long-term BP control, unless contraindicated.</li> <li>• In patient with BP <math>\geq</math>220/120 mmHg who did not receive IV alteplase or endovascular treatment and have no comorbid conditions requiring acute antihypertensive treatment, the benefit of initiating or reinitiating treatment of hypertension within the first 48 to 72 hours is uncertain. It might be reasonable to lower BP by 15% during the first 24 hours after onset of stroke. In patients with BP &lt;220/120 mmHg with the same conditions, initiating or reinitiating treatment of hypertension within the first 48 to 72 hours after an acute ischemic stroke is not effective to prevent death or dependency.</li> <li>• Adults with previously treated stroke or transient ischemic attack should be restarted on antihypertensive treatment after the first few days of the index event to reduce the risk of recurrent stroke and other vascular events. Treatment with a thiazide diuretic, ACE inhibitor, or ARB, or combination treatment consisting of a thiazide diuretic plus ACE inhibitor, is useful.</li> <li>• Adults not previously treated for hypertension who experienced a stroke or transient ischemic attack and have an established BP <math>\geq</math>140/90 mmHg should be prescribed antihypertensive treatment a few days after the index event to reduce the risk of recurrent stroke and other vascular event.</li> <li>• For adults who experience a stroke or transient ischemic attack, selection of specific drugs should be individualized on the basis of patient comorbidities and agent pharmacological class.</li> <li>• For adults who experience a stroke or transient ischemic attack, a BP goal &lt;130/80 mmHg may be reasonable.</li> <li>• For adults with a lacunar stroke, a target SBP goal &lt;130 mmHg may be reasonable.</li> <li>• In adults previously untreated for hypertension who experience an ischemic stroke or transient ischemic attack and have an SBP &lt;140 mmHg and a DBP &lt;90 mmHg, the usefulness of initiating antihypertensive treatment is not well established.</li> </ul> <p><u>Peripheral Artery Disease (PAD)</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and PAD should be treated similarly to patients with hypertension without PAD.</li> </ul> <p><u>Diabetes Mellitus (DM)</u></p> <ul style="list-style-type: none"> <li>• In adults with DM and hypertension, antihypertensive drug treatment should be initiated at a BP of <math>\geq</math>130/80 mmHg with a treatment goal &lt;130/80 mmHg.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In adults with DM and hypertension, all first-line classes of antihypertensive agents (i.e., diuretics, ACE inhibitors, ARBs, and CCBs) are useful and effective.</li> <li>• In adults with DM and hypertension, ACE inhibitors or ARBs may be considered in the presence of albuminuria.</li> </ul> <p><u>Atrial Fibrillation, Valvular Heart Disease, and Aortic disease</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension can be useful for prevention of recurrence of AF.</li> <li>• In adults with asymptomatic aortic stenosis, hypertension should be treated with pharmacotherapy, starting at a low dose and gradually titrating upward as needed.</li> <li>• In patients with chronic aortic insufficiency, treatment of systolic hypertension with agents that do not slow the heart rate (i.e., avoid beta-blockers) is reasonable.</li> <li>• Beta-blockers are recommended as the preferred antihypertensive agents in patients with hypertension and thoracic aortic disease.</li> </ul> <p><u>Racial and Ethnic Differences in Treatment</u></p> <ul style="list-style-type: none"> <li>• In black adults with hypertension but without HF or CKD, including those with DM, initial antihypertensive treatment should include a thiazide-type diuretic or CCB. Two or more antihypertensive medications are recommended to achieve a BP target &lt;130/80 mmHg in most adults with hypertension, especially in black adults with hypertension.</li> </ul> <p><u>Pregnancy</u></p> <ul style="list-style-type: none"> <li>• Women with hypertension who become pregnant, or are planning to become pregnant, should be transitioned to methyldopa, nifedipine, and/or labetalol during pregnancy.</li> <li>• Women with hypertension who become pregnant should not be treated with ACE inhibitors, ARBs, or direct renin inhibitors.</li> </ul> <p><u>Older Persons</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension with an SBP treatment goal &lt;130 mmHg is recommended for noninstitutionalized ambulatory community-dwelling adults (≥65 years of age) with an average SBP of ≥130 mmHg.</li> <li>• For older adults (≥65 years of age) with hypertension and a higher burden of comorbidity and limited life expectancy, clinical judgment, patient preference, and a team-based approach to assess risk/benefit is reasonable for decisions regarding intensity of BP lowering and choice of antihypertensive drugs.</li> </ul> <p><u>Hypertensive Crises</u></p> <ul style="list-style-type: none"> <li>• In adults with a hypertensive emergency, admission to an intensive care unit is recommended for continuous monitoring of BP and target organ damage and for parenteral administration of an appropriate agent.</li> <li>• For adults with a compelling condition (i.e., aortic dissection, severe pre-eclampsia or eclampsia, or pheochromocytoma crisis), SBP should be reduced to &lt;140 mmHg during the first hour and to &lt;120 mmHg in aortic dissection.</li> <li>• For adults without a compelling condition, SBP should be reduced by no more than 25% within the first hours; then, if stable, to 160/100 mmHg within the next two to six hours; and then cautiously to normal during the following 24 to 48 hours.</li> </ul> <p><u>Cognitive Decline and Dementia</u></p> <ul style="list-style-type: none"> <li>• In adults with hypertension, BP lowering is reasonable to prevent cognitive decline and dementia.</li> </ul> <p><u>Patients Undergoing Surgical Procedures</u></p>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In patients with hypertension undergoing major surgery who have been on beta-blockers chronically, beta-blockers should be continued.</li> <li>• In patients with hypertension undergoing planned elective major surgery, it is reasonable to continue medical therapy for hypertension until surgery.</li> <li>• In patients with hypertension undergoing major surgery, discontinuation of ACE inhibitors or ARBs perioperatively may be considered.</li> <li>• In patients with planned elective major surgery and SBP <math>\geq</math>180 mmHg or DBP <math>\geq</math>110 mmHg, deferring surgery may be considered.</li> <li>• For patients undergoing surgery, abrupt pre-operative discontinuation of beta-blockers or clonidine is potentially harmful.</li> <li>• Beta-blockers should not be started on the day of surgery in beta-blocker-naïve patients.</li> <li>• Patients with intraoperative hypertension should be managed with IV medications until such time as oral medications can be resumed.</li> </ul>
<p>American Diabetes Association: <b>Standards of Medical Care in Diabetes (2022)</b><sup>40</sup></p>	<p><b>Hypertension/blood pressure control</b></p> <ul style="list-style-type: none"> <li>• Blood pressure should be measured at every routine visit. When possible, patients found to have elevated blood pressure (<math>\geq</math>140/90) should have blood pressure confirmed using multiple readings, including measurements on a separate day, to diagnose hypertension. Patients with blood pressure <math>\geq</math>180/110 and cardiovascular disease could be diagnosed with hypertension at a single visit.</li> <li>• All hypertensive patients with diabetes should monitor their blood pressure at home.</li> <li>• For patients with diabetes and hypertension, with diabetes and hypertension, blood pressure targets should be individualized through a shared decision-making process that addresses cardiovascular risk, potential adverse effects of antihypertensive medications, and patient preferences.</li> <li>• For individuals with diabetes and hypertension at higher cardiovascular risk (existing atherosclerotic cardiovascular disease [ASCVD] or 10-year ASCVD risk <math>\geq</math>15%), a blood pressure target of <math>&lt;</math>130/80 mmHg may be appropriate, if it can be safely attained.</li> <li>• For individuals with diabetes and hypertension at lower risk for cardiovascular disease (10-year atherosclerotic cardiovascular disease risk <math>&lt;</math>15%), treat to blood pressure target of <math>&lt;</math>140/90.</li> <li>• In pregnant patients with diabetes and preexisting hypertension, a blood pressure target of 110 to 135/85 is suggested in the interest of reducing the risk for accelerated maternal hypertension and minimizing impaired fetal growth.</li> <li>• For patients with blood pressure <math>&gt;</math>120/80, lifestyle intervention consists of weight loss when indicated, a Dietary Approaches to Stop Hypertension (DASH)-style eating pattern including reducing sodium and increasing potassium intake, moderation of alcohol intake, and increased physical activity.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq</math>140/90 mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of pharmacologic therapy to achieve blood pressure goals.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq</math>160/100 mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of two drugs or a single pill combination of drugs demonstrated to reduce cardiovascular events in patients with diabetes.</li> <li>• Treatment for hypertension should include drug classes demonstrated to reduce cardiovascular events in patients with diabetes (ACE inhibitors, angiotensin receptor blockers, thiazide-like diuretics, or dihydropyridine calcium channel blockers). ACE inhibitors or angiotensin receptor blockers are recommended first-line therapy for hypertension in people with diabetes and coronary artery disease.</li> <li>• Multiple-drug therapy is generally required to achieve blood pressure targets (but not a combination of ACE inhibitors and angiotensin receptor blockers).</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• An ACE inhibitor or angiotensin receptor blocker, at the maximum tolerated dose indicated for blood pressure treatment, is the recommended first-line treatment for hypertension in patients with diabetes and urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine or 30 to 299 mg/g creatinine. If one class is not tolerated, the other should be substituted.</li> <li>• For patients treated with an ACE inhibitor, angiotensin receptor blocker, or diuretic, serum creatinine/estimated glomerular filtration rate and serum potassium levels should be monitored at least annually.</li> <li>• Patients with hypertension who are not meeting blood pressure targets on three classes of antihypertensive medications (including a diuretic) should be considered for mineralocorticoid receptor antagonist therapy.</li> </ul> <p><u>Chronic kidney disease</u></p> <ul style="list-style-type: none"> <li>• At least once a year, assess urinary albumin (e.g., spot urinary albumin-to-creatinine ratio) and estimated glomerular filtration rate in patients with type 1 diabetes with duration of five or more years and in all patients with type 2 diabetes.</li> <li>• Patients with diabetes and urinary albumin <math>\geq 300</math> mg/g creatinine and/ or an estimated glomerular filtration rate 30 to 60 mL/min/1.73 m<sup>2</sup> should be monitored twice annually to guide therapy.</li> <li>• Optimize glucose control to reduce the risk or slow the progression of chronic kidney disease (CKD).</li> <li>• For patients with type 2 diabetes and diabetic kidney disease, use of a sodium-glucose cotransporter 2 inhibitor in patients with an estimated glomerular filtration rate <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> and urinary albumin <math>\geq 300</math> mg/g creatinine is recommended to reduce CKD progression and cardiovascular events.</li> <li>• In patients with type 2 diabetes and CKD, consider use of sodium-glucose cotransporter 2 inhibitors additionally for cardiovascular risk reduction when estimated glomerular filtration rate and urinary albumin creatinine are <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> or <math>\geq 300</math> mg/g, respectively.</li> <li>• In patients with CKD who are at increased risk for cardiovascular events or CKD progression and are unable to use a sodium-glucose cotransporter 2 inhibitor, a nonsteroidal mineralocorticoid receptor antagonist (finerenone) is recommended to reduce CKD progression and cardiovascular events.</li> <li>• Optimize blood pressure control and reduce blood pressure variability to reduce the risk or slow the progression of CKD.</li> <li>• Do not discontinue renin-angiotensin system blockade for minor increases in serum creatinine (<math>\leq 30\%</math>) in the absence of volume depletion.</li> <li>• For people with nondialysis-dependent stage 3 or higher CKD, dietary protein intake should be a maximum of 0.8 g/kg body weight per day (the recommended daily allowance). For patients on dialysis, higher levels of dietary protein intake should be considered, since malnutrition is a major problem in some dialysis patients.</li> <li>• In nonpregnant patients with diabetes and hypertension, either an ACE inhibitor or an angiotensin receptor blocker is recommended for those with modestly elevated urinary albumin-to-creatinine ratio (30 to 299 mg/g creatinine) and is strongly recommended for those with urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine and/or estimated glomerular filtration rate <math>&lt; 60</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Periodically monitor serum creatinine and potassium levels for the development of increased creatinine or changes in potassium when ACE inhibitors, angiotensin receptor blockers, or diuretics are used.</li> <li>• An ACE inhibitor or an angiotensin receptor blocker is not recommended for the primary prevention of CKD in patients with diabetes who have normal blood pressure, normal urinary albumin-to-creatinine ratio (<math>&lt; 30</math> mg/g creatinine), and normal estimated glomerular filtration rate.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"><li data-bbox="500 205 1414 268">• Patients should be referred for evaluation by a nephrologist if they have an estimated glomerular filtration rate &lt;30 mL/min/1.73 m<sup>2</sup>.</li><li data-bbox="500 268 1414 321">• Promptly refer to a nephrologist for uncertainty about the etiology of kidney disease, difficult management issues, and rapidly progressing kidney disease.</li></ul>

### III. Indications

The FDA-approved indications for the angiotensin II receptor antagonists are noted in Tables 3 and 4. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively on the results of such clinical trials.

**Table 3. FDA-Approved Indications for the Angiotensin II Receptor Antagonists-Single Entity Agents<sup>3-20</sup>**

Indication(s)	Single Entity Agents							
	Azil-sartan	Cande-sartan		Irbe-sartan	Lo-sartan	Olme-sartan	Telmi-sartan	Val-sartan
<b>Cardiovascular Risk Reduction</b>								
Reduce the risk of cardiovascular mortality in clinically stable patients with left ventricular failure or left ventricular dysfunction following myocardial infarction								✓
Reduce the risk of myocardial infarction, stroke, or death from cardiovascular causes in patients ≥55 years of age at high risk of developing major cardiovascular events who are unable to take an angiotensin converting enzyme inhibitor							✓	
Reduce the risk of stroke in patients with hypertension and left ventricular hypertrophy					✓ *			
<b>Heart Failure</b>								
Heart failure (New York Heart Association functional class II to IV)								✓
Heart failure (New York Heart Association functional class II to IV) in adults with left ventricular systolic dysfunction (ejection fraction ≤40%) to reduce cardiovascular death and to reduce heart failure hospitalizations		✓						
<b>Hypertension</b>								
Hypertension, alone or in combination with other antihypertensive agents	✓	✓	✓	✓	✓	✓	✓	✓
<b>Nephropathy in Type 2 Diabetic Patients</b>								
Diabetic nephropathy with an elevated serum creatinine and proteinuria (>300 mg/day) in patients with type 2 diabetes and hypertension				✓	✓			

\*There is evidence that this benefit does not apply to Black patients.

Telmisartan and amlodipine	64 to 90/ 42 to 58	99.5/93	Hepatic, minimal (% not reported)/ Hepatic (90)	Feces (>97) Renal (<1)/ Feces (20 to 25) Renal (10)	24/ 30 to 50
Telmisartan and HCTZ	42 to 58/Not reported	Not reported/Not reported	Not reported/Not reported	Feces (97)/ Renal (61)	24/ 5.6 to 14.8
Valsartan and HCTZ	25/70	95/40 to 70	Liver, minimal (% not reported)/ Not reported	Feces (83) Renal (13)/ Renal (70)	6 to 9/ 10 to 12

HCTZ=hydrochlorothiazide

## V. Drug Interactions

Major drug interactions with the angiotensin II receptor antagonists are listed in Table 6.

**Table 6. Major Drug Interactions with the Angiotensin II Receptor Antagonists<sup>21</sup>**

Generic Name(s)	Interaction	Mechanism
ARBs (azilsartan, candesartan, irbesartan, losartan, olmesartan, telmisartan, valsartan)	ACE inhibitors	Concurrent use of angiotensin converting enzyme inhibitors and ARBs may result in increased risk of adverse events (i.e., hypotension, syncope, hyperkalemia, changes in renal function, acute renal failure).
ARBs (azilsartan, irbesartan)	Fluconazole	Concurrent use of fluconazole and selected ARBs may result in increased exposure of ARB and increased risk of toxicity.
ARBs (azilsartan, candesartan, irbesartan, losartan, olmesartan, telmisartan, valsartan)	Lithium	Angiotensin II receptor antagonists may decrease lithium renal excretion by enhancing its reabsorption. Lithium levels may increase, resulting in an increase in pharmacologic and toxic effects of lithium.
ARBs (azilsartan, candesartan, irbesartan, losartan, olmesartan, telmisartan, valsartan)	Trimethoprim	Angiotensin II receptor antagonists and trimethoprim may act additively or synergistically to inhibit renal excretion of potassium, increasing the risk of hyperkalemia.
ARBs (azilsartan, candesartan, irbesartan, losartan, olmesartan, telmisartan, valsartan)	Aliskiren	Concurrent use of aliskiren and ARBs may result in an increased risk of hyperkalemia, renal impairment, and hypotension.
Telmisartan	Digoxin	Concurrent use of digoxin and telmisartan may result in an increased risk of digoxin toxicity (nausea, vomiting, arrhythmias).
Dihydropyridines (amlodipine)	HIV protease inhibitors	Pharmacologic effects of amlodipine may be enhanced by protease inhibitors.
Dihydropyridines (amlodipine)	Imidazoles	Imidazoles may increase the plasma concentrations and pharmacologic effects of amlodipine.
Thiazide diuretics (HCTZ)	Dofetilide	Thiazide diuretics may induce hypokalemia which may increase the risk of torsades de pointes.
Thiazide diuretics (HCTZ)	Lithium	Thiazide diuretics decrease the renal clearance of lithium which leads to increased serum lithium levels. Lithium toxicity has occurred.
Thiazide diuretics (HCTZ)	Diazoxide	The combination of diazoxide with a thiazide diuretic may lead to hyperglycemia through an unknown mechanism; therefore the combination should be avoided.
Thiazide diuretics (HCTZ)	Digitalis glycosides	Diuretic-induced electrolyte disturbances may predispose the patient to digitalis-induced cardiac arrhythmias.

ACE inhibitor=angiotensin converting enzyme inhibitor, ARB=angiotensin II receptor antagonist, HCTZ=hydrochlorothiazide, HIV=human immunodeficiency virus

## VI. Adverse Drug Events

The most common adverse drug events reported with the angiotensin II receptor antagonists are listed in Table 7. The most common adverse drug events reported with amlodipine and hydrochlorothiazide are listed in Table 8. The boxed warning for the angiotensin II receptor antagonists is listed in Table 9.

**Table 7. Adverse Drug Events (%) Reported with the Combination Angiotensin II Receptor Antagonists-Single Entity Agents<sup>3-20</sup>**

Adverse Events	Single Entity Agents

**Table 9. Boxed Warning for the Angiotensin II Receptor Antagonists<sup>20,21</sup>**

<b>WARNING</b>
When pregnancy is detected, discontinue therapy as soon as possible. Drugs that act directly on the renin-angiotensin system can cause injury and even death to the developing fetus.

## VII. Dosing and Administration

The usual dosing regimens for the angiotensin II receptor antagonists are listed in Table 10.

**Table 10. Usual Dosing Regimens for the Angiotensin II Receptor Antagonists<sup>3-21</sup>**

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
<b>Single Entity Agents</b>			
Azilsartan	<u>Hypertension:</u> Tablet: initial, 40 or 80 mg once daily; maintenance, 80 mg once daily	Safety and efficacy in children have not been established.	Tablet: 40 mg 80 mg
Candesartan	<u>Heart Failure:</u> Tablet: initial, 4 mg once daily; maintenance, 32 mg once daily  <u>Hypertension:</u> Tablet: initial, 16 mg once daily when used as monotherapy in patients who are not volume-depleted; maintenance: 8 to 32 mg/day in a single or divided dose(s)	<u>Hypertension in children 1 to 6 years of age:</u> Tablet: initial, 0.2 mg/kg/day; maintenance, 0.05 to 0.4 mg/kg/day  <u>Hypertension in children 7 to 17 years of age and &lt;50 kg:</u> Tablet: initial, 4 to 8 mg/day; maintenance, 2 to 16 mg/day  <u>Hypertension in children 7 to 17 years of age and &gt;50 kg:</u> Tablet: initial, 8 to 16 mg/day; maintenance, 4 to 32 mg/day  Safety and efficacy in children with heart failure have not been established.	Tablet: 4 mg 8 mg 16 mg 32 mg
Irbesartan	<u>Diabetic nephropathy:</u> Tablet: 300 mg once daily  <u>Hypertension:</u> Tablet: initial, 150 mg once daily in patients who are not volume-depleted; maximum, 300 mg once daily	Safety and efficacy in children have not been established.	Tablet: 75 mg 150 mg 300 mg
Losartan	<u>Cerebrovascular risk reduction (hypertension and left ventricular hypertrophy):</u> Tablet: initial, 50 mg once daily; maintenance, 100 mg once daily  <u>Diabetic nephropathy:</u> Tablet: initial, 50 mg once daily; maintenance, dose should be increased to 100 mg once daily based on blood pressure response	<u>Hypertension in children ≥6 years of age:</u> Tablet: initial, 0.7 mg/kg once daily (up to 50 mg total); maximum, >1.4 mg/kg/day (or in excess of 100 mg) have not been studied  Safety and efficacy in children <6 years of age have not been established.	Tablet: 25 mg 50 mg 100 mg

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
	<u>Hypertension:</u> Tablet: initial, 50 mg once daily in patients who are not volume-depleted; maintenance, 25 to 100 mg/day in a single or divided dose(s)		
Olmesartan	<u>Hypertension:</u> Tablet: initial, 20 mg once daily when used as monotherapy in patients who are not volume depleted; maximum, 40 mg once daily	<u>Hypertension in children 6 to 16 years of age and 20 to &lt;35 kg:</u> Tablet: initial, 10 mg once daily; maximum, 20 mg once daily  <u>Hypertension in children 6 to 16 years of age &gt;35 kg:</u> Tablet: initial, 20 mg once daily; maximum, 40 mg once daily  Safety and efficacy in children <6 years of age have not been established.	Tablet: 5 mg 20 mg 40 mg
Telmisartan	<u>Cardiovascular risk reduction:</u> Tablet: 80 mg once daily  <u>Hypertension:</u> Tablet: initial, 40 mg once daily; maximum: 80 mg per day	Safety and efficacy in children have not been established.	Tablet: 20 mg 40 mg 80 mg
Valsartan	<u>Cardiovascular risk reduction (post-myocardial infarction):</u> Tablet: initial, 20 mg twice daily; maintenance: 160 mg twice daily  <u>Heart Failure:</u> Tablet: Initial, 40 mg twice daily; maintenance, up titrate to 80 to 160 mg twice daily; maximum, 320 mg in divided doses  <u>Hypertension:</u> Tablet: initial, 80 to 160 mg once daily when used as monotherapy in patients who are not volume depleted; maintenance, 80 to 320 mg once daily	<u>Hypertension in children 1 to 16 years of age:</u> Tablet: initial, 1 mg/kg once daily (up to 40 mg total) administered as a tablet or suspension; maximum, >4 mg/kg/day (or in excess of 160 mg) have not been studied  <u>Safety and efficacy in children with hypertension &lt;1 years of age, or with heart failure, or for cardiovascular risk reduction have not been established.</u>	Tablet: 40 mg 80 mg 160 mg 320 mg
<b>Combination Products</b>			
Azilsartan and chlorthalidone	<u>Hypertension:</u> Tablet: initial, 40-12.5 mg once daily; maintenance, 40-25 mg once daily; maximum, 40-25 mg /day	Safety and efficacy in children have not been established.	Tablet: 40-12.5 mg 40-25 mg
Candesartan and HCTZ	<u>Hypertension:</u> Tablet: 16-12.5 to 32-25 mg/day	Safety and efficacy in children have not been established.	Tablet: 16-12.5 mg 32-12.5 mg 32-25 mg

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
Irbesartan and HCTZ	<u>Hypertension:</u> Tablet: initial, 150-12.5 mg once daily; maximum, 300-25 mg once daily	Safety and efficacy in children have not been established.	Tablet: 150-12.5 mg 300-12.5 mg
Losartan and HCTZ	<u>Cerebrovascular risk reduction (hypertension and left ventricular hypertrophy):</u> Tablet: initial, 50-12.5 mg once daily; maintenance, 100-12.5 mg once daily; maximum, 100-25 mg once daily  <u>Hypertension:</u> Tablet: initial, 50-12.5 mg once daily; maintenance, 100-12.5 mg once daily; maximum, 100-25 mg once daily	Safety and efficacy in children have not been established.	Tablet: 50-12.5 mg 100-12.5 mg 100-25 mg
Olmesartan and amlodipine and HCTZ	<u>Hypertension:</u> Tablet: maximum, 40-10-25 mg once daily	Safety and efficacy in children have not been established.	Tablet: 20-5-12.5 mg 40-5-12.5 mg 40-5-25 mg 40-10-12.5 mg 40-20-25 mg
Olmesartan and HCTZ	<u>Hypertension:</u> Tablet: 20-12.5 to 40-25 mg/day	Safety and efficacy in children have not been established.	Tablet: 20-12.5 mg 40-12.5 mg 40-25 mg
Telmisartan and amlodipine	<u>Hypertension:</u> Tablet: initial, 40-5 or 80-5 mg once daily; maintenance, titrate as needed; maximum , 80-10 mg once daily	Safety and efficacy in children have not been established.	Tablet: 40-5 mg 40-10 mg 80-5 mg 80-10 mg
Telmisartan and HCTZ	<u>Hypertension:</u> Tablet: 40-12.5 to 80-25 mg once daily	Safety and efficacy in children have not been established.	Tablet: 40-12.5 mg 80-12.5 mg 80-25 mg
Valsartan and HCTZ	<u>Hypertension:</u> Tablet: 80-12.5 to 320-25 mg once daily	Safety and efficacy in children have not been established.	Tablet: 80-12.5 mg 160-12.5 mg 160-25 mg 320-12.5 mg 320-25 mg

HCTZ=hydrochlorothiazide

## VIII. Effectiveness

Clinical studies evaluating the safety and efficacy of the angiotensin II receptor antagonists are summarized in Table 11.

**Table 11. Comparative Clinical Trials with the Angiotensin II Receptor Antagonists**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<b>Cardiovascular Risk Reduction</b>				
Pfeffer et al. <sup>41</sup> (2003) VALIANT  Captopril 50 mg TID  vs  valsartan 160 mg BID  vs  valsartan 80 mg BID and captopril 50 mg TID	DB, MC, RCT  Patients ≥18 years of age with an acute MI that was complicated by clinical or radiologic signs of heart failure and/or evidence of left ventricular systolic dysfunction	N=14,703  24.7 months	Primary: All-cause mortality  Secondary: Death from cardiovascular causes, recurrent MI, hospitalization for heart failure	Primary: No significant difference in all-cause mortality was reported between valsartan monotherapy and captopril monotherapy (P=0.98).  No significant difference in all-cause mortality was observed between valsartan plus captopril combination therapy and captopril monotherapy (P=0.73).  Secondary: The rate of death from cardiovascular causes, reinfarction, or hospitalization for heart failure was not significantly different between valsartan and captopril monotherapy (P=0.20).  The rate of death from cardiovascular causes, reinfarction, or hospitalization for heart failure was not significantly different between valsartan and captopril combination therapy and captopril monotherapy (P=0.37).  Combination therapy had the most drug-related adverse events. With monotherapy, hypotension and renal dysfunction were more common in the valsartan group and cough, rash, and taste disturbance were more common in the captopril group.
Dickstein et al. <sup>42</sup> (2002) OPTIMAAL  Captopril 50 mg TID  vs  losartan 50 mg QD	DB, MC, PG, RCT  Patients ≥50 years with an acute MI and signs or symptoms of heart failure during the acute phase or a new Q-wave anterior infarction or	N=5,477  2.7 years (mean)	Primary: All-cause mortality  Secondary: Composite of sudden cardiac death or resuscitated cardiac arrest	Primary: No significant difference in all-cause mortality was reported between patients receiving losartan and captopril (18 vs 16%, respectively; RR, 1.13; 95% CI, 0.99 to 1.28; P=0.07).  Secondary: No significant difference in sudden cardiac death or resuscitated cardiac arrest was reported between patients receiving losartan and captopril (9 vs 7%; RR, 1.19; 95% CI, 0.98 to 1.43; P=0.07).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
	reinfarction			Losartan was significantly better tolerated than captopril, with fewer patients discontinuing study medication (17 vs 23%; P<0.0001).
Graham et al. <sup>43</sup> (2014)  Olmesartan  vs  other ARBs	Cohort, RETRO  Medicare patients (age 65 years or older) who filled at least one ARB prescription and had no recorded prescription for an ACE inhibitor or ARB 6 months prior to initiating a study drug. Results also stratified by diabetes or no diabetes	N=882,727  Mean duration of study drug use was 130 days	Primary: Acute MI, stroke, and all-cause mortality enriched for acute cardiovascular death  Secondary: Not reported	Primary: In the combined study population, there was no difference in the HRs for acute MI or stroke. The HR for death was reduced for olmesartan compared with other ARB users (HR, 0.82; 95% CI, 0.73 to 0.93; P=0.002).  In strata defined by presence or absence of diabetes, there was no difference in risk between users of olmesartan and other ARBs for any study endpoint at lower doses of therapy, regardless of duration of use. With high-dose therapy, the risk of acute MI was nonsignificantly increased in diabetic patients treated for 6 months or longer with olmesartan. For nondiabetic patients, the risk of acute MI was statistically significantly reduced with high-dose olmesartan over all durations combined. There was no effect of dose or duration on stroke risk with olmesartan in diabetic or nondiabetic patients.  Mortality risk was increased in diabetic patients treated with high-dose olmesartan for 6 months or longer (HR, 2.03; 95% CI, 1.09 to 3.75; P=0.02) and was reduced in nondiabetic patients during the first 6 months of olmesartan use (HR, 0.72; 95% CI, 0.55 to 0.96; P=0.02), and with use of 6 months or longer (HR, 0.46; 95% CI, 0.24 to 0.86; P=0.01).  Secondary: Not reported

White et al. <sup>44</sup> (2016)  Azilsartan medoxomil 40 or 80 mg  vs  olmesartan 40 mg  vs	Pooled analysis of 3 DB, PC or AC, RCTs  Patients with impaired fasting glucose (prediabetes mellitus) and T2DM	N=3821  6 to 8 weeks	Primary: Changes from baseline in both 24-h and clinic SBP  Secondary: Safety and tolerability	Primary: Baseline 24-h mean SBPs were approximately 145 and 146mmHg in the prediabetes mellitus and T2DM subgroups, respectively; corresponding clinic SBPs were approximately 158 and 159mmHg. Baseline HbA1c values for each subgroup were normoglycemic, 5.3%; prediabetes mellitus, 6.0%; and T2DM, 6.9%. Changes from baseline in 24-h or clinic SBP were significantly greater with azilsartan, 80mg compared with either olmesartan 40mg or valsartan 320mg in all subgroups in each pool.  Secondary: Safety and tolerability were similar among the active treatment and placebo subgroups.

vs  spironolactone 25 mg/day plus irbesartan 150 mg/day and ramipril 5 mg/day				compared to the other treatments (P=0.046). There was no difference in SBP among the treatments (P value not reported).  There were no differences in creatinine clearance among the treatments (P>0.05).  Gynecomastia was not observed with any of the treatments.
Bianchi et al. <sup>50</sup> (2010)  Ramipril 10 mg and atorvastatin 10 mg QD (conventional therapy)  vs  spironolactone 25 mg, ramipril 10 mg, irbesartan 300 mg, and atorvastatin 10 mg QD (intensive therapy)  The addition of diuretics, calcium antagonists, $\beta$ -blockers or $\alpha$ 1-receptor antagonists were added to achieve blood pressure <130/80 mm Hg	RCT, OL  Patients with a clinical diagnosis of idiopathic chronic glomerulonephritis and urine protein-creatinine ratio >1 g/g	N=128  36 months	Primary: Changes over time in proteinuria and eGFR  Secondary: Adverse events, drop outs	Primary: SBP decreased more in the intensive-therapy group (from 156.6 to 113.5 mm Hg) than in the conventional therapy group (from 155.7 to 122.7 mm Hg; P<0.01).  Urine protein excretion decreased from 2.65 to 0.45 g/g creatinine with intensive therapy (P<0.001). With conventional therapy, urine protein excretion decreased from 2.60 to 1.23 g/g creatinine (P<0.001).  With intensive therapy, eGFR did not significantly change over time (64.6 vs 62.9 mL/min/1.73 m <sup>2</sup> ). With conventional therapy, eGFR decreased from 62.5 to 55.8 mL/min/1.73 m <sup>2</sup> (P<0.01).  Secondary: In the conventional therapy group, eight patients discontinued the study due to hyperkalemia, cough, and rapid deterioration in kidney function. In the intensive therapy group, 15 dropped out due to hyperkalemia, cough, and hypotension. Nine patients in the intensive therapy group developed gynecomastia. Twelve patients on conventional and 31 on intensive therapy had to interrupt the study temporarily because of low blood pressure. No patient developed an increase in creatine kinase, alanine aminotransferase, and alkaline phosphatase levels during the study.
Brenner et al. <sup>51</sup> (2001)	DB, PC, RCT	N=1,513	Primary: Composite of risk of	Primary: Compared to placebo, losartan resulted in a 16% reduction of composite

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
RENAAL  Losartan 50 to 100 mg QD  vs  placebo	Patients 31 to 70 years of age with HTN, type 2 diabetes mellitus and nephropathy on conventional antihypertensive therapy	3.4 years	doubling of serum creatinine, ESRD, or death from any cause  Secondary: Composite of morbidity and mortality from cardiovascular causes, proteinuria, rate of progression of renal disease	primary end point (P=0.02).  Losartan treatment produced a 25% reduction of doubling serum creatinine vs placebo (P=0.006) and 28% reduction in ESRD vs placebo (P=0.002).  No differences in mortality were reported (P=0.88).  Secondary: There was no significant difference between the losartan and placebo groups in the composite end point of morbidity and mortality from cardiovascular causes.  Losartan treatment led to an average reduction in the level of proteinuria by 35% (P<0.001 vs placebo).  Losartan reduced the rate of decline in renal function by 18% (P=0.01 vs placebo).
Kiernan et al. <sup>52</sup> (2015) HEAAL  Losartan 50 mg  vs  losartan 150 mg	DB, MC, RCT  Patients with HF <sub>r</sub> EF, NYHA functional class II to IV; LVEF ≤40%; stable cardiovascular medical therapy for at least two weeks; and known intolerance to ACEIs	N=3,843	Primary: eGFR levels, SCr, renal function and association with clinical outcomes  Secondary: Not reported	Primary: Compared with 50 mg, 150 mg losartan led to a greater reduction in eGFR across time (mean difference, -3.76 ml/min/1.73 m <sup>2</sup> ; P<0.0001). This difference was driven by early changes, and differences in eGFR after four months were not significant (mean difference, 0.42 ml/min/1.73 m <sup>2</sup> ; P=0.15). Although an increase in SCr >0.3 mg/dL from baseline was associated with increased risk of death or hospitalization for HF (HR, 1.36; P<0.0001), the relationship was not significant if the change occurred before four months (HR, 1.09; P=0.20). Despite increased risk of worsening renal function, 150 mg losartan was associated with reduced risk of death or hospitalization for HF compared with 50 mg (HR, 0.85; P<0.0001).  Secondary: Not reported
Hou et al. <sup>53</sup> (2007) ROAD  Benazepril 10 mg/day vs	OL, PRO, RCT  Patients aged 18 to 70 years with proteinuria and chronic renal	N=360  3.7 years (median follow-up)	Primary: Time to composite of doubling of serum creatinine, ESRD or death	Primary: Compared to the conventional dosages, optimal antiproteinuric dosages of benazepril and losartan that were achieved through up-titration were associated with a 51 and 53% reduction in the risk for the primary end point (P=0.028 and P=0.022, respectively).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>individual up-titration (10 to 40 mg/day with median dose of 20 mg/day)</p> <p>or</p> <p>losartan 50 mg/day vs individual up-titration (50 to 200 mg/day with median dose of 100 mg/day)</p> <p>Up-titration was performed to optimal antiproteinuric and tolerated dosages, and then these dosages were maintained.</p>	<p>insufficiency who did not have diabetes</p>		<p>Secondary: Changes in level of proteinuria, rate of progression of renal disease</p>	<p>There was no statistically significant difference between benazepril and losartan in the overall relative risk reduction at their respective optimal antiproteinuric dosages or at conventional dosages.</p> <p>Secondary: Optimal antiproteinuric dosages of benazepril and losartan at comparable blood pressure control, achieved a greater reduction in both proteinuria and the rate of decline in renal function compared to their conventional dosages.</p> <p>There was no significant difference in proteinuria reduction between benazepril and losartan at both conventional and optimal antiproteinuric dosages. Changes in renal function were similar between benazepril and losartan arms at both conventional and optimal antiproteinuric doses (P&gt;0.05).</p> <p>There was no significant difference for the overall incidence of major adverse events between groups that were given conventional and optimal dosages in any of the treatment arms.</p>
<p>Fried et al.<sup>54</sup> (2013) VA NEPHRON-D</p> <p>Losartan with lisinopril</p> <p>vs</p> <p>losartan alone</p>	<p>DB, MA, RCT</p> <p>Veterans with proteinuric diabetic kidney disease, an estimated GFR of 30.0 to 89.9 ml/minute/1.73 m<sup>2</sup>, and a urinary albumin-to-creatinine ratio of ≥300</p>	<p>N=1448</p> <p>Median follow-up 2.2 years</p>	<p>Primary: First occurrence of a decline in the eGFR (an absolute decrease of ≥30 ml/minute/1.73 m<sup>2</sup> if the eGFR was ≥60 ml/minute/1.73 m<sup>2</sup> at randomization or a relative decrease of ≥50% if the eGFR was &lt;60 ml/minute/1.73 m<sup>2</sup>), ESRD, or death</p>	<p>The trial was stopped early because the absolute risk of serious adverse events appeared to be greater than the potential benefit of reducing primary end-point events.</p> <p>Primary: There were 152 primary end-point events in the monotherapy group (21.0%) and 132 in the combination-therapy group (18.2%). The risk of the primary end point did not differ significantly between the two groups.</p> <p>Secondary: There were 101 secondary end-point events (a decline in the estimated GFR or ESRD) in the monotherapy group (14.0%) and 77 events in the combination-therapy group (10.6%). There was no significant between-group difference in mortality or ESRD (Table 2), though the number of ESRD events was small.</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
			<p>Secondary: First occurrence of a decline in the eGFR or ESRD</p> <p>Tertiary: CV events, slope of change in eGFR, and change in albuminuria at 1 year</p>	<p>Tertiary: There was no significant difference in the rate of cardiovascular events between the two groups. There was no significant difference in treatment effect on the decline in the estimated GFR (P=0.17). During adjustment of the losartan dose, the median urinary albumin-to-creatinine ratio declined from 959 to 807 (P=0.001). There was a further decline from randomization to 1 year, with a greater decline in the combination-therapy group (from 786 to 517) than in the monotherapy group (from 829 to 701) (P&lt;0.001).</p>
<p>Nakao et al.<sup>55</sup> (2003) COOPERATE</p> <p>Trandolapril 3 mg/day</p> <p>vs</p> <p>losartan 100 mg/day</p> <p>vs</p> <p>trandolapril and losartan at equivalent doses</p>	<p>DB, MC, PC, RCT</p> <p>Patients aged 18 to 70 years with chronic nephropathy (nondiabetic renal disease)</p>	<p>N=263</p> <p>3 years</p>	<p>Primary: Composite of time to doubling of serum creatinine or ESRD</p> <p>Secondary: Changes in blood pressure, daily urinary protein excretion, adverse effects</p>	<p>Primary: The combined end point was reached in 11% of patients in the combination trandolapril and losartan group compared to 23% of patients in the trandolapril (P=0.018) and 23% of patients in the losartan group (P=0.016).</p> <p>Secondary: Mean SBP and DBP reductions were similar among the three treatment groups (P=0.109).</p> <p>All patients receiving active treatment had significant decreases in urinary protein excretion, but the greatest difference was seen with the combination trandolapril and losartan group compared to trandolapril or losartan (-75.6, -44.3, and -42.1%, respectively; P=0.01).</p> <p>The frequency of adverse events did not differ between groups, although a slightly higher occurrence of hyperkalemia and dry cough was recorded in the trandolapril and combination groups than in the losartan group.</p>
<p>Mann et al.<sup>56</sup> (2009) TRANSCEND</p> <p>Telmisartan 80 mg QD</p> <p>vs</p>	<p>DB, MC, PC, RCT</p> <p>Adults with known cardiovascular disease or diabetes with end-organ damage but without macroalbuminuria or heart failure who</p>	<p>N=5927</p> <p>56 months</p>	<p>Primary: Composite outcome: first occurrence of dialysis, renal transplant, doubling of serum creatinine, or death</p>	<p>Primary: The composite outcome of dialysis, doubling of serum creatinine, or death did not significantly differ between the telmisartan and placebo groups (412 patients [14.0%] vs 381 patients [12.8%]; HR, 1.10 [CI, 0.95 to 1.26]; P=0.193).</p> <p>The incidence of the composite outcome of dialysis or doubling of serum creatinine was similar with telmisartan and placebo (58 patients [1.96%] vs 46 patients [1.55%]; HR, 1.29 [95% CI, 0.87 to 1.89]; P=0.20).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
placebo	cannot tolerate ACE inhibitors		Secondary: Changes in the eGFR, progression of proteinuria, and individual components of the primary outcome	Secondary: Doubling of serum creatinine was more frequent with telmisartan than with placebo (56 vs 36 patients; P=0.031).  Decreases in eGFR were greater with telmisartan than with placebo (mean change in eGFR, -3.2 mL/min per 1.73 m <sup>2</sup> [SD, 18.3] vs -0.26 mL/min per 1.73 m <sup>2</sup> [SD, 18.0]; P <0.001).
Foulquier et al. <sup>57</sup> (2014) TRANSCEND  Telmisartan 80 mg QD  vs  placebo	Post-hoc analysis  Patients in the TRANSCEND trial stratified by hypertensive and nonhypertensive	N=5927  56 months	Primary: Composite outcome: first occurrence of dialysis, renal transplant, doubling of serum creatinine, or death  Secondary: Changes in the eGFR, progression of proteinuria, and individual components of the primary outcome	Primary: For the primary four-fold endpoint, No difference in the effect of treatment between hypertensive and nonhypertensive patients was found. No significant improvement with telmisartan over placebo in both hypertensive and nonhypertensive patients was seen.  Secondary: New onset of LVH, evaluated by ECG, was significantly less in hypertensive and nonhypertensive patients treated with telmisartan (hypertensive patients: -36%; P=0.0002; nonhypertensive patients: -58%; P=0.027).  Albuminuria increased less with telmisartan than with placebo in the hypertensive population, as the risks for new microalbuminuria and macroalbuminuria were lower than with placebo (P=0.0004 and P=0.009, respectively). In the nonhypertensive population, the risks were not modified by the treatment. However, according to the interaction tests, there is no difference in the effect of telmisartan in hypertensive and nonhypertensive patients, suggesting that telmisartan might also reduce the new onset of microalbuminuria and macroalbuminuria in nonhypertensive patients.
Barnett et al. <sup>58</sup> (2004) DETAIL  Enalapril 20 mg/day  vs  telmisartan 80	DB, MC, PG, RCT  Patients aged 35 to 80 years with type 2 diabetes and HTN	N=250  5 years	Primary: Change in the GFR  Secondary: Annual changes in GFR, serum creatinine level, urinary albumin excretion, and blood pressure; rates of	Primary: After five years, GFR decreased by 17.9 mL/minute/1.73 m <sup>2</sup> with telmisartan compared to 14.9 mL/min/1.73 m <sup>2</sup> with enalapril (mean difference, -3.0 mL/min/1.73 m <sup>2</sup> ; 95% CI, -7.6 to 1.6). Therefore, the changes in GFR were comparable between the groups.  Secondary: The effects of the two agents on the secondary end points were not significantly different after five years.

mg/day			ESRD and cardiovascular events; all-cause mortality	
Galle et al. <sup>59</sup> (2008)  Telmisartan 80 mg QD  vs  valsartan 160 mg QD  Additional antihypertensive therapy was allowed.	DB, MC, PG, PRO, RCT, non-inferiority study  Hypertensive patients (SBP/DBP >130/80 mm Hg) with type 2 diabetes, proteinuria and serum creatinine ≤3.0 mg/dL	N=885  12 months	Primary: Change from baseline in the 24-hour proteinuria  Secondary: Changes in 24-hour albuminuria, eGFR and inflammatory parameters	Primary: Telmisartan and valsartan produced comparable reductions in 24-hour urinary protein excretion rates: geometric mean reduction was 33% for both telmisartan and valsartan.  Secondary: No significant differences between treatments were seen in changes from baseline in 24-hour urinary albumin excretion rate and GFR at 12 months.  With both treatments, greater renoprotection was seen among patients with better blood pressure control.  No significant changes in C-reactive protein were noted for either group at 12 months.
Fogari et al. <sup>60</sup> (2007)  Telmisartan and amlodipine 40 to 160-2.5 QD (fixed-dose combination)  vs  telmisartan and amlodipine 40-2.5 mg QD (fixed-dose combination)	DB, MC, RCT  Patients 35 to 70 years of age with essential HTN, type 2 diabetes mellitus and microalbuminuria (UAER >30 and <300 mg/24 hr)	N=210  64 weeks	Primary: Blood pressure, UAER, creatinine clearance, plasma potassium, fasting glycemia, and HbA <sub>1c</sub>  Secondary: Not reported	Primary: High-dose telmisartan/low-dose amlodipine and low-dose telmisartan/high-dose amlodipine combination produced a similar reduction in SBP and DBP with no significant difference between the two regimens at any time of the study.  With increasing doses of telmisartan (40, 80, 120, and 160 mg), SBP and DBP values were reduced from baseline by 16 and 10 mm Hg, respectively (P<0.01), 24 and 21 mm Hg, respectively (P<0.001), 23 and 21 mm Hg, respectively (P<0.001), and 24 and 21 mm Hg, respectively (P<0.001).  With increasing dose of amlodipine (2.5, 5, 7.5, and 10 mg) SBP and DBP values were reduced from baseline by 16 and 10 mm Hg, respectively (P<0.01), 25 and 22 mm Hg, respectively (P<0.001), 25 and 21 mm Hg, respectively (P<0.001), and 25 and 22 mm Hg, respectively (P<0.001).  Reductions of UAER from baseline were of 34.6 mg/24 hr (P<0.05 vs baseline), 62.9 mg/24 hr (P<0.01 vs baseline and P<0.05 vs A group), 86.5

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>mg/24 hr (P&lt;0.001 vs baseline and P&lt;0.01 vs A group) and 102 mg/24 hr (P&lt;0.0001 vs baseline and P&lt;0.001 vs A group) for telmisartan 40, 80, 120, and 160 mg/amlodipine 2.5 mg daily, respectively.</p> <p>Reductions of UAER from baseline were of 35.1 mg/24 hr (P&lt;0.05 vs baseline), 46.2 mg/24 hr (P&lt;0.03 vs baseline), 50.3 mg/24 hr (P&lt;0.03 vs baseline), and 45 mg/24 hr (P&lt;0.03 vs baseline) for amlodipine-telmisartan 2.5-40, 5-40, 7.5-40, and 10-40 mg/day, respectively.</p> <p>Creatinine clearance did not significantly change with either treatment. Neither combination affected levels of plasma potassium or fasting glucose. The HbA<sub>1c</sub> levels were not significantly influenced by either treatment.</p>
<p>Viberti et al.<sup>61</sup> (2002) MARVAL</p> <p>Valsartan 80 mg QD</p> <p>vs</p> <p>amlodipine 5 mg QD</p> <p>A target blood pressure of 135/85 mm Hg was aimed for by dose-doubling followed by the addition of bendrofluazide* and doxazosin whenever needed.</p>	<p>AC, DB, RCT</p> <p>Patients 35-75 years old with type 2 diabetes mellitus and microalbuminuria, with or without HTN</p>	<p>N=332</p> <p>24 weeks</p>	<p>Primary: Change in UAER; proportion of patients who returned to normal albuminuria</p> <p>Secondary: Proportion of patients returning to normoalbuminuria</p>	<p>Primary: Valsartan resulted in a UAER reduction of 44% at 24 weeks compared to baseline vs an 8% reduction with amlodipine (P&lt;0.001). Valsartan lowered UAER similarly in both the hypertensive and normotensive groups.</p> <p>Over the study period, blood pressure reductions were similar between the two treatments and at no time point was there a between-group significant difference in blood pressure values in either the hypertensive or the normotensive subgroup.</p> <p>Secondary: The proportion of patients returning to normal albuminuria was greater with valsartan (29.9%) vs amlodipine (14.5%; P=0.001).</p>
<p>Casas et al.<sup>62</sup> (2005)</p> <p>ACE inhibitor or</p>	<p>MA (127 trials)</p> <p>Studies in adults that examined the effect</p>	<p>N=not reported</p> <p>4.2 years</p>	<p>Primary: Doubling of serum creatinine, and ESRD</p>	<p>Primary: Treatment with ACE inhibitors or ARBs resulted in a nonsignificant reduction in the risk of doubling of creatinine vs other antihypertensives (P=0.07) with no differences in the degree of change of SBP or DBP between the groups.</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>ARBs compared to placebo</p> <p>vs</p> <p>ACE inhibitor or ARBs compared to other antihypertensive drugs (<math>\beta</math>-adrenergic blocking agents, <math>\alpha</math>-adrenergic blocking agents, calcium-channel blocking agents, or combinations)</p> <p>Specific agents and doses were not specified.</p>	<p>of any drug treatment with a blood pressure lowering action on progression of renal disease</p>	<p>(mean)</p>	<p>Secondary: Serum creatinine, urine albumin excretion and GFR</p>	<p>A small reduction in ESRD was observed in patients receiving ACE inhibitors or ARBs compared to other antihypertensives (P=0.04) with no differences in the degree of change of SBP or DBP between the groups.</p> <p>Secondary: Small reductions in serum creatinine and in SBP were noted when ACE inhibitors or ARBs were compared to other antihypertensives (P=0.01).</p> <p>Small reduction in daily urinary albumin excretion in favor of ACE inhibitor or ARBs were reported when these agents were compared to other antihypertensives (P=0.001).</p> <p>Compared to other drugs, ACE inhibitors or ARBs had no effect on the GFR.</p>
<p>Strippoli et al.<sup>63</sup> (2004)</p> <p>ACE inhibitors</p> <p>vs</p> <p>placebo</p> <p>or</p> <p>ARBs</p> <p>vs</p> <p>placebo</p>	<p>MA</p> <p>Patients with diabetic nephropathy</p>	<p>43 trials</p> <p><math>\geq 6</math> months (range 6 to 63.6 months)</p>	<p>Primary: All-cause mortality, renal outcomes (ESRD, doubling of serum creatinine, microalbuminuria to macroalbuminuria)</p> <p>Secondary: Not reported</p>	<p>Primary: ACE inhibitors significantly reduced all-cause mortality compared to placebo or no treatment (RR, 0.79; 95% CI, 0.63 to 0.99; P=0.04). There was a nonsignificant trend for reduction in ESRD (P=0.07) and doubling of serum creatinine (P=0.08) with ACE inhibitors compared to placebo or no treatment. ACE inhibitors significantly reduced the risk of progression from microalbuminuria to macroalbuminuria (P=0.0007) and increased regression back to normoalbuminuria (P&lt;0.0001) compared to placebo or no treatment.</p> <p>ARBs did not significantly reduce all-cause mortality compared to placebo or no treatment (RR, 0.99; 95% CI, 0.85 to 1.17; P=0.95). ARBs significantly reduced the risk of ESRD (P=0.001) and doubling of serum creatinine (P=0.004). ARBs significantly decreased the risk of progression to macroalbuminuria (P=0.001) and increased regression to normoalbuminuria (P=0.02) compared to placebo or no treatment.</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>or ACE inhibitors vs ARBs</p>				<p>The three trials that compared ACE inhibitors to ARBs did not report on all-cause mortality, ESRD or doubling of serum creatinine. Progression from microalbuminuria to macroalbuminuria was reported in one trial (N=92) and there was no significant difference in risk, with the point estimate favoring ACE inhibitors (RR, 0.16; 95% CI, 0.02 to 1.44). Regression from microalbuminuria to normoalbuminuria in 1 trial showed a nonsignificant difference in the risk.</p> <p>Secondary: Not reported</p>
<p>Strippoli et al.<sup>64</sup> (2006) ACE inhibitors vs placebo or ARBs vs placebo or ACE inhibitors vs ARBs</p>	<p>MA  Patients with diabetic kidney disease</p>	<p>N=12,067 (49 trials)  ≥6 months</p>	<p>Primary: All-cause mortality, ESRD, doubling of serum creatinine concentration, progression from micro- to macroalbuminuria, regression from micro- to normoalbuminuria, drug-related toxicity (including cough, headache, hyperkalemia, impotence and pedal edema)</p> <p>Secondary: Not reported</p>	<p>Primary: There was no significant difference in the risk of all-cause mortality for ACE inhibitors vs placebo or no treatment (RR, 0.91; 95% CI, 0.71 to 1.17) and ARBs vs placebo or no treatment (RR, 0.99; 95% CI, 0.85 to 1.17). No statistically significant reduction in the risk of all-cause mortality was found in the three studies that compared ACE inhibitors with ARBs (RR, 0.92; 95% CI, 0.31 to 2.78).</p> <p>A subgroup analysis of studies showed a significant reduction in the risk of all-cause mortality with the use of full-dose ACE inhibitors (RR, 0.78; 95% CI, 0.61 to 0.98) but not when using half or less than half the maximum tolerable dose of ACE inhibitors (RR, 1.18; 95% CI, 0.41 to 3.44).</p> <p>There was a significant reduction in the risk of ESRD with ACE inhibitors and ARBS compared to placebo or no treatment (RR, 0.60; 95% CI, 0.39 to 0.93 and RR, 0.78; 95% CI, 0.67 to 0.91, respectively). There was a significant reduction in the risk of doubling of serum creatinine concentration with ACE inhibitors and ARBS (RR, 0.68; 95% CI, 0.47 to 10 and RR, 0.79; 95% CI, 0.67 to 0.93, respectively).</p> <p>ACE inhibitors and ARBS significantly reduced the risk of progression from micro- to macroalbuminuria (RR, 0.45; 95% CI, 0.29 to 0.69 and RR, 0.49; 95% CI, 0.32 to 0.75, respectively). ACE inhibitors and ARBS significantly increased the regression from micro- to normoalbuminuria compared to placebo or no treatment (RR, 3.06; 95% CI, 1.76 to 5.35 and RR, 1.42; 95% CI, 1.15 to 1.93, respectively).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>The seven studies that compared ACE inhibitors to ARBS did not report the outcome of ESRD or doubling of serum creatinine. Progression from micro- to macroalbuminuria and from micro- to normoalbuminuria were evaluated each in one trial and showed a nonsignificant difference in the risk between ACE inhibitors and ARBS.</p> <p>ACE inhibitors were associated with a significant increase in the risk of cough but not hyperkalemia, headache or impotence when compared to placebo or no treatment. ARBS were associated with a significant increase in the risk of hyperkalemia but not cough or headache compared to placebo or no treatment.</p> <p>Secondary: Not reported</p>
<b>Heart Failure</b>				
<p>Cohn et al.<sup>65</sup> (2001) Val-HeFT  Valsartan 160 mg BID  vs  placebo</p>	<p>DB, PC, RCT  Patients ≥18 years old with a cardiovascular history and NYHA II to IV heart failure</p>	<p>N=5,010  2 years</p>	<p>Primary: Mortality and composite end point of morbidity and mortality  Secondary: Change in NYHA class, ejection fraction, signs and symptoms of heart failure, QOL</p>	<p>Primary: Compared to placebo, valsartan resulted in no significant differences in all-cause mortality.  Patients treated with valsartan experienced a 13% decrease in the composite end point (P=0.009) and 27% decrease in heart failure hospitalizations (P&lt;0.001).  Secondary: Treatment with valsartan resulted in significant improvements in NYHA class, ejection fraction, signs and symptoms of heart failure and QOL as compared to placebo (P&lt;0.01).  In a post hoc analysis of the combined end point and mortality in subgroups defined according to baseline treatments with ACE inhibitors or β-blockers, valsartan had a favorable effect in patients receiving neither or one of these types of drugs but an adverse effect in patients receiving both types of drugs.</p>
<p>Pfeffer et al.<sup>66</sup> (2003) CHARM Overall Programme  Candesartan 32</p>	<p>DB, PC, PG, RCT  Summary of all CHARM sub-studies</p>	<p>N=7,599  37.7 months</p>	<p>Primary: All-cause mortality (Overall Programme) and cardiovascular death or hospital</p>	<p>Primary: In the overall analysis, candesartan 32 mg daily resulted in an 18% decreased risk of all-cause mortality compared to placebo (23 vs 25%; unadjusted HR, 0.91; 95% CI, 0.83 to 1.0; P=0.055; covariate adjusted HR, 0.90; 95% CI, 0.82 to 0.99; P=0.032).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
mg/day ( $\pm$ ACE inhibitor)  vs  placebo ( $\pm$ ACE inhibitor)			admission for CHF (all of the component trials)  Secondary: Not reported	Annual mortality rates were 8.1 and 8.8% for patients treated with candesartan and placebo, respectively.  The lower mortality in patients treated with candesartan vs placebo was attributed to fewer cardiovascular deaths (18 vs 20%; unadjusted HR, 0.88; 95% CI, 0.79 to 0.97; P=0.012).  Hospital admissions for CHF were significantly fewer in patients treated with candesartan than placebo (20 vs 24%; P<0.0001).  Secondary: Not reported
McMurray et al. <sup>67</sup> (2003) CHARM-Added  Candesartan 32 mg/day in patients already taking ACE inhibitors  vs  placebo in patients already taking ACE inhibitors	DB, MC, PC, RCT  Patients $\geq$ 18 years old with LVEF $\leq$ 40%, NYHA II to IV heart failure and treatment with an ACE inhibitor at a constant dose for 30 days or longer	N=2,548  41 months	Primary: Composite of cardiovascular death and hospitalization for heart failure  Secondary: Composites of primary end point and MI, nonfatal stroke and coronary revascularization	Primary: Compared to placebo, candesartan 32 mg/day when added to ACE inhibitors resulted in a 15% reduction in the primary end point (P=0.011), 16% decrease in cardiovascular deaths (P=0.029) and 17% reduction in heart failure hospitalizations (P=0.014).  Secondary: Fewer patients experienced cardiovascular death, hospital admission for CHF, MI, stroke, or coronary revascularization in the candesartan group (42.9%) compared to placebo (46.9%; P=0.015).
Granger et al. <sup>68</sup> (2003) CHARM-Alternative  Candesartan 32 mg/day  vs  placebo	DB, PC, RCT  Patients $\geq$ 18 years old with LVEF $\leq$ 40%, NYHA II to IV heart failure and intolerance to ACE inhibitors	N=2,028  33.7 months	Primary: Composite of cardiovascular death and hospitalization for heart failure  Secondary: Composites of primary end point and MI, nonfatal stroke and coronary	Primary: Compared to placebo, candesartan 32 mg/day resulted in a 30% reduction of the composite end point (P<0.0001).  A 20% decrease in cardiovascular death (P=0.02) and 39% reduction in heart failure hospitalizations (P<0.0001) were noted in patients treated with candesartan compared to placebo.  Study drug discontinuation rates were similar in the candesartan (30%) and placebo (29%) groups.

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
			revascularization	Secondary: Fewer patients experienced cardiovascular death, hospital admission for CHF, MI, stroke, or coronary revascularization in the candesartan group (39.1%) compared to placebo (44.9%; P<0.0001).
Yusuf et al. <sup>69</sup> (2003) CHARM-Preserved  Candesartan 32 mg/day  vs  placebo	DB, PC, RCT  Patients ≥18 years old with preserved ejection fraction (>40%) and symptomatic heart failure	N=3,025  36.6 months	Primary: Composite of cardiovascular death and hospitalization for heart failure  Secondary: Composites of primary end point and MI, nonfatal stroke and coronary revascularization	Primary: Compared to placebo, candesartan 32 mg/day resulted in an insignificant 14% trend towards lower incidence of the primary end point (P=0.051).  Candesartan significantly reduced the risk of heart failure hospitalization (16%; P=0.047) but did not significantly decrease the risk of cardiovascular death (P=0.635).  Secondary: The composite of cardiovascular death, hospitalization for CHF, MI, and stroke was significantly lower in the candesartan group compared to placebo (25.6 vs 28.4%; P=0.037).  There was no significant difference in the composite of cardiovascular death, hospital admission for CHF, MI, stroke, or coronary revascularization in the candesartan group (30.4%) compared to placebo (32.9%; P=0.130).
Castagno et al. <sup>70</sup> (2012) CHARM  Candesartan 32 mg/day (±ACE inhibitor)  vs  placebo (±ACE inhibitor)	Subgroup analysis according to baseline heart rate and LVEF  Patients with chronic heart failure	N=7,597  Duration varied	Primary: Composite of cardiovascular death or heart failure hospital stay  Secondary: Not reported	Primary: Patients with the highest heart rate tertile had worse outcomes when compared to patients in the lowest heart rate group (HR, 1.23; 95% CI, 1.11 to 1.36; P<0.001). The relationship between heart rate and outcomes was similar across LVEF categories, and was not influenced by use of β-blockers (P>0.10 for both endpoints).  Secondary: Not reported
Pitt et al. <sup>71</sup> (1997) ELITE  Captopril 50 mg	DB, MC, PG, RCT  Patients ≥65 years with symptomatic heart failure (NYHA	N=722  1 year	Primary: Change in renal function  Secondary:	Primary: No difference between losartan and captopril was reported in the rate of persistent rise in serum creatinine concentrations (10.5% for both groups).  Secondary:

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
TID vs losartan 50 mg QD	class II to IV and LVEF $\leq$ 40%), and no history of prior ACE inhibitor therapy		Composite of death and/or hospital admission for heart failure, all-cause mortality, admission for heart failure, NYHA class, admission for MI or unstable angina	Death and/or hospital admission for heart failure was recorded in 9.4% of patients receiving losartan and 13.2% for patients receiving captopril (risk reduction, 32%; 95% CI, -4 to 55; P=0.075). This risk reduction was primarily due to a decrease in all-cause mortality (4.8 vs 8.7%; risk reduction, 46%; 95% CI, 5 to 69; P=0.035).  Admissions with heart failure were the same in both groups (5.7%), as was improvement in NYHA functional class from baseline. Admission to hospital for any reason was less frequent with losartan than with captopril treatment (22.2 vs 29.7%; P=0.014).  More patients discontinued therapy due to adverse events with captopril (20.8%) than losartan (12.2%; P=0.002).
Pitt et al. <sup>72</sup> (2000) ELITE II  Captopril 50 mg TID vs losartan 50 mg QD	DB, MC, PG, RCT  Patients $\geq$ 60 years old with symptomatic heart failure (NYHA II to IV and LVEF $\leq$ 40%), and no history of prior ACE inhibitor therapy	N=3,152  555 days (mean follow-up)	Primary: All-cause mortality  Secondary: Composite of sudden cardiac death or resuscitated cardiac arrest	Primary: No significant difference in all-cause mortality was reported between losartan (17.7%) and captopril (15.9%; HR, 1.13; 95% CI, 0.95 to 1.35; P=0.16).  Secondary: Sudden death or resuscitated cardiac arrest was observed in 9.0% of patients receiving losartan and 7.3% of patients receiving captopril (HR, 1.25; 95% CI, 0.98 to 1.60; P=0.08).  Significantly fewer patients in the losartan group (excluding those who died) discontinued study treatment because of adverse events (9.7 vs 14.7%; P<0.001), including cough (0.3 vs 2.7%).  Note: ELITE II trial was a larger follow-up trial to the ELITE I trial to confirm the secondary end point from the ELITE I trial, which reported a greater reduction in all-cause mortality with losartan compared to captopril.
McKelvie et al. <sup>73</sup> (1999) RESOLVD  Enalapril 10 mg BID vs	DB, MC, PG, RCT  Patients with CHF (NYHA classes II to IV), a 6 minute walk distance of 500 meters or less, and an ejection fraction	N=768  43 weeks	Primary: Change in 6-minute walk distance  Secondary: Change in NYHA functional class, QOL, ejection	Primary: There were no significant differences among the groups with regards to the 6-minute walk distance over the 43 week study period.  Secondary: There were no significant differences among the groups with regards to the NYHA functional class or QOL at 18 or 43 weeks.

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>candesartan 4 to 16 mg QD</p> <p>vs</p> <p>candesartan 4 to 8 mg QD and enalapril 10 mg BID</p>	<p>&lt;40%</p>		<p>fraction, ventricular volumes, neurohormone levels, safety</p>	<p>Ejection fraction increased more with candesartan plus enalapril than monotherapy with either agent; however, the difference was not statistically significant (P value not significant). End-diastolic volumes (P&lt;0.01) and end-systolic volumes (P&lt;0.05) increased less with combination therapy than with monotherapy with either agent.</p> <p>Aldosterone decreased with combination therapy at 17 but not 43 weeks compared to candesartan or enalapril (P&lt;0.05). Brain natriuretic peptide decreased with combination therapy compared to candesartan and enalapril alone (P&lt;0.01).</p> <p>Blood pressure decreased with combination therapy compared to candesartan or enalapril alone (P&lt;0.05).</p> <p>Compared to enalapril, potassium decreased with candesartan use (P&lt;0.05) and increased with candesartan plus enalapril (P&lt;0.05). The proportion of patients with potassium levels <math>\geq 5.5</math> mmol/L was not significantly different among the treatment groups. There were no significant differences in creatinine, mortality, or hospitalizations for CHF or any cause among the three groups.</p>
<p>Lee et al.<sup>74</sup> (2004)</p> <p>ARBs</p> <p>vs</p> <p>placebo (<math>\pm</math>ACE inhibitor)</p> <p>vs</p> <p>ACE inhibitor monotherapy</p>	<p>MA</p> <p>Patients with chronic heart failure and high-risk acute MI</p>	<p>N=38,080</p> <p>Duration varied</p>	<p>Primary: All-cause mortality and heart failure hospitalizations</p> <p>Secondary: Not reported</p>	<p>Primary: ARBs were associated with reduced all-cause mortality (OR, 0.83) and heart failure hospitalizations (OR, 0.64) vs placebo.</p> <p>There was no difference in all-cause mortality (OR, 1.06) and heart failure hospitalization (OR, 0.95) between ARBs and ACE inhibitors.</p> <p>When ARBs were combined with ACE inhibitors, all-cause mortality was not reduced (OR, 0.97) but heart failure hospitalizations were reduced (OR, 0.77) compared to treatment with ACE inhibitors alone.</p> <p>Two RCT comparing ARBs with ACE inhibitors in patients with high-risk acute MI did not reveal differences in all-cause mortality or heart failure hospitalization.</p> <p>Secondary: Not reported</p>

combination product)				
Bönnner et al. <sup>78</sup> (2013)  Azilsartan (AZL) 20mg titrated to 40 mg  vs  azilsartan (AZL) 20mg titrated to 80 mg  vs  ramipril (RAM) 2.5 mg titrated to 10 mg	DB, RCT  Patients ≥18 years of age with clinic systolic blood pressure (SBP) 150 to 180 mm Hg	N=884  24 weeks	Primary: Change in trough, seated clinic SBP  Secondary: Change from baseline to week 24 in trough, seated clinic DBP, measures of ambulatory BP, and BP response rates	Primary: After 24 weeks of treatment, trough, sitting, clinic SBP decreased significantly in all the groups. The changes from baseline were significantly greater for the AZL 40 and 80 mg treatment groups (-20.6±0.95 and -21.2±0.95 mm Hg, respectively) than for RAM 10 mg (-12.2±0.95 mm Hg). The differences between the AZL-treated subjects and the RAM-treated subjects were -8.4 mm Hg for AZL 40 and -9.0 mm Hg for AZL 80 (P<0.001 for both comparisons).  Secondary: Change in trough, sitting, DBP was -10.2±0.55 mm Hg in the AZL 40 mg group, -10.5±0.55 mm Hg in the AZL 80 mg and -4.9±0.56 mm Hg in the RAM 10 mg group.  AZL 40 and 80 mg reduced ambulatory SBP and DBP significantly more than RAM for all ABPM time intervals evaluated, including 24-hour mean, mean daytime, mean nighttime and mean trough pressure.  The differences between the AZL and RAM groups proportion of subjects achieving SBP and DBP response criteria were highly significant (P<0.001). More subjects achieved a reduction in clinic BP to <140/90 mm Hg and/or a reduction in BP≥20/10 mm Hg at week 24 following treatment with AZL compared with RAM (54.0% and 53.6% for AZL 40 and 80 mg vs 33.8% with RAM 10 mg, respectively; P<0.001).
Handley et al. <sup>79</sup> (2016)  All subjects initiated treatment with azilsartan 40 mg QD on day one, which was added to existing treatments (a maximum of two	MC, OL, cohort  Patients >18 years of age with essential HTN	N=669  56 weeks	Primary: Safety and tolerability  Secondary: Efficacy	Primary: Approximately 76% of subjects overall in the two cohorts experienced an adverse event. Within each cohort, more events were reported among subjects who received add-on therapy with chlorthalidone or HCTZ. The most commonly reported adverse events (≥5% of subjects) in both cohorts combined, regardless of add-on diuretic therapy, were dizziness (14.3%), headache (9.9%), fatigue (7.2%), upper respiratory tract infection (6.7%) and urinary tract infection (5.7%). Transient serum creatinine elevations were more frequent with add-on chlorthalidone.  Secondary:

Candesartan and HCTZ 32-12.5 or 32-25 mg QD (fixed-dose combination)	≥18 years of age with uncontrolled HTN, on prior antihypertensive agents, and presence of additional cardiovascular risk factors		pressure and ambulatory blood pressure, safety  Secondary: Not reported	Reductions in blood pressure were comparable irrespective of prior or concurrent medications.  Baseline ambulatory blood pressure was 158.2/93.7 mm Hg during the day and 141.8/85.2 mm Hg during the night. After ten weeks, ambulatory blood pressure reduced to 133.6/80.0 and 121.0/72.3 mm Hg, respectively.  During the trial, 49 adverse events were reported in 1.19% of patients receiving combination therapy. Of these events, seven were regarded as serious, and most of the events were related to the nervous system or cardiac disorders.  Secondary: Not reported
McInnes et al. <sup>87</sup> (2000)  Candesartan and HCTZ 8-12.5 mg/day (fixed-dose combination product)  vs  lisinopril and HCTZ 10-12.5 mg/day (fixed-dose combination product)	DB, DD, MC, PG, RCT  Patients 20 to 80 years of age with mild-to-moderate HTN on prior antihypertensive monotherapy	N=355  26 weeks	Primary: Mean changes in DBP  Secondary: Mean changes in SBP and heart rate, proportion of responders and controlled patients, safety	Primary: Changes in mean sitting DBP did not differ significantly between the groups (mean difference, 0.5 mm Hg; P=0.20).  Secondary: No significant differences between the groups were reported for mean sitting SBP, heart rate, proportion of responders and controlled patients.  Both regimens were well tolerated but a greater percentage of those in the lisinopril based group (80 vs 69%) had a least one side effect (P=0.020). The proportion of patients spontaneously reporting cough (23.1 vs 4.6%) and discontinuing therapy due to adverse events (12.0 vs 5.9%) was also higher in the lisinopril based group compared to the candesartan based group.
Hosaka et al. <sup>88</sup> (2015)  Candesartan 8 mg/HCTZ 6.25 mg single pill combination QD	MC, OL, PRO, RCT  Patients, 20 to 80 years old, with newly diagnosed, untreated hypertensive	N=206  8 weeks	Primary: Difference in home morning SBP reduction  Secondary: Time-dependent	Primary: The home BP reduction at eight weeks after randomization was 11.4±1.3 mm Hg for SBP and 5.3±0.7 mm Hg for DBP in the combination group and 7.8±1.2 mm Hg for SBP and 3.6±0.6 mm Hg for DBP in the maximum dose group. Analyses using analysis of covariance adjusted by baseline home BP values as covariates showed that the combination regimen provided additional reductions of 4.0 mm Hg (95% CI, 0.8 to 7.2 mm Hg) for SBP and 1.8 mm Hg

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>vs candesartan 12 mg</p>	<p>patients or those who were on monotherapy with any antihypertensive drug alone</p>		<p>changes in the antihypertensive effects and nocturnal BP reduction</p>	<p>(95% CI, -0.02 to 3.7 mm Hg) for DBP over the maximum dose regimen at four weeks after randomization, whereas at eight weeks after randomization, these reductions were 4.0 mm Hg (95% CI, 0.9 to 7.2 mm Hg) and 1.7 mm Hg (95% CI, -0.05 to 3.4 mm Hg), respectively.</p> <p>Secondary: For home nocturnal BP, the analysis included the 53 patients who measured nocturnal BP at baseline, four and eight weeks after randomization. The reduction in home nocturnal BP at eight weeks after randomization was not different between the two regimen groups.</p> <p>The maximal antihypertensive effect and stabilization time for home SBP were 9.4 mm Hg and 37.1 days (P&lt;0.0001), respectively, with the combination regimen. The maximum dose regimen decreased home SBP with a very gentle slope, and estimated maximal effect and estimated stabilization time were not significant (P&gt;0.2). The rate of achieving target BP (home morning SBP &lt;135 mm Hg) was significantly higher with the combination regimen than with the maximum dose regimen (52.4 vs 30.1%, P=0.002).</p>
<p>Fogari et al.<sup>89</sup> (2007) CANDIA  Candesartan 16 mg and HCTZ 12.5 mg QD  vs  amlodipine 10 mg QD</p>	<p>DB, MC, RCT  Patients, 20 to 80 years old, with mild to moderate uncomplicated HTN not controlled on monotherapy with an antihypertensive (SBP &lt;180 mg Hg and DBP 90 to 110 mg Hg)</p>	<p>N=203  8 weeks</p>	<p>Primary: Decrease in DBP  Secondary: Sitting SBP, reduction of the orthostatic blood pressure at least two minutes after standing, change in heart rate, percentage of patients normalized (DBP &lt;90 mm Hg and SBP &lt;140 mm Hg), percentage of responders (reduction in DBP ≥5 mm Hg)</p>	<p>Primary: There was no significant difference in the mean decrease in DBP between treatment groups; the difference in final DBP was -0.02 mm Hg (95% CI, -1.48 to 1.52 mm Hg; P=0.979).</p> <p>Secondary: There was no significant difference between the groups at week eight for the following: sitting SBP (P=0.835), heart rate (P&lt;0.500), orthostatic SBP (P=0.883), orthostatic DBP (P=0.264), percentage of patients normalized (P=10), percentage of responders (P=0.900).</p> <p>The number of patients reporting an adverse event was greater in the amlodipine group (P=0.001).</p> <p>The number of patients reporting an adverse drug-related event was greater in the amlodipine group (P&lt;0.001).</p> <p>Changes in blood chemistry and other secondary measurements were not significantly different between the treatment groups.</p>

Maeda et al. <sup>113</sup> (2012) ARCH  Losartan and HCTZ (fixed-dose combination product)	MC, OL, OS, PRO  Patients 20 to 80 years of age with HTN uncontrolled by either ARB monotherapy or combination with and ARB and a calcium channel blocker	N=614  52 weeks	Primary: Change in blood pressure at 3 months  Secondary: Not reported	Primary: Blood pressure decreased significantly to 138.0/78.2 mm Hg by month three (P<0.001), and 36.2% of patients were able to achieve target blood pressure (P<0.05).  The hypotensive effect lasted for one year (P<0.001) and was found equally in patients receiving losartan-HCTZ and losartan-HCTZ plus a calcium channel blocker.  Secondary: Not reported
Ueda et al. <sup>114</sup> (abstract) (2012) MAPPY  Losartan and HCTZ 50-12.5 mg QD (fixed-dose combination product)  vs  losartan 100 mg QD	MC, OL, PG, PRO, RCT  Patients with morning HTN	N=216  Duration not specified	Primary: Change in baseline SBP, blood pressure control rate  Secondary: Safety	Primary: Morning SBP was reduced from 150.3±10.1 to 131.5±11.5 mm Hg with combination therapy (P<0.001) and from 151.0±9.3 to 142.5±13.6 mm Hg with high dose losartan therapy (P<0.001). The morning SBP reduction was significantly greater with combination therapy group compared to high dose losartan therapy (P<0.001).  Combination therapy decreased evening SBP from 141.6±13.3 to 125.3±13.1 mm Hg (P<0.001), and high dose losartan therapy decreased evening SBP from 138.9±9.9 to 131.4±13.2 mm Hg (P<0.01).  Although both therapies improved target blood pressure achievement rates in the morning and evening (P<0.001 for both), combination therapy significantly increased the achievement rates compared to high dose losartan therapy (P<0.001 and P<0.05, respectively).  Secondary: Combination therapy decreased urine albumin excretion (P<0.05) whereas high-dose therapy reduced serum uric acid. Both therapies indicated strong adherence and few adverse effects (P<0.001).

mg QD  If blood pressure exceeded 140/90 while on highest treatment dose, HCTZ 12.5mg/day was added to the regimen.			treatment, percent of patients who achieved goal <140/<90 with each treatment based on clinic blood pressure measurements	
Ichihara et al. <sup>144</sup> (2006)  Valsartan 40 to 160 mg QD  vs  amlodipine 2.5 to 10 mg QD	RCT  Patients with untreated HTN (clinic SBP >140 mm Hg and/or DBP >90 mm Hg; or ABPM SBP >135 mm Hg and/or DBP >98 mm Hg)	N=100  12 months	Primary: ABPM and clinic blood pressure  Secondary: Pulse wave velocity, carotid intima-media thickness, urinary albumin excretion	Primary: Both treatments resulted in significant decreases in blood pressure, both ambulatory and clinic, over 12 months from baseline; blood pressure decreases were similar between treatment groups (between treatments: clinic SBP P=0.34; clinic DBP P=0.85; 24 hour ABPM P=0.14).  Blood pressure variability decreased significantly in the amlodipine group compared to the valsartan group, where there was no change in blood pressure variability (P<0.01).  Secondary: The decrease in pulse wave velocity was significant from baseline for both groups, but not significantly different from each other (P<0.05 from baseline).  Intima-media thickness was not changed significantly from baseline for either treatment (P>0.05 for both from baseline).  Urinary albumin excretion in the valsartan group decreased significantly both from baseline and compared to amlodipine treatment (P<0.05 from baseline, P value for comparison not reported).
Flynn et al. <sup>145</sup> (2008)  Phase 1 Valsartan low, medium or high dose (5 mg, 20 mg and 40 mg for <18	DB, MC, RCT  Children one to five years of age with SBP ≥95 <sup>th</sup> percentile for age, gender and height with minimum weight of	N=90  4 weeks (2 weeks of phase 1 and 2 weeks of phase 2)	Primary: Change in mean seated SBP from baseline to end of phase 1 and from end of phase 1 to the end of phase 2	Primary: In phase 1, valsartan significantly lowered SBP in all of the dose groups (SBP: low dose: -8.4 mm Hg; medium dose: -8.3 mm Hg; high dose: -8.6 mm Hg). From the end of phase 1 to the end of phase 2, subjects who remained on valsartan exhibited a mean reduction in seated SBP of -1.5 mm Hg, whereas placebo recipients had a mean increase in SBP of 1.5 mm Hg. The least-squares mean difference in the change in SBP between the pooled valsartan and placebo groups (-3.9 mm Hg) was significant (P=0.02).

Sinkiewicz et al. <sup>149</sup> (2009)  Amlodipine and valsartan 10-160 mg or 5-160 mg QD (fixed-dose combination product)  vs  valsartan 160 mg QD	AC, DB, MC, RCT  Patients ≥18 years of age with essential HTN (mean sitting DBP ≥90 mm Hg and <110 mm Hg) who were inadequately controlled on valsartan 160 mg	N=947  8 weeks	Primary: Change from baseline in mean DBP  Secondary: Change from baseline in mean sitting SBP, responder rate (mean DBP <90 mm Hg or ≥10 mm Hg reduction from baseline), and DBP control rate (mean DBP < 90 mm Hg)	Primary: At week eight, a significantly greater reduction in mean DBP was observed with both amlodipine and valsartan combinations (10-160 mg: -11.5 mm Hg, 5-160 mg: -9.6 mm Hg; P<0.0001 for both) compared to valsartan monotherapy (-6.7 mm Hg).  Secondary: At week eight, a significantly greater reduction in mean SBP was observed in both amlodipine and valsartan combinations (10-160 mg: -14.3 mm Hg, 5-160 mg: -12.2 mm Hg; P<0.0001 for both) compared to valsartan monotherapy (-8.3 mm Hg).  Overall mean SBP/DBP reductions of 22.5/15.5 and 21.3/13.7 mm Hg were observed in the amlodipine and valsartan 10-160 and 5-160 mg treatment groups, respectively compared to 16.7/11.4 mm Hg in the valsartan 160 mg group. The amlodipine and valsartan 10-160 mg combination showed a significantly greater reduction in mean SBP/DBP compared to amlodipine and valsartan 5-160 mg (P<0.001).  Responder rates were higher in both amlodipine and valsartan groups (10-160 mg: 81% [P<0.0001]; 5-160 mg: 68% [P=0.0018], respectively) compared to valsartan monotherapy (57%).  Peripheral edema was the most frequent adverse event, which was reported in 9.1% of patients receiving amlodipine and valsartan (10-160 mg), 0.9% of patients receiving amlodipine and valsartan (5-160 mg), and 1.3% of patients receiving valsartan monotherapy.
Philipp et al (abstract). <sup>150</sup> (2011)	Post-hoc analysis  Patients with HTN	N=834  Not reported	Primary: Rate of blood pressure control	Primary: Two weeks after starting therapy, blood pressure control rates were greater with amlodipine and valsartan 10-320 mg/day (49%) vs monotherapies (32 to

Conlin et al. <sup>165</sup> (2000) PREVAIL  Candesartan 8 to 16 mg QD, irbesartan 150 to 300 mg QD, losartan 50 to 100 mg QD, and valsartan 80 to 160 mg QD  vs  another ARB  vs  ARB plus low-dose HCTZ	MA  Patients with HTN	N=11,281 (43 trials)  Duration varied	Primary: Weighted average for SBP and DBP reduction with ARB monotherapy, dose titration, and with the addition of low-dose HCTZ were calculated; responder rates  Secondary: Not reported	Primary: The absolute weighted-average reductions in DBP (8.2 to 8.9 mm Hg) and SBP (10.4 to 11.8 mm Hg) for ARB monotherapy were comparable for all ARBs. Responder rates for ARB monotherapy were 48 to 55%.  Dose titration resulted in slightly greater blood pressure reductions and an increase in responder rates of 53 to 63%.  ARB and HCTZ combinations produced substantially greater reductions in SBP (16.1 to 20.6 mm Hg) and DBP (9.9 to 13.6 mm Hg) than ARB monotherapy. Responder rates for ARB and HCTZ combinations were 56 to 70%.  The authors concluded that candesartan, irbesartan, losartan, and valsartan produced comparable antihypertensive efficacy when administered at their recommended doses, a near flat dose response when titrating from starting to maximum recommended dose, and substantial potentiation of the antihypertensive effect with addition of HCTZ.  Secondary: Not reported

placebo in addition to conventional therapy (diuretics, ACE inhibitors, $\beta$ -blockers, calcium channel blockers)			fatal stroke and MI	There were no marked or statistically significant differences between the treatment groups in other cardiovascular end points or all-cause mortality.
Ogihara et al. <sup>172</sup> (2008) CASE-J Candesartan 4 to 12 mg QD vs amlodipine 2.5 to 10 mg QD	AC, MC, OL, RCT  Patients with high risk HTN (SBP $\geq 140$ mm Hg or DBP $\geq 90$ mm Hg in patients $< 70$ years old or SBP $\geq 160$ mm Hg or DBP $\geq 90$ mm Hg in patients $\geq 70$ years old), with either type 2 diabetes, history of stroke or ischemic attack, left ventricular hypertrophy, proteinuria or serum creatinine $\geq 1.3$ mg/dL	N=4,703  Up to 4 years	Primary: First fatal or nonfatal cardiovascular event  Secondary: All-cause death, new-onset diabetes, discontinuation due to adverse events	Primary: A total of 134 patients experienced a cardiovascular event in each treatment regimen (HR, 1.0; 95% CI, 0.78 to 1.27; P=0.969).  Secondary: All-cause death rates did not differ between treatments, 73 deaths in the candesartan group and 86 in the amlodipine group.  New-onset diabetes occurred in significantly fewer patients in the candesartan group than the amlodipine group (HR, 0.64; 95% CI, 0.43 to 0.97; P=0.033).  A total of 125 (5.4%) patients in the candesartan group and 134 (5.8%) of patients in the amlodipine group discontinued due to adverse events.
Taniguchi et al. <sup>173</sup> (2006)  Candesartan 8 mg in addition to spironolactone 25 mg QD for 6 months, after 6 months of candesartan monotherapy	DB, RCT, XO  Patients, 67 years of age on average, with essential HTN and left ventricular hypertrophy	N=97  1 year	Primary: Change in blood pressure and relative wall thickness  Secondary: Not reported	Primary: Both study groups experienced a statistically significant reduction in blood pressure from baseline (P<0.05).  While candesartan was associated with a significant reduction in relative wall thickness among patients with concentric left ventricular remodeling or hypertrophy (P<0.05), the addition of spironolactone did not provide additional benefit.  Secondary: Not reported

(combination group)  vs  candesartan 8 mg daily for 12 months				
Montalescot et al. <sup>174</sup> (2009) ARCHIPELAGO  Enalapril 10 mg QD, followed by 20 mg QD on day 15  vs  irbesartan 150 mg QD, followed by 300 mg QD on day 15	AC, DB, MC, RCT  Adults with non-ST elevation ACS	N=429  60 days	Primary: Change from baseline in high-sensitivity C-reactive protein at day 60  Secondary: Changes in other inflammatory markers such as troponin I	Primary: High-sensitivity C-reactive protein levels were comparable in both treatment groups (irbesartan: 15.2 mg/L at baseline, 6.5 mg/L at day 60; absolute change of -8.7 mg/L; enalapril: 12.6 mg/L at baseline, 5.5 mg/L at day 60; absolute change of -7.1 mg/L, P value not significant).  Secondary: Similarly, mean levels of markers of myocardial injury (troponin I) and endothelial dysfunction (microalbuminuria) also decreased from baseline to day 60, with no significant differences between treatment groups.
Solomon et al. <sup>175</sup> (2009) ALLAY  Losartan 100 mg QD  vs  aliskiren 300 mg QD  vs	AC, RCT  Adults with HTN and increased left ventricular wall thickness	N=465  9 months	Primary: Change in left ventricular mass  Secondary: Not reported	Primary: There were reductions in left ventricular mass from baseline in all treatment groups, with 4.9-g/m <sup>2</sup> (5.4%), 4.8-g/m <sup>2</sup> (4.7%), and 5.8-g/m <sup>2</sup> (6.4%) reductions in the aliskiren, losartan, and combination arms, respectively (P<0.0001 for all treatment groups).  The reduction in left ventricular mass in the combination group was not significantly different from that with losartan alone (P=0.52).  The difference in left ventricular mass regression between the aliskiren and losartan arms was within the prespecified non-inferiority margin, suggesting that aliskiren was as effective as losartan in reducing left ventricular hypertrophy (P<0.0001 for non-inferiority).

aliskiren 300 mg and losartan 100 mg QD				Secondary: Not reported
Fliser et al. <sup>176</sup> (2004) EUTOPIA  Olmesartan 20 mg/day  vs  placebo  All patients received pravastatin 20 mg/day after six weeks of therapy.	DB, PC, PG, RCT  Patients ≥18 years old with HTN, atherosclerotic disease, type 2 diabetes mellitus, and/or LDL-C between 3.89 to 6.48 mmol/L	N=199  12 weeks	Primary: Evaluate anti-inflammatory effects of olmesartan using a panel of inflammation markers: high-sensitivity C-reactive protein, high-sensitivity tumor necrosis factor- $\alpha$ , interleukin-6  Secondary: Not reported	Primary: After six weeks of therapy, olmesartan treatment significantly reduced serum levels of C-reactive protein (-15.1%; P<0.05), tumor necrosis factor- $\alpha$ (-8.9%; P<0.02), interleukin-6 (-14.0%; P<0.05) and monocyte chemotactic protein-1 (-6.5%; P<0.01), whereas placebo treatment had no major effect on inflammation markers.  After 12 weeks of therapy, C-reactive protein (-21.1%; P<0.02), tumor necrosis factor- $\alpha$ (-13.6%; P<0.01), and interleukin-6 (-8.0%; P<0.01) decreased further with olmesartan and pravastatin cotherapy, but treatment with pravastatin alone did not significantly alter inflammation markers.  In contrast, addition of pravastatin led to a significant (P<0.001) reduction in LDL-C in the olmesartan and placebo groups (-15.1 and -12.1%, respectively).  Secondary: Not reported
Rosendorff et al. <sup>177</sup> (2009)  Olmesartan 20 to 40 mg QD  vs  amlodipine 5 to 10 mg QD	DB, AC, RCT  Adults with HTN and left ventricular hypertrophy	N=102  52 weeks	Primary: Change in left ventricular mass from baseline to 52 weeks  Secondary: Change in left ventricular mass after 26 weeks of treatment	Primary: Mean±SD left ventricular masses of 252.9±73.06 g in the olmesartan group and 236.9±59.94 g in the amlodipine group at baseline were decreased to 248.2±69.31 and 223.9±53.18 g, respectively, after 52 weeks of therapy. Neither of these changes was significantly different from baseline, and the difference between the two treatment groups was not significant.  Secondary: At 26 weeks, adjusted percent changes in left ventricular mass were 8.0% with olmesartan and 6.0% with amlodipine. Changes occurring at the 26-week assessment were not significantly different from baseline or from each other.
ONTARGET Investigators <sup>178</sup> (2008)  Ramipril 10 mg/day	DB, MC, PC, RCT  Patients with coronary, peripheral, or cerebrovascular disease or diabetes	N=25,620  56 months (median follow-up)	Primary: Death from cardiovascular causes, MI, stroke or hospitalization for heart failure	Primary: The primary outcome occurred in 16.5, 16.7, and 16.3% of patients receiving ramipril, telmisartan and combination therapy, respectively.  Secondary: The composite of death from cardiovascular causes, MI or stroke occurred in

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs  telmisartan 80 mg/day  vs  ramipril 10 mg/day and telmisartan 80 mg/day	with end-organ damage		Secondary: Composite of death from cardiovascular causes, MI or stroke; heart failure, worsening or new angina, new diagnosis diabetes mellitus, new atrial fibrillation, renal impairment, revascularization procedures	<p>14.1% of patients in the ramipril group and 13.9% of patients in the telmisartan group (RR, 0.99; 95% CI, 0.91 to 1.17; P=0.001 for non-inferiority). Combination therapy was not significantly better than ramipril alone (RR, 0.99; 95% CI, 0.92 to 1.07).</p> <p>There were no significant differences in the rates of secondary outcomes, except for renal dysfunction, which occurred in 10.2% of patients receiving ramipril, 10.6% of patients receiving telmisartan and 13.5% of patients receiving combination therapy (P&lt;0.001 vs ramipril; P value not reported vs telmisartan).</p> <p>As compared to the ramipril group, the telmisartan group had lower rates of cough (1.1 vs 4.2%; P&lt;0.001) and angioedema (0.1 vs 0.3%; P=0.01) and a higher rate of hypotensive symptoms (2.6 vs 1.7%; P&lt;0.001); the rate of syncope was the same in the two groups (0.2%).</p> <p>As compared to the ramipril group, combination therapy had an increased risk of hypotensive symptoms (4.8 vs 1.7%; P&lt;0.001), syncope (0.3 vs 0.2%; P=0.03) and renal dysfunction (13.5 vs 10.2%; P&lt;0.001).</p>
Mann et al. <sup>179</sup> (2013) ONTARGET  Ramipril with telmisartan	Subanalysis  Patients in the ONTARGET trial with diabetes mellitus	N=3163 with CKD N=6465 no CKD  56 months	Primary: Composite of death from cardiovascular cause, nonfatal MI, nonfatal stroke or hospitalization for CHF  Secondary: composite renal outcome for this analysis was defined posthoc as chronic dialysis (>2 months) or a doubling of baseline serum creatinine	Primary: The stroke rate in all participants with diabetes was not different between the treatment groups, 1.19 and 1.22 per 100 patient-years in those on dual and monotherapy, respectively (HR, 0.99; 95% CI, 0.82 to 1.20). The results were consistent in those with or without renal disease (P value for interaction =0.60; 1.59 vs 1.55 and 1.01 vs 1.08 strokes per 100 patient-years, respectively). Results for other major outcomes indicated no differences and no interaction of renal subgroups with treatment effects.  Secondary: Dialysis-dependent acute kidney injury tended to occur more frequently in those allocated to dual than with monotherapy, 0.14 vs 0.08 cases per 100 patient-years, (HR, 1.55; 95% CI, 0.84 to 2.85), and hyperkalemia was more frequent, 1.82 vs 1.07 cases per 100 patient-years (HR, 1.71; 95% CI, 1.44 to 2.02). Both adverse outcomes were more frequent in those with renal disease; however, the excess due to dual therapy was similar in those with and without renal disease.

The Navigator Study Group <sup>184</sup> (2010) NAVIGATOR  Valsartan up to 160 mg QD or matching placebo  and  nateglinide or matching placebo	DB, MC, RCT  Adults with impaired glucose tolerance and established cardiovascular disease or cardiovascular risk factors.	N=9,306  5 years	Primary: Incidence of diabetes and a composite of death from cardiovascular causes, nonfatal MI, nonfatal stroke, hospitalization for heart failure, arterial revascularization, or hospitalization for unstable angina  Secondary: Not reported	Primary: The cumulative incidence of diabetes was 33.1% in the valsartan group, as compared to 36.8% in the placebo group (HR in the valsartan group, 0.86; 95% CI, 0.80 to 0.92; P<0.001).  Valsartan, as compared to placebo, did not significantly reduce the incidence of the composite cardiovascular outcome (14.5% vs 14.8%; HR, 0.96; 95% CI, 0.86 to 1.07; P=0.43).  Secondary: Not reported
Blood Pressure Lowering Treatment Trialists' Collaboration <sup>185</sup> (2007)  ACE inhibitors (17 trials)  vs  ARBs (9 trials)	MA  Patients with high blood pressure, diabetes, history or CHD or cerebrovascular disease	N=146,838 (26 trials)  Variable duration	Primary: Nonfatal MI or death from CHD, including sudden death; heart failure causing death or requiring hospitalization; nonfatal stroke or death from cerebrovascular disease  Secondary: Not reported	Primary: From a total of 146,838 individuals with high blood pressure or an elevated risk of cardiovascular disease, major cardiovascular events were documented in 22,666 patients during follow-up. The analyses showed comparable blood pressure-dependent reductions in risk with ACE inhibitors and ARBs (P≥0.3 for all three outcomes).  ACE inhibitors produced a blood pressure-independent reduction in the relative risk of CHD of approximately 9% (95% CI, 3 to 14%). No similar effect was detected for ARBs, and there was some evidence of a difference between ACE inhibitors and ARBs in this regard (P=0.002).  For both stroke and heart failure, there was no evidence of any blood pressure-independent effects of either ACE inhibitors or ARBs.  Secondary: Not reported

\*Agent not available in the United States.

**Additional Evidence**

Dose Simplification

Sung et al. evaluated adherence rates with a triple component single pill regimen of olmesartan 20 mg/amlodipine 5 mg/hydrochlorothiazide 12.5 mg compared to the equivalent two-pill regimen of olmesartan 20 mg/hydrochlorothiazide 12.5 mg plus amlodipine 5 mg for 12 weeks. The single-pill group had significantly higher percentage of doses taken than the two-pill group with median (25 to 75 percentile) of 95.1 (95% confidence interval [CI], 86.7 to 100.0) versus 92.1 (95% CI, 73.0 to 97.3) as well as a significantly higher prescribed dose taken correctly with median (25 to 75 percentile) of 91.0 (95% CI, 79.4 to 96.5) versus 88.6 (95% CI, 69.2 to 96.3), P = 0.04 for both comparisons.<sup>186</sup>

**IX. Cost**

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of '\$' signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

\*Generic is available in at least one dosage form or strength.  
HCTZ=hydrochlorothiazide, N/A=not available

## X. Conclusions

All of the angiotensin II receptor blockers (ARBs) are approved for the treatment of hypertension. Some of the products are also approved for the treatment of diabetic nephropathy (irbesartan and losartan), heart failure (candesartan and valsartan), post-myocardial infarction (valsartan), as well as cardiovascular and cerebrovascular risk reduction (telmisartan and losartan, respectively).<sup>3-20</sup> The ARBs are available as single entity products, and most are also available in combination with hydrochlorothiazide. Azilsartan is available in combination with chlorthalidone, telmisartan is available in combination with amlodipine, and olmesartan is available in combination with amlodipine and hydrochlorothiazide (triple therapy). There are other ARBs that are available in combination with amlodipine (olmesartan and valsartan); however, these products are included in the dihydropyridines class review (AHFS Class 242808). All single entity products with the exception of azilsartan are available generically. Fixed-dose combination products are available in a generic formulation with the exception of azilsartan-chlorthalidone.

National and international guidelines recommend the use of ACE inhibitors or ARBs in patients with cerebrovascular disease, coronary artery disease, heart failure, hypertension, left ventricular dysfunction, left ventricular hypertrophy, diabetes, diabetic nephropathy, previous myocardial infarction, and renal disease.<sup>22-40</sup> In general, guidelines do not give preference to one ARB over another.<sup>22-40</sup> Some of the guidelines specifically recommend the use of ACE inhibitors as initial therapy, with the subsequent use of ARBs in patients who do not tolerate ACE inhibitors.<sup>22,24-31,36</sup> Thiazide-type diuretics are frequently recommended as initial therapy in patients with uncomplicated hypertension.<sup>32-37</sup> According to the National Heart, Lung, and Blood Institute's Eighth Report of The Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 8), thiazide-type diuretics should be utilized first-line for most patients with hypertension, either alone or in combination with another hypertensive from a different medication class (e.g., ACE inhibitors, ARBs,  $\beta$ -blockers, calcium channel blockers).<sup>32</sup> Several guidelines consistently recommend that the selection of an antihypertensive agent be based on compelling indications for use.<sup>32-39</sup> Most patients will require more than one antihypertensive medication to achieve blood pressure goals.<sup>32-36</sup>

Numerous clinical trials have shown that the ARBs can effectively lower systolic and diastolic blood pressure, administered alone or in combination with other antihypertensive agents. Some comparative trials have demonstrated slight differences in blood pressure effects among the various ARBs; however, the clinical significance of these differences remains to be established.<sup>75-170</sup> Guidelines do not give preference to one ARB over another for the treatment of hypertension. Most patients will require more than one antihypertensive agent to achieve blood pressure goals.<sup>32-36</sup> The use of a fixed-dose combination product may simplify the treatment regimen and improve adherence.<sup>34-35,38,186</sup> However, there are no prospective, randomized trials that have demonstrated better clinical outcomes with a fixed-dose combination product compared to the coadministration of the individual components as separate formulations.

ARBs have been shown to reduce cardiovascular morbidity and mortality, as well as preserve renal function.<sup>41-64</sup> The use of losartan also decreases the risk of stroke in patients with hypertension and left ventricular hypertrophy.<sup>6,13</sup> It should be noted that the ACE inhibitors have also been shown to positively impact these endpoints as well (please refer to ACE inhibitor class review for additional information). Several studies comparing ARBs and ACE inhibitors have demonstrated similar efficacy with regards to cardiovascular events, heart failure and the rate of progression of nephropathy.<sup>41,42,44,46,51-55,58,64,66,71-74,178</sup> ACE inhibitors inhibit the

breakdown of bradykinin, which may lead to the development of a persistent non-productive cough. The ARBs do not increase bradykinin and may be better tolerated in some patients.<sup>20,21</sup>

The FDA has evaluated data from two clinical trials (ROADMAP and ORIENT) in which patients with type 2 diabetes who were taking olmesartan had a higher rate of death from cardiovascular causes compared to those who were taking placebo. After the review was completed in April 2011, the FDA has determined that the benefits of olmesartan continue to outweigh its potential risks when used for the treatment of patients with high blood pressure according to the approved drug label. Of note, olmesartan is not recommended as a treatment to delay or prevent protein in the urine in diabetic patients.<sup>187</sup> In June of 2011, the FDA also concluded that a review of a meta-analysis of 31 randomized-controlled trials comparing ARBs to other treatments found no evidence of an increased risk of incident (new) cancer, cancer-related death, breast cancer, lung cancer, or prostate cancer in patients receiving ARBs.<sup>188</sup>

At this time, there is insufficient evidence to conclude that the angiotensin II receptor antagonists offer a significant clinical advantage over other alternatives in general use. Therefore, all brand angiotensin II receptor antagonists within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

## **XI. Recommendations**

No brand angiotensin II receptor antagonist is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

**Alabama Medicaid Agency  
Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Mineralocorticoid (Aldosterone) Receptor Antagonists  
AHFS Class 243220  
May 4, 2022**

**I. Overview**

Aldosterone is a component of the renin-angiotensin-aldosterone (RAAS) system, which is responsible for the regulation of extracellular volume and blood pressure. Upon binding to the mineralocorticoid receptor on the distal renal tubule, aldosterone activates the sodium-potassium exchange pump, leading to sodium and water retention, as well as potassium excretion. Increased levels of aldosterone are present in both primary and secondary hyperaldosteronism. Heart failure, hepatic cirrhosis, and the nephrotic syndrome are edematous conditions, which can lead to secondary aldosteronism. Volume depletion and sodium loss due to diuretic therapy may also cause secondary aldosteronism.<sup>1,2</sup>

The mineralocorticoid (aldosterone) receptor antagonists, eplerenone and spironolactone, are approved for the treatment of edema, heart failure, hypertension, hypokalemia, and primary hyperaldosteronism. Eplerenone and spironolactone bind to mineralocorticoid receptors, which blocks the binding of aldosterone.<sup>1-6</sup> They are available as single entity agents, and spironolactone is also available in combination with hydrochlorothiazide. Hydrochlorothiazide inhibits the reabsorption of sodium and chloride in the cortical thick ascending limb of the loop of Henle and the early distal tubules. This action leads to an increase in the urinary excretion of sodium and chloride.<sup>1,2</sup> Finerenone is a novel, non-steroidal, selective mineralocorticoid receptor antagonist that has shown to reduce albuminuria in type 2 diabetes (T2D) patients with chronic kidney disease (CKD), while revealing only a low risk of hyperkalemia. In contrast to steroidal mineralocorticoid receptor antagonists such as spironolactone, finerenone is more selective for the mineralocorticoid receptor.<sup>7-9</sup>

The mineralocorticoid (aldosterone) receptor antagonists that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. All of the agents except finerenone are available in a generic formulation. This class was last reviewed in February 2020.

**Table 1. Mineralocorticoid (Aldosterone) Receptor Antagonists Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
<b>Single Entity Agents</b>			
Eplerenone	tablet	Inspra®*	eplerenone
Finerenone	tablet	Kerendia®	none
Spironolactone	suspension, tablet	Aldactone®*, Carospir®	spironolactone
<b>Combination Products</b>			
Spironolactone and hydrochlorothiazide	tablet	Aldactazide®*	spironolactone and hydrochlorothiazide

\*Generic is available in at least one dosage form or strength.  
PDL=Preferred Drug List

**II. Evidence-Based Medicine and Current Treatment Guidelines**

Current treatment guidelines that incorporate the use of the mineralocorticoid (aldosterone) receptor antagonists are summarized in Table 2.

**Table 2. Treatment Guidelines Using the Mineralocorticoid (Aldosterone) Receptor Antagonists**

Clinical Guideline	Recommendations
American College of Cardiology/American Heart Association: <b>2007 Chronic Angina Focused Update of</b>	<ul style="list-style-type: none"> <li>Aspirin should be started at 75 to 162 mg/day and continued indefinitely in all patients, unless contraindicated.</li> <li>Use of warfarin in conjunction with aspirin and/or clopidogrel is associated with an increased risk of bleeding and should be monitored closely.</li> </ul>

Clinical Guideline	Recommendations
<p><b>the 2002 Guidelines for the Management of Patients With Chronic Stable Angina (2007)<sup>10</sup></b></p>	<ul style="list-style-type: none"> <li>• Patients with hypertension and established coronary artery disease (CAD) should be treated with blood pressure medication(s) as tolerated, including angiotensin-converting enzyme inhibitors (ACE inhibitors) and/or <math>\beta</math>-adrenergic antagonists (<math>\beta</math>-blockers) with the addition of other medications as needed to achieve blood pressure goals of &lt;140/90 or &lt;130/80 mm Hg for patients with chronic kidney disease or diabetes.</li> <li>• Long-acting calcium-channel blocking agents or long-acting nitrates may be used if <math>\beta</math>-blockers are contraindicated. Immediate-release and short-acting dihydropyridine calcium channel blockers can increase adverse cardiac events and should not be used.</li> <li>• Long-acting calcium channel blockers or long-acting nitrates may be used with <math>\beta</math>-blockers if initial treatment is not successful.</li> <li>• ACE inhibitors should be used indefinitely in patients with a left ventricular ejection fraction (LVEF) of <math>\leq 40\%</math> and in those with hypertension, diabetes or chronic kidney disease, unless contraindicated.</li> <li>• ACE inhibitors should also be used indefinitely in patients at lower risk (mildly reduced or normal LVEF in whom cardiovascular risk factors remain well controlled and revascularization has been performed), unless contraindicated.</li> <li>• Angiotensin II receptor blockers (ARBs) are recommended in patients with hypertension, those who have an indication for an ACE inhibitor and are intolerant to them, who have heart failure, or who have had a myocardial infarction (MI) and have a LVEF of <math>\leq 40\%</math>.</li> <li>• ARBs may be considered in combination with an ACE inhibitor for heart failure due to left ventricular systolic dysfunction.</li> <li>• Aldosterone blockade is recommended in patients post-MI without significant renal dysfunction or hyperkalemia who are already receiving therapeutic doses of an ACE inhibitor and a <math>\beta</math>-blocker, have a LVEF <math>\leq 40\%</math> and have either diabetes or heart failure.</li> <li>• It is beneficial to start and continue <math>\beta</math>-blocker therapy indefinitely in all patients who have had a MI, acute coronary syndrome or left ventricular dysfunction with or without heart failure symptoms, unless contraindicated.</li> <li>• Annual influenza vaccination is recommended in patients with cardiovascular disease.</li> </ul>
<p><b>European Society of Cardiology: Guidelines for the Diagnosis and Management of Chronic Coronary Syndromes (2019)<sup>11</sup></b></p>	<p><b>Pharmacological management of stable coronary artery disease (CAD) patients</b></p> <ul style="list-style-type: none"> <li>• The two aims of the pharmacological management of stable CAD patients are to obtain relief of symptoms and to prevent CV events.</li> <li>• Optimal medical treatment indicates at least one drug for angina/ischemia relief plus drugs for event prevention.</li> <li>• It is recommended to educate patients about the disease, risk factors and treatment strategy.</li> <li>• It is indicated to review the patient's response soon after starting therapy.</li> <li>• Concomitant use of a proton pump inhibitor is recommended in patients receiving aspirin monotherapy, DAPT, or DOAC monotherapy who are at high risk of gastrointestinal bleeding.</li> <li>• Lipid-lowering drugs: if goals are not met on maximum tolerated dose of a statin, consideration of combination therapy with ezetimibe or a PCSK9 inhibitor is recommended</li> <li>• ACE inhibitors should be considered in patients at a very high risk of cardiovascular adverse events</li> <li>• Angina/ischemia relief:             <ul style="list-style-type: none"> <li>○ Short-acting nitrates are recommended.</li> <li>○ First-line treatment is indicated with <math>\beta</math>-blockers and/or calcium channel blockers to control heart rate and symptoms.</li> <li>○ Long-acting nitrates should be considered as a second-line treatment option when initial therapy with a beta-blocker and/or a non-DHP-</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>calcium channel blocker is contraindicated, poorly tolerated, or inadequate in controlling angina symptoms</p> <ul style="list-style-type: none"> <li>○ Nicorandil, ranolazine, ivabradine, or trimetazidine should be considered as a second-line treatment to reduce angina frequency and improve exercise tolerance in subjects who cannot tolerate, have contraindications to, or whose symptoms are not adequately controlled by beta-blockers, CCBs, and long-acting nitrates.</li> <li>○ According to comorbidities/tolerance, it is indicated to use second-line therapies as first-line treatment in selected patients.</li> <li>○ In asymptomatic patients with large areas of ischaemia (&gt;10%) <math>\beta</math>-blockers should be considered.</li> <li>○ In patients with vasospastic angina, calcium channel blockers and nitrates should be considered and beta-blockers avoided.</li> </ul> <ul style="list-style-type: none"> <li>● Event prevention:           <ul style="list-style-type: none"> <li>○ Low-dose aspirin daily is recommended in all stable CAD patients.</li> <li>○ Clopidogrel is indicated as an alternative in case of aspirin intolerance.</li> <li>○ Statins are recommended in all stable CAD patients.</li> <li>○ It is recommended to use ACE inhibitors (or ARBs) if presence of other conditions (e.g., heart failure, hypertension or diabetes).</li> </ul> </li> </ul> <p><u>Treatment in patients with microvascular angina</u></p> <ul style="list-style-type: none"> <li>● It is recommended that all patients receive secondary prevention medications including aspirin and statins.</li> <li>● <math>\beta</math>-blockers are recommended as a first-line treatment.</li> <li>● Calcium antagonists are recommended if <math>\beta</math>-blockers do not achieve sufficient symptomatic benefit or are not tolerated.</li> <li>● ACE inhibitors or nicorandil may be considered in patients with refractory symptoms.</li> <li>● Xanthine derivatives or nonpharmacological treatments such as neurostimulatory techniques may be considered in patients with symptoms refractory to the above listed drugs.</li> </ul> <p><u>Stenting and peri-procedural antiplatelet strategies in stable CAD patients</u></p> <ul style="list-style-type: none"> <li>● Drug-eluting stent (DES) is recommended in stable CAD patients undergoing stenting if there is no contraindication to prolonged dual antiplatelet therapy (DAPT).</li> <li>● Aspirin is recommended for elective stenting.</li> <li>● Clopidogrel is recommended for elective stenting.</li> <li>● Prasugrel or ticagrelor should be considered in patients with stent thrombosis on clopidogrel without treatment interruption.</li> <li>● GP IIb/IIIa antagonists should be considered for bailout situation only.</li> <li>● Platelet function testing or genetic testing may be considered in specific or high risk situations (e.g., prior history of stent thrombosis; compliance issue; suspicion of resistance; high bleeding risk) if results may change the treatment strategy.</li> <li>● Prasugrel or ticagrelor may be considered in specific high risk situations of elective stenting (e.g., left main stenting, high risk of stent thrombosis, diabetes).</li> <li>● Pretreatment with clopidogrel (when coronary anatomy is not known) is not recommended.</li> <li>● Routine platelet function testing (clopidogrel and aspirin) to adjust antiplatelet therapy before or after elective stenting is not recommended.</li> <li>● Prasugrel or ticagrelor is not recommended in low risk elective stenting.</li> <li>● After uncomplicated PCI, early cessation (<math>\leq 1</math> week) of aspirin, and continuation of dual therapy with oral anticoagulation therapy and clopidogrel should be considered if the risk of stent thrombosis is low</li> <li>● Triple therapy with aspirin, clopidogrel, and a DOAC for <math>\geq 1</math> month should be</li> </ul>

Clinical Guideline	Recommendations
	<p>considered when the risk of stent thrombosis outweighs the bleeding risk, with a total of no more than six months</p> <p><u>Follow-up of revascularized stable coronary artery disease patients</u></p> <ul style="list-style-type: none"> <li>• It is recommended that all revascularized patients receive a secondary prevention and be scheduled for follow-up visit.</li> <li>• It is recommended to instruct patients before discharge about return to work and resumption of full activities. Patients have to be advised to seek immediate medical contact if symptoms (re-) occur.</li> <li>• Single antiplatelet therapy, usually aspirin, is recommended indefinitely.</li> <li>• DAPT is indicated after bare metal stent (BMS) for at least one month.</li> <li>• DAPT is indicated for six to 12 months after 2nd generation DES.</li> <li>• DAPT may be used for more than one year in patients at high ischemic risk (e.g., stent thrombosis, recurrent acute coronary syndrome on DAPT, post MI/diffuse CAD) and low bleeding risk.</li> <li>• DAPT for one to three months may be used after DES implantation in patients at high bleeding risk or with undeferrable surgery or concomitant anticoagulant treatment.</li> </ul> <p><u>Antithrombotic therapy in patients with chronic coronary syndrome:</u></p> <ul style="list-style-type: none"> <li>• Addition of a second antithrombotic drug to aspirin for long-term secondary prevention should be considered in patients with at least a moderately increased risk of ischemic events and without high bleeding risk</li> <li>• When oral anticoagulation is initiated in patients with AF, a DOAC is recommended in preference to VKA therapy.</li> </ul>
<p>American College of Physicians/ American College of Cardiology Foundation/ American Heart Association/ American Association for Thoracic Surgery/ Preventive Cardiovascular Nurses Association/ Society of Thoracic Surgeons: <b>Management of Stable Ischemic Heart Disease (2012)</b><sup>12</sup></p>	<p><u>Medical therapy to prevent MI and death in patients with stable IHD</u></p> <ul style="list-style-type: none"> <li>• Aspirin 75 to 162 mg daily should be continued indefinitely in the absence of contraindications.</li> <li>• Treatment with clopidogrel is a reasonable option when aspirin is contraindicated.</li> <li>• Dipyridamole should not be used as antiplatelet therapy.</li> <li>• Beta-blocker therapy should be initiated and continued for three years in all patients with normal left ventricular (LV) function following MI or acute coronary syndromes.</li> <li>• Metoprolol succinate, carvedilol, or bisoprolol should be used for all patients with systolic LV dysfunction (ejection fraction <math>\leq 40\%</math>) with heart failure or prior MI, unless contraindicated.</li> <li>• ACE inhibitors should be prescribed in all patients with stable IHD who also have hypertension, diabetes, LV systolic dysfunction (ejection fraction <math>\leq 40\%</math>), and/or chronic kidney disease, unless contraindicated.</li> <li>• Angiotensin-receptor blockers (ARBs) are recommended for patients with stable IHD who have hypertension, diabetes, LV systolic dysfunction, or chronic kidney disease and have indications for, but are intolerant of, ACE inhibitors.</li> <li>• Patients should receive an annual influenza vaccine.</li> </ul> <p><u>Medical therapy for relief of symptoms in patients with stable IHD</u></p> <ul style="list-style-type: none"> <li>• Beta-blockers are recommended as initial therapy for relief of symptoms.</li> <li>• Calcium channel blockers or long-acting nitrates should be prescribed for relief of symptoms when <math>\beta</math>-blockers are contraindicated or cause unacceptable side effects.</li> <li>• Calcium channel blockers or long-acting nitrates, in combination with <math>\beta</math>-blockers, should be prescribed for relief of symptoms when initial treatment with <math>\beta</math>-blockers is unsuccessful.</li> <li>• Nitroglycerin or nitroglycerin spray should be used for immediate relief of angina.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>Ranolazine is a fourth-line agent reserved for patients who have contraindications to, do not respond to, or cannot tolerate <math>\beta</math>-blockers, calcium-channel blockers, or long-acting nitrates.</li> </ul>
<p>American College of Cardiology Foundation/American Heart Association: <b>2014 American Heart Association/ American College of Cardiology Foundation Guideline for the Management of Patients With Non-ST-Elevation Acute Coronary Syndromes (2014)</b><sup>13</sup></p>	<p><u>Early hospital care- standard medical therapies</u></p> <ul style="list-style-type: none"> <li>Supplemental oxygen should be administered to patients with non-ST-elevation acute coronary syndrome (NSTEMI-ACS) with arterial oxygen saturation &lt;90%, respiratory distress, or other high risk features of hypoxemia.</li> <li>Anti-ischemic and analgesic medications <ul style="list-style-type: none"> <li>Nitrates <ul style="list-style-type: none"> <li>Patients with NSTEMI-ACS with continuing ischemic pain should receive sublingual nitroglycerin (0.3 to 0.4 mg) every 5 minutes for up to three doses, after which an assessment should be made about the need for intravenous nitroglycerin.</li> <li>Intravenous nitroglycerin is indicated for patients with NSTEMI-ACS for the treatment of persistent ischemia, heart failure, or hypertension.</li> <li>Nitrates should not be administered to patients who recently received a phosphodiesterase inhibitor, especially within 24 hours of sildenafil or vardenafil, or within 48 hours of tadalafil.</li> </ul> </li> <li>Analgesic therapy <ul style="list-style-type: none"> <li>In the absence of contraindications, it may be reasonable to administer morphine sulphate intravenously to patients with NSTEMI-ACS if there is continued ischemic chest pain despite treatment with maximally tolerated anti-ischemic medications.</li> <li>Nonsteroidal anti-inflammatory drugs (NSAIDs) (except aspirin) should not be initiated and should be discontinued during hospitalization due to the increased risk of major adverse cardiac event associated with their use</li> </ul> </li> <li>Beta-adrenergic blockers <ul style="list-style-type: none"> <li>Oral <math>\beta</math>-blocker therapy should be initiated within the first 24 hours in patients who do not have any of the following: 1) signs of HF, 2) evidence of low-output state, 3) increased risk for cardiogenic shock, or 4) other contraindications to <math>\beta</math>-blockade (e.g., PR interval &gt;0.24 second, second- or third-degree heart block without a cardiac pacemaker, active asthma, or reactive airway disease)</li> <li>In patients with concomitant NSTEMI-ACS, stabilized heart failure, and reduced systolic function, it is recommended to continue <math>\beta</math>-blocker therapy with one of the three drugs proven to reduce mortality in patients with heart failure: sustained-release metoprolol succinate, carvedilol, or bisoprolol.</li> <li>Patients with documented contraindications to <math>\beta</math>-blockers in the first 24 hours should be re-evaluated to determine subsequent eligibility.</li> </ul> </li> <li>Calcium channel blockers (CCBs) <ul style="list-style-type: none"> <li>In patients with NSTEMI-ACS, continuing or frequently recurring ischemia, and a contraindication to <math>\beta</math>-blockers, a nondihydropyridine CCB (e.g., verapamil or diltiazem) should be given as initial therapy in the absence of clinically significant LV dysfunction, increased risk for cardiogenic shock, PR interval &gt;0.24 seconds, or second or third degree atrioventricular block without a cardiac pacemaker.</li> <li>Oral nondihydropyridine calcium antagonists are recommended in patients with NSTEMI-ACS who have recurrent ischemia in the absence of contraindications, after appropriate use of <math>\beta</math>-blockers and nitrates.</li> <li>CCBs are recommended for ischemic symptoms when <math>\beta</math>-blockers are not successful, are contraindicated, or cause unacceptable side effects.</li> <li>Long-acting CCBs and nitrates are recommended in patients with coronary artery spasm.</li> <li>Immediate-release nifedipine should not be administered to patients</li> </ul> </li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>with NSTEMI-ACS in the absence of <math>\beta</math>-blocker therapy.</p> <ul style="list-style-type: none"> <li>○ Other anti-ischemic interventions           <ul style="list-style-type: none"> <li>▪ Ranolazine is currently indicated for treatment of chronic angina; however, it may also improve outcomes in NSTEMI-ACS patients due to a reduction in recurrent ischemia.</li> </ul> </li> <li>○ Cholesterol management           <ul style="list-style-type: none"> <li>▪ High-intensity statin therapy should be initiated or continued in all patients with NSTEMI-ACS and no contraindications to its use. Treatment with statins reduces the rate of recurrent MI, coronary heart disease mortality, need for myocardial revascularization, and stroke.</li> <li>▪ It is reasonable to obtain a fasting lipid profile in patients with NSTEMI-ACS, preferably within 24 hours of presentation.</li> </ul> </li> <li>● Inhibitors of renin-angiotensin-aldosterone system           <ul style="list-style-type: none"> <li>○ ACE inhibitors should be started and continued indefinitely in all patients with LVEF &lt;0.40 and in those with hypertension, diabetes mellitus, or stable CKD, unless contraindicated.</li> <li>○ ARBs are recommended in patients with heart failure or myocardial infarction with LVEF &lt;0.40 who are ACE inhibitor intolerant.</li> <li>○ Aldosterone-blockade is recommended in patients post-MI without significant renal dysfunction (creatinine &gt;2.5 mg/dL in men or &gt;2.0 mg/dL in women) or hyperkalemia (K &gt;5.0 mEq/L) who are receiving therapeutic doses of ACE inhibitor and <math>\beta</math>-blocker and have a LVEF &lt;0.40, diabetes mellitus, or heart failure.</li> </ul> </li> <li>● Initial antiplatelet/anticoagulant therapy in patients with definite or likely NSTEMI-ACS treated with an initial invasive or ischemia-guided strategy           <ul style="list-style-type: none"> <li>○ Non-enteric coated, chewable aspirin (162 to 325 mg) should be given to all patients with NSTEMI-ACS without contraindications as soon as possible after presentation, and a maintenance dose of aspirin (81 to 162 mg/day) should be continued indefinitely.</li> <li>○ In patients who are unable to take aspirin because of hypersensitivity or major gastrointestinal intolerance, a loading dose of clopidogrel followed by a daily maintenance dose should be administered.</li> <li>○ A P2Y<sub>12</sub> receptor inhibitor (clopidogrel or ticagrelor) in addition to aspirin should be administered for up to 12 months to all patients with NSTEMI-ACS without contraindications who are treated with an early invasive or ischemia-guided strategy. Options include:               <ul style="list-style-type: none"> <li>▪ Clopidogrel: 300 or 600 mg loading dose, then 75 mg daily.</li> <li>▪ Ticagrelor: 180 mg loading dose, then 90 mg twice daily.</li> <li>▪ It is reasonable to use ticagrelor in preference to clopidogrel for P2Y<sub>12</sub> treatment in patients with NSTEMI-ACS who undergo an early invasive or ischemia-guided strategy.</li> <li>▪ In patients with NSTEMI-ACS treated with an early invasive strategy and dual antiplatelet therapy (DAPT) with intermediate/high-risk features (e.g., positive troponin), a GP IIb/IIIa inhibitor may be considered as part of initial antiplatelet therapy. Preferred options are eptifibatid or tirofiban.</li> </ul> </li> </ul> </li> </ul> <p><u>Percutaneous coronary intervention (PCI)- Antiplatelet and anticoagulant therapy</u></p> <ul style="list-style-type: none"> <li>● Antiplatelet agents           <ul style="list-style-type: none"> <li>○ Patients already taking daily aspirin before PCI should take 81 to 325 mg non-enteric coated aspirin before PCI</li> <li>○ Patients not on aspirin therapy should be given non-enteric coated aspirin 325 mg as soon as possible before PCI.</li> <li>○ After PCI, aspirin should be continued indefinitely.</li> <li>○ A loading dose of a P2Y<sub>12</sub> inhibitor should be given before the procedure in patients undergoing PCI with stenting. Options include clopidogrel 600 mg,</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>prasugrel 60 mg, or ticagrelor 180 mg.</p> <ul style="list-style-type: none"> <li>○ In patients with NSTEMI-ACS and high-risk features (e.g., elevated troponin) not adequately pretreated with clopidogrel or ticagrelor, it is useful to administer a GP IIb/IIIa inhibitor (abciximab, double-bolus eptifibatide, or high-dose bolus tirofiban) at the time of PCI.</li> <li>○ In patients receiving a stent (bare metal or drug eluting) during PCI, P2Y<sub>12</sub> inhibitor therapy should be given for at least 12 months. Options include clopidogrel 75 mg daily, prasugrel 10 mg daily, or ticagrelor 90 mg twice daily.</li> </ul> <ul style="list-style-type: none"> <li>● Anticoagulant therapy           <ul style="list-style-type: none"> <li>○ An anticoagulant should be administered to patients with NSTEMI-ACS undergoing PCI to reduce the risk of intracoronary and catheter thrombus formation.</li> <li>○ Intravenous unfractionated heparin (UFH) is useful in patients with NSTEMI-ACS undergoing PCI.</li> <li>○ Bivalirudin is useful as an anticoagulant with or without prior treatment with UFH.</li> <li>○ An additional dose of 0.3 mg/kg intravenous enoxaparin should be administered at the time of PCI to patients with NSTEMI-ACS who have received fewer than two therapeutic subcutaneous doses or received the last subcutaneous enoxaparin dose eight to 12 hours before PCI.</li> <li>○ If PCI is performed while the patient is on fondaparinux, an additional 85 IU/kg of UFH should be given intravenously immediately before PCI because of the risk of catheter thrombosis (60 IU/kg IV if a GP IIb/IIIa inhibitor used with UFH dosing based on the target-activated clotting time).</li> <li>○ Anticoagulant therapy should be discontinued after PCI unless there is a compelling reason to continue.</li> </ul> </li> <li>● Timing of CABG in relation to use of antiplatelet agents           <ul style="list-style-type: none"> <li>○ Non-enteric coated aspirin (81 to 325 mg daily) should be administered preoperatively to patients undergoing CABG.</li> <li>○ In patients referred for elective CABG, clopidogrel and ticagrelor should be discontinued for at least five days before surgery and prasugrel for at least seven days before surgery.</li> <li>○ In patients referred for urgent CABG, clopidogrel and ticagrelor should be discontinued for at least 24 hours to reduce major bleeding.</li> <li>○ In patients referred for CABG, short-acting intravenous GP IIb/IIIa inhibitors (eptifibatide or tirofiban) should be discontinued for at least 2 to 4 hours before surgery and abciximab for at least 12 hours before to limit blood loss and transfusion.</li> </ul> </li> </ul> <p><u>Late hospital care, hospital discharge, and posthospital discharge care</u></p> <ul style="list-style-type: none"> <li>● Medications at discharge           <ul style="list-style-type: none"> <li>○ Medications required in the hospital to control ischemia should be continued after hospital discharge in patients with NSTEMI-ACS who do not undergo coronary revascularization, patients with incomplete or unsuccessful revascularization, and patients with recurrent symptoms after revascularization. Titration of the doses may be required.</li> <li>○ All patients who are post-NSTEMI-ACS should be given sublingual or spray nitroglycerin with verbal and written instructions for its use.</li> <li>○ Before hospital discharge, patients with NSTEMI-ACS should be informed about symptoms of worsening myocardial ischemia and MI and should be given verbal and written instructions about how and when to seek emergency care for such symptoms.</li> <li>○ Before hospital discharge, patients who are post-NSTEMI-ACS and/or designated responsible caregivers should be provided with easily understood and culturally sensitive verbal and written instructions about medication</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>type, purpose, dose, frequency, side effects, and duration of use.</p> <ul style="list-style-type: none"> <li>○ For patients who are post–NSTE-ACS and have initial angina lasting more than one minute, nitroglycerin (one dose sublingual or spray) is recommended if angina does not subside within three to five minutes; call 9-1-1 immediately to access emergency medical services.</li> <li>○ If the pattern or severity of angina changes, suggesting worsening myocardial ischemia (e.g., pain is more frequent or severe or is precipitated by less effort or occurs at rest), patients should contact their clinician without delay to assess the need for additional treatment or testing.</li> <li>○ Before discharge, patients should be educated about modification of cardiovascular risk factors.</li> </ul> <ul style="list-style-type: none"> <li>● Late hospital and post-hospital oral antiplatelet therapy           <ul style="list-style-type: none"> <li>○ Aspirin should be continued indefinitely. The dose should be 81 mg daily in patients treated with ticagrelor and 81 to 325 mg daily in all other patients.</li> <li>○ In addition to aspirin, a P2Y<sub>12</sub> inhibitor (either clopidogrel or ticagrelor) should be continued for up to 12 months in all patients with NSTE-ACS without contraindications who are treated with an ischemia-guided strategy.</li> <li>○ In patients receiving a stent (bare-metal stent or DES) during PCI for NSTE-ACS, P2Y<sub>12</sub> inhibitor therapy should be given for at least 12 months.</li> </ul> </li> <li>● Combined oral anticoagulant therapy and antiplatelet therapy in patients with NSTE-ACS           <ul style="list-style-type: none"> <li>○ The duration of triple antithrombotic therapy with a vitamin K antagonist, aspirin, and a P2Y<sub>12</sub> receptor inhibitor in patients with NSTE-ACS should be minimized to the extent possible to limit the risk of bleeding.</li> <li>○ Proton pump inhibitors should be prescribed in patients with NSTE-ACS with a history of gastrointestinal bleeding who require triple antithrombotic therapy with a vitamin K antagonist, aspirin, and a P2Y<sub>12</sub> receptor inhibitor.</li> </ul> </li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Management of Acute Coronary Syndromes in Patients Presenting without Persistent ST-Segment Elevation (2020)</b><sup>14</sup></p>	<p><u>Pharmacological treatment of ischemia</u></p> <ul style="list-style-type: none"> <li>● Sublingual or intravenous nitrates and early initiation of β-blocker treatment is recommended in patients with ongoing ischemic symptoms and without contraindications.</li> <li>● Continuation of chronic β-blocker therapy is recommended unless the patient is in overt heart failure</li> <li>● Sublingual or intravenous nitrates are recommended to relieve angina; intravenous treatment is recommended in patients with recurrent angina, uncontrolled hypertension, or signs of heart failure.</li> <li>● In patients with suspected/confirmed vasospastic angina, calcium channel blockers, and nitrates should be considered and β-blockers avoided.</li> </ul> <p><u>Recommendations for platelet inhibition in non-ST-elevation acute coronary syndromes</u></p> <ul style="list-style-type: none"> <li>● Aspirin is recommended for all patients without contraindications at an initial oral loading dose of 150 to 300 mg (in aspirin-naïve patients) and a maintenance dose of 75 to 100 mg/day long-term regardless of treatment strategy.</li> <li>● A P2Y<sub>12</sub> inhibitor is recommended, in addition to aspirin, for 12 months unless there are contraindications such as excessive risks of bleeds.           <ul style="list-style-type: none"> <li>○ Ticagrelor (180 mg loading dose, 90 mg twice daily) is recommended, in the absence of contraindication, for all patients at moderate-to-high risk of ischemic events (e.g., elevated cardiac troponins), regardless of initial treatment strategy and including those pretreated with clopidogrel (which should be discontinued when ticagrelor is started).</li> <li>○ Prasugrel (60 mg loading dose, 10 mg daily dose) is recommended in patients who are proceeding to PCI if no contraindication. Prasugrel should be considered in preference to ticagrelor in NSTE-ACS patients who proceed to PCI.</li> <li>○ Clopidogrel (300 to 600 mg loading dose, 75 mg daily dose) is</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>recommended for patients who cannot receive ticagrelor or prasugrel or who require oral anticoagulation.</p> <ul style="list-style-type: none"> <li>• P2Y<sub>12</sub> inhibitor administration for a shorter duration of three to six months after DES implantation may be considered in patients deemed at high bleeding risk.</li> <li>• Pre-treatment with a P2Y<sub>12</sub> inhibitor may be considered in patients with NSTEMI-ACS who are not planned to undergo an early invasive strategy.</li> <li>• It is not recommended to administer routine pre-treatment with a P2Y<sub>12</sub> inhibitor in patients in whom coronary anatomy is not known.</li> <li>• It is not recommended to administer prasugrel in patients whom coronary anatomy is not known.</li> <li>• GPIIb/IIIa inhibitors during PCI should be considered for bailout situations or thrombotic complications.</li> <li>• Cangrelor may be considered in P2Y<sub>12</sub> inhibitor-naïve patients undergoing PCI.</li> <li>• It is not recommended to administer GPIIb/IIIa inhibitors in patients whom coronary anatomy is not known.</li> <li>• P2Y<sub>12</sub> inhibitor administration in addition to aspirin beyond one year may be considered after careful assessment of the ischemic and bleeding risks of the patient.</li> </ul> <p><u>Recommendations for anticoagulation in non-ST-elevation acute coronary syndromes</u></p> <ul style="list-style-type: none"> <li>• Parenteral anticoagulation is recommended at the time of diagnosis according to both ischemic and bleeding risks.</li> <li>• Fondaparinux is recommended as having the most favorable efficacy-safety profile regardless of the management strategy.</li> <li>• Bivalirudin is recommended as an alternative to UFH plus GPIIb/IIIa inhibitors during PCI.</li> <li>• UFH is recommended in patients undergoing PCI who did not receive any anticoagulant.</li> <li>• In patients on fondaparinux undergoing PCI, a single intravenous bolus of UFH is recommended during the procedure.</li> <li>• Enoxaparin or UFH are recommended when fondaparinux is not available.</li> <li>• Enoxaparin should be considered as an anticoagulant for PCI in patients pretreated for PCI with subcutaneous enoxaparin.</li> <li>• Additional activated clotting time-guided intravenous boluses of UFH during PCI may be considered following initial UFH treatment.</li> <li>• Discontinuation of anticoagulation should be considered after PCI, unless otherwise indicated.</li> <li>• Crossover between UFH and LMWH is not recommended.</li> <li>• In NSTEMI patients with no prior stroke/TIA and at high ischemic risk as well as low bleeding risk receiving aspirin and clopidogrel, low-dose rivaroxaban (2.5 mg twice daily for approximately one year) may be considered after discontinuation of parenteral anticoagulation.</li> </ul> <p><u>Recommendations for combining antiplatelet agents and anticoagulants in non-ST-elevation acute coronary syndrome patients requiring chronic oral anticoagulation</u></p> <ul style="list-style-type: none"> <li>• In patients with a firm indication for oral anticoagulation (e.g., atrial fibrillation with a CHADS<sub>2</sub>-VASc score ≥2, recent VTE, mechanical valve prosthesis), oral anticoagulation is recommended in addition to antiplatelet therapy.</li> <li>• An early invasive coronary angiography (within 24 hours) should be considered in moderate- to high-risk patients, irrespective of oral anticoagulant exposure, to expedite treatment allocation (medical vs PCI vs CABG) and to determine optimal antithrombotic regimen.</li> <li>• Initial dual antiplatelet therapy with aspirin plus a P2Y<sub>12</sub> inhibitor in addition to oral anticoagulation before coronary angiography is not recommended.</li> <li>• During PCI, additional parenteral anticoagulation is recommended, irrespective</li> </ul>

Clinical Guideline	Recommendations
	<p>of the timing of the last dose of all non-vitamin K antagonist oral anticoagulants (NOACs) and if INR is &lt;2.5 in VKA-treated patients.</p> <ul style="list-style-type: none"> <li>• Uninterrupted therapeutic anticoagulation with VKA or NOACs should be considered during the periprocedural phase.</li> <li>• Periprocedural DAPT administration consisting of aspirin and clopidogrel up to one week is recommended</li> <li>• Discontinuation of antiplatelet treatment in patients treated with an oral anticoagulant is recommended after 12 months</li> <li>• Following coronary stenting, dual (oral) antiplatelet therapy (DAPT) including new P2Y<sub>12</sub> inhibitors should be considered as an alternative to triple therapy for patients with non-ST-elevation acute coronary syndromes and atrial fibrillation with a CHADS<sub>2</sub>-VASc score of 1 (in males) or 2 (in females).</li> <li>• If at low bleeding risk (HAS-BLED ≤2), triple therapy with oral anticoagulant, aspirin, and clopidogrel should be considered for six months, followed by oral anticoagulant and aspirin or clopidogrel continued up to 12 months.</li> <li>• If at high bleeding risk (HAS-BLED ≥3), triple therapy with oral anticoagulant, aspirin, and clopidogrel should be considered for one month, followed by oral anticoagulant and aspirin or clopidogrel continued up to 12 months irrespective of the stent type.</li> <li>• Dual therapy with oral anticoagulant and clopidogrel may be considered as an alternative to triple antithrombotic therapy in selected patients (HAS-BLED ≥3 and low risk of stent thrombosis).</li> <li>• The use of ticagrelor or prasugrel as part of triple therapy is not recommended.</li> <li>• In medically managed patients, one antiplatelet agent in addition to oral anticoagulant should be considered for up to one year.</li> </ul> <p><u>Recommendations for post-interventional and maintenance treatment</u></p> <ul style="list-style-type: none"> <li>• In patients with NSTEMI-ACS with coronary stent implantation, DAPT with a P2Y<sub>12</sub> inhibitor on top of aspirin is recommended for 12 months unless there are contraindications such as excessive risk of bleeding.</li> <li>• Adding a second anti-thrombotic agent to aspirin for extended long-term secondary prevention should be considered in patients with a moderate to high risk of ischemic events and without increased risk of major bleeding.</li> <li>• After stent implantation with high risk of bleeding, discontinuation of P2Y<sub>12</sub> inhibitor therapy after three months should be considered</li> <li>• After stent implantation in patients undergoing DAPT, stopping aspirin after three to six months should be considered, depending on balance between ischemic and bleeding risk.</li> <li>• De-escalation of P2Y<sub>12</sub> inhibitor treatment may be considered as an alternative DAPT strategy, especially for ACS patients deemed unsuitable for potent platelet inhibition.</li> </ul>
<p>American College of Cardiology/American Heart Association:  <b>Guideline for the Management of ST-Elevation Myocardial Infarction (2013)</b><sup>15</sup></p>	<p><u>Routine medical therapies: β-blockers</u></p> <ul style="list-style-type: none"> <li>• Oral β-blockers should be initiated within the first 24 hours in patients with an ST-segment elevation myocardial infarction (STEMI) who do not have any of the following: 1) signs of heart failure, 2) evidence of a low-output state, 3) increased risk of cardiogenic shock, 4) other contraindications to use of oral β-blockers (e.g., PR interval &gt;24 seconds, second or third degree heart block, active asthma, reactive airway disease).</li> <li>• β-blockers should be continued during and after hospitalization for all patients with STEMI and with no contraindications to their use.</li> <li>• Patients with initial contraindications to the use of β-blockers in the first 24 hours after STEMI should be re-evaluated to determine their subsequent eligibility.</li> <li>• It is reasonable to administer intravenous β-blockers at the time of presentation to patients with STEMI and no contraindications to their use who are hypertensive or have ongoing ischemia.</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Routine medical therapies: renin-angiotensin-aldosterone system inhibitors</u></p> <ul style="list-style-type: none"> <li>• An ACE inhibitor should be administered within the first 24 hours to all patients with ST-segment elevation myocardial infarction with anterior location, heart failure, or ejection fraction <math>\leq 40\%</math>, unless contraindicated.</li> <li>• An ARB should be given to patients who have indications for but are intolerant of ACE inhibitors.</li> <li>• ACE inhibitors are reasonable for all patients with no contraindications to their use.</li> <li>• An aldosterone antagonist should be given to patients with STEMI and no contraindications who are already receiving an ACE inhibitor and <math>\beta</math>-blocker and who have an EF <math>\leq 40\%</math> and either symptomatic heart failure or diabetes.</li> </ul> <p><u>Routine medical therapies: Lipid management</u></p> <ul style="list-style-type: none"> <li>• High-intensity statin therapy should be initiated or continued in all patients with STEMI and no contraindications to its use.</li> <li>• It is reasonable to obtain a fasting lipid profile in patients with STEMI, preferably within 24 hours of presentation.</li> </ul>
<p>European Society of Cardiology: <b>Management of Acute Myocardial Infarction in Patients Presenting with ST-segment Elevation (2017)</b><sup>16</sup></p>	<p><u>Routine therapies in the acute, subacute and long term phase of ST-elevation myocardial infarction (STEMI)</u></p> <ul style="list-style-type: none"> <li>• Antiplatelet therapy with low dose aspirin (75 to 100 mg) is indicated indefinitely after STEMI.</li> <li>• Dual antiplatelet therapy with a combination of aspirin and prasugrel or aspirin and ticagrelor is recommended for 12 months after percutaneous coronary intervention (PCI), unless there are contraindications such as excessive risk of bleeding.</li> <li>• A proton pump inhibitor (PPI) in combination with dual antiplatelet therapy is recommended in patients at high risk of gastrointestinal bleeding.</li> <li>• In patients with an indication for oral anticoagulation, oral anticoagulants are indicated in addition to antiplatelet therapy.</li> <li>• In patients who are at high risk of severe bleeding complications, discontinuation of P2Y<sub>12</sub> inhibitor therapy after six months should be considered.</li> <li>• In STEMI patients with stent implantation and an indication for oral anticoagulation, triple therapy (oral anticoagulant, aspirin, and clopidogrel) should be considered for one to six months (according a balance between the estimated risk of recurrent coronary events and bleeding).</li> <li>• In patients with left ventricular thrombus, anticoagulation should be instituted for a minimum of six months, guided by repeated imaging.</li> <li>• In selected patients who receive aspirin and clopidogrel, low-dose rivaroxaban (2.5 mg twice daily) may be considered if the patient is at low bleeding risk.</li> <li>• Dual antiplatelet therapy should be used up to one year in patients with STEMI who did not receive a stent unless there are contraindications such as excessive risk of bleeding.</li> <li>• In high ischemic-risk patients (age <math>\geq 50</math> years, and at least one of the following risk factors: age <math>\geq 65</math> years, diabetes mellitus on medication, prior spontaneous MAI, multivessel CAD, or chronic renal dysfunction with eGFR <math>&lt; 60</math> mL/min) who have tolerated dual antiplatelet therapy without a bleeding complication, treatment with dual antiplatelet therapy in the form of ticagrelor 60 mg twice a day on top of aspirin for longer than 12 months may be considered for up to three years.</li> <li>• The use of ticagrelor or prasugrel is not recommended as part of triple antithrombotic therapy with aspirin and oral anticoagulation.</li> <li>• Oral treatment with <math>\beta</math>-blockers should be considered during hospital stay and continued thereafter in all patients without contraindications.</li> <li>• Oral treatment with <math>\beta</math>-blockers is indicated in patients with heart failure or left</li> </ul>

Clinical Guideline	Recommendations
	<p>ventricular dysfunction, LVEF <math>\leq</math>40% unless contraindicated.</p> <ul style="list-style-type: none"> <li>• Intravenous <math>\beta</math>-blockers must be avoided in patients with hypotension or acute heart failure or AV block or severe bradycardia.</li> <li>• Intravenous <math>\beta</math>-blockers should be considered at the time of presentation in patients undergoing primary PCI without contraindications, with high blood pressure, tachycardia, and no signs of heart failure.</li> <li>• A fasting lipid profile must be obtained in all STEMI patients, as soon as possible after presentation.</li> <li>• It is recommended to initiate or continue high dose statins early after admission in all STEMI patients without contraindication or history of intolerance, regardless of initial cholesterol values and maintain it long-term.</li> <li>• An LDL-C goal of <math>&lt;1.8</math> mmol/L (70 mg/dL) or a reduction of at least 50% if the baseline LDL-C is between 1.8 to 3.5 mmol/L (70 to 135 mg/dL) is recommended.</li> <li>• In patients with LDL-C <math>&gt;1.8</math> mmol/L (<math>&gt;70</math> mg/dL) despite a maximally tolerated statin dose who remain at high risk, further therapy to reduce LDL-C should be considered.</li> <li>• ACE inhibitors are indicated starting within the first 24 hours of STEMI in patients with evidence of heart failure, LV systolic dysfunction, diabetes or an anterior infarct.</li> <li>• An ARB, preferably valsartan, is an alternative to ACE inhibitors in patients with heart failure or LV systolic dysfunction, particularly those who are intolerant to ACE inhibitors.</li> <li>• ACE inhibitors should be considered in all patients in the absence of contraindications.</li> <li>• Aldosterone antagonists, e.g. eplerenone, are indicated in patients with an ejection fraction <math>\leq</math>40% and heart failure or diabetes, provided no renal failure or hyperkalemia.</li> </ul>
<p>American College of Cardiology/ American Heart Association: <b>Guideline on the Primary Prevention of Cardiovascular Disease (2019)</b><sup>17</sup></p>	<p><u>Top 10 messages for the primary prevention of cardiovascular disease</u></p> <ul style="list-style-type: none"> <li>• The most important way to prevent atherosclerotic vascular disease, heart failure, and atrial fibrillation is to promote a healthy lifestyle throughout life.</li> <li>• A team-based care approach is an effective strategy for the prevention of cardiovascular disease. Clinicians should evaluate the social determinants of health that affect individuals to inform treatment decisions.</li> <li>• Adults who are 40 to 75 years of age and are being evaluated for cardiovascular disease prevention should undergo 10-year atherosclerotic cardiovascular disease (ASCVD) risk estimation and have a clinician–patient risk discussion before starting on pharmacological therapy, such as antihypertensive therapy, a statin, or aspirin. In addition, assessing for other risk-enhancing factors can help guide decisions about preventive interventions in select individuals, as can coronary artery calcium scanning.</li> <li>• All adults should consume a healthy diet that emphasizes the intake of vegetables, fruits, nuts, whole grains, lean vegetable or animal protein, and fish and minimizes the intake of trans fats, processed meats, refined carbohydrates, and sweetened beverages. For adults with overweight and obesity, counseling and caloric restriction are recommended for achieving and maintaining weight loss.</li> <li>• Adults should engage in at least 150 minutes per week of accumulated moderate-intensity physical activity or 75 minutes per week of vigorous-intensity physical activity.</li> <li>• For adults with type 2 diabetes mellitus, lifestyle changes, such as improving dietary habits and achieving exercise recommendations, are crucial. If medication is indicated, metformin is first-line therapy, followed by consideration of a sodium-glucose cotransporter 2 inhibitor or a glucagon-like peptide-1 receptor agonist.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• All adults should be assessed at every healthcare visit for tobacco use, and those who use tobacco should be assisted and strongly advised to quit.</li> <li>• Aspirin should be used infrequently in the routine primary prevention of ASCVD because of lack of net benefit.</li> <li>• Statin therapy is first-line treatment for primary prevention of ASCVD in patients with elevated low-density lipoprotein cholesterol levels (<math>\geq 190</math> mg/dL), those with diabetes mellitus, who are 40 to 75 years of age, and those determined to be at sufficient ASCVD risk after a clinician–patient risk discussion.</li> <li>• Nonpharmacological interventions are recommended for all adults with elevated blood pressure or hypertension. For those requiring pharmacological therapy, the target blood pressure should generally be <math>&lt;130/80</math> mm Hg.</li> </ul> <p><u>Adults with Type 2 Diabetes Mellitus</u></p> <ul style="list-style-type: none"> <li>• For all adults with T2DM, a tailored nutrition plan focusing on a heart-healthy dietary pattern is recommended to improve glycemic control, achieve weight loss if needed, and improve other ASCVD risk factors.</li> <li>• Adults with T2DM should perform at least 150 minutes per week of moderate-intensity physical activity or 75 minutes of vigorous-intensity physical activity to improve glycemic control, achieve weight loss if needed, and improve other ASCVD risk factors.</li> <li>• For adults with T2DM, it is reasonable to initiate metformin as first-line therapy along with lifestyle therapies at the time of diagnosis to improve glycemic control and reduce ASCVD risk.</li> <li>• For adults with T2DM and additional ASCVD risk factors who require glucose-lowering therapy despite initial lifestyle modifications and metformin, it may be reasonable to initiate a sodium-glucose cotransporter 2 (SGLT-2) inhibitor or a glucagon-like peptide-1 receptor (GLP-1R) agonist to improve glycemic control and reduce CVD risk.</li> </ul> <p><u>Adults with high blood cholesterol</u></p> <ul style="list-style-type: none"> <li>• In adults at intermediate risk (<math>\geq 7.5\%</math> to <math>&lt;20\%</math> 10-year ASCVD risk), statin therapy reduces risk of ASCVD, and in the context of a risk discussion, if a decision is made for statin therapy, a moderate-intensity statin should be recommended.</li> <li>• In intermediate risk (<math>\geq 7.5\%</math> to <math>&lt;20\%</math> 10-year ASCVD risk) patients, LDL-C levels should be reduced by 30% or more, and for optimal ASCVD risk reduction, especially in patients at high risk (<math>\geq 20\%</math> 10-year ASCVD risk), levels should be reduced by 50% or more.</li> <li>• In adults 40 to 75 years of age with diabetes, regardless of estimated 10-year ASCVD risk, moderate-intensity statin therapy is indicated.</li> <li>• In patients 20 to 75 years of age with an LDL-C level of 190 mg/dL (<math>\geq 4.9</math> mmol/L) or higher, maximally tolerated statin therapy is recommended.</li> <li>• In adults with diabetes mellitus who have multiple ASCVD risk factors, it is reasonable to prescribe high-intensity statin therapy with the aim to reduce LDL-C levels by 50% or more.</li> <li>• In intermediate-risk (<math>\geq 7.5\%</math> to <math>&lt;20\%</math> 10-year ASCVD risk) adults, risk-enhancing factors favor initiation or intensification of statin therapy.</li> <li>• In intermediate-risk (<math>\geq 7.5\%</math> to <math>&lt;20\%</math> 10-year ASCVD risk) adults or selected borderline-risk (5% to <math>&lt;7.5\%</math> 10-year ASCVD risk) adults in whom a coronary artery calcium score is measured for the purpose of making a treatment decision, AND <ul style="list-style-type: none"> <li>○ If the coronary artery calcium score is zero, it is reasonable to withhold statin therapy and reassess in five to 10 years, as long as higher-risk conditions are absent (e.g., diabetes, family history of premature CHD, cigarette smoking);</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>○ If coronary artery calcium score is one to 99, it is reasonable to initiate statin therapy for patients <math>\geq 55</math> years of age;</li> <li>○ If coronary artery calcium score is 100 or higher or in the 75th percentile or higher, it is reasonable to initiate statin therapy.</li> </ul> <ul style="list-style-type: none"> <li>● In patients at borderline risk (5% to <math>&lt;7.5\%</math> 10-year ASCVD risk), in risk discussion, the presence of risk-enhancing factors may justify initiation of moderate-intensity statin therapy.</li> </ul> <p><u>Adults with high blood pressure or hypertension</u></p> <ul style="list-style-type: none"> <li>● In adults with elevated blood pressure (BP) or hypertension, including those requiring antihypertensive medications nonpharmacological interventions are recommended to reduce BP. These include:           <ul style="list-style-type: none"> <li>○ weight loss;</li> <li>○ a heart-healthy dietary pattern;</li> <li>○ sodium reduction;</li> <li>○ dietary potassium supplementation;</li> <li>○ increased physical activity with a structured exercise program; and</li> <li>○ limited alcohol.</li> </ul> </li> <li>● In adults with an estimated 10-year ASCVD risk (ACC/AHA pooled cohort equations to estimate 10-year risk of ASCVD) of 10% or higher and an average systolic BP (SBP) of 130 mm Hg or higher or an average diastolic BP (DBP) of 80 mm Hg or higher, use of BP-lowering medications is recommended for primary prevention of CVD.</li> <li>● In adults with confirmed hypertension and a 10-year ASCVD event risk of 10% or higher, a BP target of less than 130/80 mm Hg is recommended.</li> <li>● In adults with hypertension and chronic kidney disease, treatment to a BP goal of less than 130/80 mm Hg is recommended.</li> <li>● In adults with T2DM and hypertension, antihypertensive drug treatment should be initiated at a BP of 130/80 mm Hg or higher, with a treatment goal of less than 130/80 mm Hg.</li> <li>● In adults with an estimated 10-year ASCVD risk <math>&lt;10\%</math> and an SBP of 140 mm Hg or higher or a DBP of 90 mm Hg or higher, initiation and use of BP-lowering medication are recommended.</li> <li>● In adults with confirmed hypertension without additional markers of increased ASCVD risk, a BP target of less than 130/80 mm Hg may be reasonable.</li> </ul> <p><u>Recommendations for treatment of tobacco use</u></p> <ul style="list-style-type: none"> <li>● All adults should be assessed at every healthcare visit for tobacco use and their tobacco use status recorded as a vital sign to facilitate tobacco cessation.</li> <li>● To achieve tobacco abstinence, all adults who use tobacco should be firmly advised to quit.</li> <li>● In adults who use tobacco, a combination of behavioral interventions plus pharmacotherapy is recommended to maximize quit rates.</li> <li>● In adults who use tobacco, tobacco abstinence is recommended to reduce ASCVD risk.</li> <li>● To facilitate tobacco cessation, it is reasonable to dedicate trained staff to tobacco treatment in every healthcare system.</li> <li>● All adults and adolescents should avoid secondhand smoke exposure to reduce ASCVD risk.</li> </ul> <p><u>Recommendations for aspirin use</u></p> <ul style="list-style-type: none"> <li>● Low-dose aspirin (75 to 100 mg orally daily) might be considered for the primary prevention of ASCVD among select adults 40 to 70 years of age who are at higher ASCVD risk but not at increased bleeding risk.</li> <li>● Low-dose aspirin (75 to 100 mg orally daily) should not be administered on a</li> </ul>

Clinical Guideline	Recommendations
	<p>routine basis for the primary prevention of ASCVD among adults &gt;70 years of age.</p> <ul style="list-style-type: none"> <li>• Low-dose aspirin (75 to 100 mg orally daily) should not be administered for the primary prevention of ASCVD among adults of any age who are at increased risk of bleeding.</li> </ul>
<p>American Heart Association/American College of Cardiology/Heart Failure Society of America: <b>2022 AHA/ACC/HFSA Guideline for the Management of Heart Failure (2022)</b><sup>18</sup></p>	<p><b>Treatment of Stage A heart failure (HF)</b></p> <ul style="list-style-type: none"> <li>• Hypertension should be controlled in accordance with guideline-directed medication therapy for hypertension to prevent symptomatic HF. (LoE: A)</li> <li>• In patients with type 2 diabetes and either established CVD or at high cardiovascular risk, SGLT-2 inhibitors should be used to prevent hospitalizations for HF. (LoE: A)</li> <li>• In the general population, healthy lifestyle habits such as regular physical activity, maintaining normal weight, healthy dietary patterns, and avoiding smoking are helpful to reduce future risk of HF. (LoE: B)</li> <li>• Patients at risk of developing HF, natriuretic peptide biomarker-based screening followed by team-based care, including a cardiovascular specialist optimizing therapy, can be useful to prevent the development of LV dysfunction (systolic or diastolic) or new-onset HF. (LoE: B)</li> </ul> <p><b>Treatment of Stage B heart failure</b></p> <ul style="list-style-type: none"> <li>• In patients with LVEF≤40%, ACE inhibitors should be used to prevent HF and reduce mortality. (LoE: A)</li> <li>• In patients with a recent or remote history of MI or ACS, statins should be used to prevent symptomatic HF and adverse cardiovascular events. (LoE: A)</li> <li>• In patients with a recent MI and LVEF≤40% who are intolerant to ACE inhibitors, ARB should be used to prevent symptomatic HF and reduce mortality. (LoE: B)</li> <li>• In patients with a recent or remote history of MI or ACS and LVEF≤40%, evidence-based beta blockers should be used to reduce mortality. (LoE: B)</li> <li>• In patients who are at least 40 days post-MI with LVEF≤30% and NYHA class I symptoms while receiving guideline-directed medication therapy and have reasonable expectation of meaningful survival for greater than one year, an implantable cardioverter-defibrillator is recommended for primary prevention of sudden cardiac death to reduce total mortality. (LoE: B)</li> <li>• In patients with LVEF≤40%, beta blockers should be used to prevent symptomatic HF. (LoE: C)</li> <li>• In patients with LVEF≤50%, thiazolidinediones should not be used because they increase the risk of HF, including hospitalizations. (LoE: B)</li> <li>• In patients with LVEF≤50%, nondihydropyridine calcium channel blockers with negative inotropic effects may be harmful. (LoE: C)</li> </ul> <p><b>Treatment for Stage C Heart Failure with Reduced Ejection Fraction (HFrEF)</b></p> <ul style="list-style-type: none"> <li>• For patients with stage C HF, avoiding excessive sodium intake is reasonable to reduce congestive symptoms. (LoE: C)</li> <li>• In patients with HF who have fluid retention, diuretics are recommended to relieve congestion, improve symptoms, and prevent worsening HF. (LoE: B)</li> <li>• For patients with HF and congestive symptoms, addition of a thiazide (e.g., metolazone) to treatment with a loop diuretic should be reserved for patients who do not respond to moderate or high dose loop diuretics to minimize electrolyte abnormalities. (LoE: B)</li> <li>• In patients with HFrEF and NYHA class II to III symptoms, the use of an ARNI is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, the use of an ACE inhibitor is beneficial to reduce morbidity and mortality when the use of an</li> </ul>

Clinical Guideline	Recommendations
	<p>ARNI is not feasible. (LoE: A)</p> <ul style="list-style-type: none"> <li>• In patients with previous or current symptoms of chronic HFrEF, who are intolerant to an ACE inhibitor because of cough or angioedema, and when the use of an ARNI is not feasible, the use of an ARB is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with chronic symptomatic HFrEF NYHA class II or III who tolerate an ACE inhibitor or ARB, replacement by an ARNI is recommended to further reduce morbidity and mortality. (LoE: B)</li> <li>• ARNIs should not be administered concomitantly with ACE inhibitors or within 36 hours of the last dose of an ACE inhibitor. (LoE: B)</li> <li>• ARNI or ACE inhibitors should not be administered in patients with a history of angioedema. (LoE: C)</li> <li>• In patients with HFrEF, with current or previous symptoms, use of one of the three <math>\beta</math>-blockers proven to reduce mortality (e.g., bisoprolol, carvedilol, sustained-release metoprolol succinate) is recommended to reduce mortality and hospitalizations. (LoE: A)</li> <li>• In patients with HFrEF and NYHA class II to IV symptoms, a mineralocorticoid receptor antagonist (spironolactone or eplerenone) is recommended to reduce morbidity and mortality, if eGFR is <math>&gt;30</math> mL/min/1.73 m<sup>2</sup> and serum potassium is <math>&lt;5.0</math> mEq/L. Careful monitoring of potassium, renal function, and diuretic dosing should be performed at initiation and closely followed thereafter to minimize risk of hyperkalemia and renal insufficiency. (LoE: A)</li> <li>• In patients taking a mineralocorticoid receptor antagonist whose serum potassium cannot be maintained at <math>&lt;5.5</math> mEq/L, mineralocorticoid receptor antagonist should be discontinued to avoid life threatening hyperkalemia. (LoE: B)</li> <li>• In patients with symptomatic chronic HFrEF, SGLT-2 an inhibitor is recommended to reduce hospitalization for HF and cardiovascular mortality, irrespective of the presence of type 2 diabetes. (LoE: A)</li> <li>• The combination of hydralazine and isosorbide dinitrate is recommended to improve symptoms and reduce morbidity and mortality for patients self-identified as African Americans with NYHA class III to IV HFrEF receiving optimal therapy. (LoE: A)</li> <li>• In patients with current or previous symptomatic HFrEF who cannot be given first-line agents, such as an ARNI, ACE inhibitor or ARB because of drug intolerance or renal insufficiency, a combination of hydralazine and isosorbide dinitrate might be considered to reduce morbidity and mortality. (LoE: C)</li> <li>• In patients with HF class II to IV symptoms, omega-3 polyunsaturated fatty acid supplementation may be reasonable to use as adjunctive therapy to reduce mortality and cardiovascular hospitalizations. (LoE: B)</li> <li>• In patients with chronic HFrEF without specific indication (e.g., venous thromboembolism, atrial fibrillation, a previous thromboembolic event, or a cardioembolic source, anticoagulation is not recommended. (LoE: B)</li> <li>• Dihydropyridine and non-dihydropyridine calcium channel blockers are not recommended for patients with HFrEF. (LoE: A)</li> <li>• In patients with HFrEF, vitamins, nutritional supplements, and hormonal therapy are not recommended other than to correct specific deficiencies. (LoE: B)</li> <li>• In patients with HFrEF, class IC antiarrhythmic medication and dronedarone may increase risk of mortality. (LoE: A)</li> <li>• In patients with HFrEF, thiazolidinediones increase the risk of worsening HF symptoms and hospitalizations. (LoE: A)</li> <li>• In patients with type 2 diabetes and high cardiovascular risk, the DPP-4 inhibitors, saxagliptin and alogliptin, increase the risk of HF hospitalization and should be avoided in patients with HF. (LoE: B)</li> <li>• In patients with HFrEF, nonsteroidal anti-inflammatory drugs worsen HF symptoms and should be avoided or withdrawn whenever possible. (LoE: B)</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• For patients with symptomatic (NYHA class II to III) stable chronic HFrEF (LVEF <math>\leq</math>35%) who are receiving guideline-directed medical therapy, including a maximally tolerated dose of a beta blocker, and who are in sinus rhythm with a heart rate of <math>\geq</math>70 beats per minute at rest, ivabradine can be beneficial to reduce HF hospitalizations and cardiovascular death. (LoE: B)</li> <li>• In patients with symptomatic HFrEF despite guideline-directed medical therapy or who are unable to tolerate guideline-directed medical therapy, digoxin might be considered to decrease hospitalizations for HF. (LoE: B)</li> <li>• In select high-risk patients with HFrEF and recent worsening of HF already on guideline-directed medical therapy, an oral soluble guanylate cyclase stimulator (vericiguat) may be considered to reduce HF hospitalization and cardiovascular death. (LoE: B)</li> </ul> <p><u>Pharmacological treatment for Stage C HF with mildly reduced EF and improved EF</u></p> <ul style="list-style-type: none"> <li>• In patients with HF with mildly reduced EF, SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• Among patients with current or previous symptomatic HF with mildly reduced EF (LVEF, 41 to 49%), use of evidence-based beta blockers for HFrEF, ARNI, ACE inhibitor or ARB, and mineralocorticoid receptor antagonists may be considered to reduce the risk of HF hospitalization and cardiovascular mortality, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• In patients with HF with improved EF after treatment, guideline-directed medical therapy should be continued to prevent relapse of HF and LV dysfunction, even in patients who may become asymptomatic. (LoE: B)</li> </ul> <p><u>Pharmacological treatment for Stage C HF with preserved EF (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• Patients with hypertension and HFpEF should have medication titrated to attain blood pressure targets in accordance with published clinical practice guidelines to prevent morbidity. (LoE: C)</li> <li>• SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• In patients with HFpEF, the use of a mineralocorticoid receptor antagonist, ARB, or ARNI may be considered to decrease hospitalizations, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• Routine use of nitrates or phosphodiesterase-5 inhibitors to increase activity or quality of life in patients with HFpEF is ineffective. (LoE: B)</li> </ul> <p><u>Treatment of Stage D (advanced/refractory) HF</u></p> <ul style="list-style-type: none"> <li>• For patients with advanced HF and hyponatremia, the benefit of fluid restriction to reduce congestive symptoms is uncertain. (LoE: C)</li> <li>• Continuous intravenous inotropic support is reasonable as “bridge therapy” in patients with HF (Stage D) refractory to guideline-directed medical therapy and device therapy who are eligible for and awaiting mechanical circulatory support or cardiac transplantation. (LoE: B)</li> <li>• In select patients with HF Stage D, despite optimal guideline-directed medical therapy and device therapy who are ineligible for either mechanical circulatory support or cardiac transplantation, continuous intravenous inotropic support may be considered as palliative therapy for symptom control and improvement in functional status. (LoE: B)</li> <li>• Long-term use of either continuous or intermittent, intravenous inotropic agents, for reasons other than palliative care or as a bridge to advanced therapies, is potentially harmful. (LoE: B)</li> </ul>
European Society of Cardiology:	Pharmacological treatments indicated in patients with (NYHA Class II-IV) heart failure with reduced ejection fraction

Clinical Guideline	Recommendations
<p><b>Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure (2021)</b><sup>19</sup></p>	<ul style="list-style-type: none"> <li>• An ACE inhibitor is recommended, in addition to a <math>\beta</math>-blocker, for symptomatic patients with HFrEF to reduce the risk of HF hospitalization and death.</li> <li>• A mineralocorticoid receptor antagonist (MRA) is recommended for patients with HFrEF, who remain symptomatic despite treatment with an ACE inhibitor and a <math>\beta</math>-blocker, to reduce the risk of HF hospitalization and death.</li> <li>• Dapagliflozin or empagliflozin are recommended for patients with HFrEF to reduce the risk of HF hospitalization and death. Dapagliflozin or empagliflozin are recommended, in addition to optimal medical therapy with an ACE-I/ARNI, a <math>\beta</math>-blocker and an MRA, for patients with HFrEF regardless of diabetes status.</li> <li>• Sacubitril-valsartan is recommended as a replacement for an ACE inhibitor to further reduce the risk of HF hospitalization and death in ambulatory patients with HFrEF who remain symptomatic despite optimal treatment with an ACE inhibitor, a <math>\beta</math>-blocker, and a mineralocorticoid receptor antagonist.</li> <li>• Diuretics are recommended in order to improve symptoms and exercise capacity in patients with signs and/or symptoms of congestion.</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization or cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm despite treatment with an evidence-based dose of <math>\beta</math>-blocker (or maximum tolerated dose below that), ACE inhibitor (or ARB), and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm who are unable to tolerate or have contraindications for a <math>\beta</math>-blocker. Patients should also receive an ACE inhibitor (or ARB) and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• An ARB is recommended to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients unable to tolerate an ACE inhibitor (patients should also receive a <math>\beta</math>-blocker and mineralocorticoid receptor antagonist).</li> <li>• An ARB may be considered to reduce the risk of HF hospitalization and death in patients who are symptomatic despite treatment with a <math>\beta</math>-blocker who are unable to tolerate a mineralocorticoid receptor antagonist.</li> <li>• Vericiguat may be considered in patients in NYHA class II-IV who have had worsening HF despite treatment with an ACE-I (or ARNI), a <math>\beta</math>-blocker and an MRA to reduce the risk of CV mortality or HF hospitalization.</li> <li>• Hydralazine and isosorbide dinitrate should be considered in self-identified black patients with LVEF <math>\leq 35\%</math> or with an LVEF <math>&lt; 45\%</math> combined with a dilated LV in NYHA Class III-IV despite treatment with an ACE-I a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist to reduce the risk of HF hospitalization and death.</li> <li>• Hydralazine and isosorbide dinitrate may be considered in symptomatic patients with HFrEF who can tolerate neither an ACE inhibitor nor an ARB (or they are contraindicated) to reduce the risk of death.</li> <li>• Digoxin is a treatment with less-certain benefits and may be considered in symptomatic patients in sinus rhythm despite treatment with an ACE inhibitor (or ARB), a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist, to reduce the risk of hospitalization (both all-cause and HF-hospitalizations).</li> </ul> <p><u>Recommendations for treatment of patients with (NYHA class II-IV) heart failure with mildly reduced ejection fraction (HFmrEF)</u></p> <ul style="list-style-type: none"> <li>• Diuretics are recommended in patients with congestion and HFmrEF in order to alleviate symptoms and signs.</li> <li>• An ACE inhibitor may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An ARB may be considered for patients with HFmrEF to reduce the risk of HF</li> </ul>

Clinical Guideline	Recommendations
	<p>hospitalization and death.</p> <ul style="list-style-type: none"> <li>• A <math>\beta</math>-blocker may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An MRA may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• Sacubitril/valsartan may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> </ul> <p><u>Recommendations for treatment of patients with heart failure with preserved ejection fraction (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• It is recommended to screen patients with HFpEF for both cardiovascular and noncardiovascular comorbidities, which, if present, should be treated provided safe and effective interventions exist to improve symptoms, well-being and/or prognosis.</li> <li>• Diuretics are recommended in congested patients with HFpEF in order to alleviate symptoms and signs.</li> </ul> <p><u>Recommendations for the primary prevention of heart failure in patients with risk factors for its development</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension is recommended to prevent or delay the onset of HF and prolong life.</li> <li>• Treatment with statins is recommended in patients at high risk of CV disease or with CV disease in order to prevent or delay the onset of HF, and to prevent HF hospitalizations.</li> <li>• SGLT2 inhibitors (canagliflozin, dapagliflozin, empagliflozin, ertugliflozin, sotagliflozin) are recommended in patients with diabetes at high risk of CV disease or with CV disease in order to prevent HF hospitalizations.</li> <li>• Counselling against sedentary habit, obesity, cigarette smoking, and alcohol abuse is recommended to prevent or delay the onset of HF.</li> </ul> <p><u>Recommendations for the initial management of patients with acute heart failure – pharmacotherapy</u></p> <ul style="list-style-type: none"> <li>• Intravenous loop diuretics are recommended for all patients with acute HF admitted with signs/symptoms of fluid overload to improve symptoms. It is recommended to regularly monitor symptoms, urine output, renal function and electrolytes during use of intravenous diuretics.</li> <li>• Combination of a loop diuretic with thiazide type diuretic should be considered in patients with resistant oedema who do not respond to an increase in loop diuretic doses.</li> <li>• In patients with acute HF and SBP &gt;110 mmHg, intravenous vasodilators may be considered as initial therapy to improve symptoms and reduce congestion.</li> <li>• Inotropic agents may be considered in patients with SBP &lt;90 mmHg and evidence of hypoperfusion who do not respond to standard treatment, including fluid challenge, to improve peripheral perfusion and maintain end-organ function.</li> <li>• Inotropic agents are not recommended routinely, due to safety concerns, unless the patient has symptomatic hypotension and evidence of hypoperfusion.</li> <li>• A vasopressor, preferably norepinephrine, may be considered in patients with cardiogenic shock to increase blood pressure and vital organ perfusion.</li> <li>• Thromboembolism prophylaxis (e.g. with LMWH) is recommended in patients not already anticoagulated and with no contraindication to anticoagulation, to reduce the risk of deep venous thrombosis and pulmonary embolism.</li> <li>• Routine use of opiates is not recommended, unless in selected patients with severe/intractable pain or anxiety.</li> </ul>
Eighth Joint National Committee (JNC 8):	<ul style="list-style-type: none"> <li>• Pharmacologic treatment should be initiated in patients <math>\geq 60</math> years of age to lower blood pressure at systolic blood pressure <math>\geq 150</math> mm Hg or diastolic blood pressure</li> </ul>

Clinical Guideline	Recommendations
<p><b>2014 Evidence-based Guideline for the Management of High Blood Pressure in Adults (2014)</b><sup>20</sup></p>	<p>≥90 mm Hg and to a goal systolic blood pressure &lt;150 mm Hg and goal diastolic blood pressure &lt;90 mm Hg. Adjustment of treatment is not necessary if treatment results in lower blood pressure and treatment is well tolerated and without adverse effects on health or quality of life.</p> <ul style="list-style-type: none"> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at diastolic blood pressure ≥90 mm Hg to a goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥150 mm Hg to a goal diastolic blood pressure &lt;140 mm Hg.</li> <li>• For patients ≥18 years of age with chronic kidney disease or diabetes, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥140 mm Hg or diastolic blood pressure ≥90 mm Hg and to a goal systolic blood pressure &lt;140 mm Hg and goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• Initial antihypertensive treatment for the general nonblack population, including those with diabetes, should include thiazide-type diuretic, calcium channel blocker (CCB), ACE inhibitor, or ARB.</li> <li>• Initial antihypertensive treatment for the general black population, including those with diabetes, should include thiazide-type diuretic or CCB.</li> <li>• For patients ≥18 years of age with chronic kidney disease regardless of race or diabetes status, initial (or add-on) treatment should include an ACE inhibitor or ARB to improve kidney outcomes.</li> <li>• The main goal of antihypertensive treatment is to attain and maintain goal blood pressure.</li> <li>• If goal blood pressure is not attained within a month of treatment, the dose of the initial drug should be increased or second drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• If goal is not achieved with two drugs, a third drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• An ACE inhibitor and ARB should not be used together.</li> <li>• Antihypertensive classes can be used if the patient is unable to achieve goal blood pressure with three agents or had a contraindication to a preferred class.</li> <li>• If blood pressure is not able to be achieved or in complicated patients, referral to a hypertension specialist may be indicated.</li> </ul>
<p><b>International Society of Hypertension: Global Hypertension Practice Guidelines (2020)</b><sup>21</sup></p>	<p><u>Lifestyle modifications</u></p> <ul style="list-style-type: none"> <li>• Lifestyle modification is the first line of antihypertensive treatment.</li> <li>• Salt reduction: Reduce salt added when preparing foods, and at the table. Avoid or limit consumption of high salt foods such as soy sauce, fast foods and processed food including breads and cereals high in salt.</li> <li>• Healthy diet: Eating a diet that is rich in whole grains, fruits, vegetables, polyunsaturated fats and dairy products and reducing food high in sugar, saturated fat and trans fats, such as the DASH diet.</li> <li>• Healthy drinks: Moderate consumption of coffee, green and black tea. Other beverages that can be beneficial include karkadé (hibiscus) tea, pomegranate juice, beetroot juice and cocoa.</li> <li>• Moderation of alcohol consumption: The recommended daily limit for alcohol consumptions is 2 standard drinks for men and 1.5 for women (10 g alcohol/standard drink). Avoid binge drinking.</li> <li>• Weight reduction: Body weight control is indicated to avoid obesity. Particularly abdominal obesity should be managed. Ethnic-specific cut-offs for BMI and waist circumference should be used. Alternatively, a waist-to-height ratio &lt;0.5 is recommended for all populations.</li> <li>• Smoking cessation: Smoking is a major risk factor for cardiovascular disease (CVD), COPD and cancer. Smoking cessation and referral to smoking cessation</li> </ul>

Clinical Guideline	Recommendations
	<p>programs are advised.</p> <ul style="list-style-type: none"> <li>• Regular physical activity: Studies suggest that regular aerobic and resistance exercise may be beneficial for both the prevention and treatment of hypertension. Moderate intensity aerobic exercise (walking, jogging, cycling, yoga, or swimming) for 30 minutes on five to seven days per week. Strength training also can help reduce blood pressure. Performance of resistance/strength exercises on two to three days per week.</li> <li>• Reduce stress and induce mindfulness: Stress should be reduced and mindfulness or meditation introduced into the daily routine.</li> <li>• Reduce exposure to air pollution and cold temperature: Evidence from studies support a negative effect of air pollution on blood pressure in the long-term.</li> </ul> <p><b>Pharmacological Treatment</b></p> <ul style="list-style-type: none"> <li>• Ideal characteristics of drug treatment           <ul style="list-style-type: none"> <li>○ Treatments should be evidence-based in relation to morbidity/mortality prevention.</li> <li>○ Use a once-daily regimen which provides 24-hour blood pressure control.</li> <li>○ Treatment should be affordable and/or cost-effective relative to other agents.</li> <li>○ Treatments should be well-tolerated.</li> <li>○ Evidence of benefits of use of the medication in populations to which it is to be applied.</li> </ul> </li> <li>• General scheme for drug treatment           <ul style="list-style-type: none"> <li>○ Lifestyle modification is the first line of antihypertensive treatment.</li> <li>○ Grade 1 hypertension (BP 140 to 159/ 90 to 99): Immediate drug treatment in high-risk patients or those with CVD, chronic kidney disease (CKD), diabetes mellitus (DM), or hypertension-mediated organ damage (HMOD). Drug treatment after three to six months of lifestyle intervention if BP still not controlled in low to moderate risk patients.</li> <li>○ Grade 2 hypertension (BP <math>\geq</math>160/100): Immediate drug treatment in all patients.</li> </ul> </li> <li>• Core drug-treatment strategy           <ul style="list-style-type: none"> <li>○ Step 1: Dual low-dose combination (ACE inhibitor or ARB plus dihydropyridine-calcium channel blockers (DHP-CCB)); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance; consider ACE/ARB plus DHP-CCB or DHP-CCB plus thiazide-like diuretics in black patients.</li> <li>○ Step 2: Dual full-dose combination (ACE inhibitor or ARB plus DHP-CCB); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance.</li> <li>○ Step 3: Triple combination (ACE/ARB plus DHP-CCB plus thiazide-like diuretic).</li> <li>○ Step 4, resistant hypertension: triple combination plus spironolactone or other drug, alternatives include amiloride, doxazosin, eplerenone, clonidine, or <math>\beta</math>-blocker. Caution with spironolactone or other potassium sparing diuretics when estimated GFR <math>&lt;</math>45 mL/min/1.73m<sup>2</sup> or K<sup>+</sup> <math>&gt;</math>4.5 mmol/L.</li> <li>○ Consider <math>\beta</math>-blockers at any treatment step when there is a specific indications for their use, e.g., heart failure, angina, post-MI, atrial fibrillation, or younger women planning pregnancy or pregnant.</li> </ul> </li> </ul>
<p>Hypertension Canada: 2020 Guidelines for</p>	<p>Indications for drug therapy for adults with hypertension without compelling indications for specific agents</p>

Clinical Guideline	Recommendations
<p><b>the Prevention, Diagnosis, Risk Assessment, and Treatment of Hypertension in Adults and Children (2020)</b><sup>22</sup></p>	<ul style="list-style-type: none"> <li>• Antihypertensive therapy should be prescribed for average diastolic blood pressure (DBP) measurements of <math>\geq 100</math> mmHg or average systolic blood pressure (SBP) measurements of <math>\geq 160</math> mmHg in patients without macrovascular target organ damage or other cardiovascular risk factors.</li> <li>• Antihypertensive therapy should be strongly considered for average DPB readings <math>\geq 90</math> mmHg or for average SBP readings <math>\geq 140</math> mmHg in the presence of macrovascular target organ damage or other independent cardiovascular risk factors.</li> <li>• For high-risk patients, aged 50 years or older, with SBP levels <math>\geq 130</math> mmHg, intensive management to target a SBP <math>&lt; 120</math> mmHg should be considered. Patient selection for intensive management is recommended and caution should be taken in certain high-risk groups.</li> </ul> <p><u>Indications for drug therapy for adults with diastolic and with or without systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be with either monotherapy or single pill combination (SPC).             <ul style="list-style-type: none"> <li>○ Recommended monotherapy choices are:                 <ul style="list-style-type: none"> <li>▪ A thiazide/thiazide-like diuretic, with longer-acting diuretics preferred;</li> <li>▪ A <math>\beta</math>-blocker (in patients <math>&lt; 60</math> years of age);</li> <li>▪ An angiotensin-converting enzyme (ACE) inhibitor (in nonblack patients);</li> <li>▪ An angiotensin receptor blocker (ARB); or</li> <li>▪ A long-acting calcium channel blocker (CCB).</li> </ul> </li> <li>○ Recommended SPC choices are those in which an ACE inhibitor is combined with a CCB, ARB with a CCB, or ACE inhibitor or ARB with a diuretic.</li> <li>○ Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> </ul> </li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line choices. Useful choices include a thiazide/thiazide-like diuretic or CCB with either: ACE inhibitor, ARB, or <math>\beta</math>-blocker. Caution should be exercised in combining a nondihydropyridine CCB and a <math>\beta</math>-blocker. The combination of an ACE inhibitor and an ARB is not recommended.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other antihypertensive drugs may be added.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated hypertension; <math>\beta</math>-blockers are not recommended as first-line therapy for uncomplicated hypertension in patients <math>\geq 60</math> years of age; and ACE inhibitors are not recommended as first-line therapy for uncomplicated hypertension in black patients. However, these agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Indications for drug therapy for adults with isolated systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be single-agent therapy with a thiazide/thiazide-like diuretic, a long-acting dihydropyridine CCB, or an ARB. If there are adverse effects, another drug from this group should be substituted. Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line options.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other classes of drugs (such as <math>\alpha</math>-blockers, ACE</li> </ul>

Clinical Guideline	Recommendations
	<p>inhibitors, centrally acting agents, or nondihydropyridine CCBs) may be combined or substituted.</p> <ul style="list-style-type: none"> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated isolated systolic hypertension; and <math>\beta</math>-blockers are not recommended as first-line therapy for isolated systolic hypertension in patients <math>\geq 60</math> years of age. However, both agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Guidelines for hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• For most hypertensive patients with CAD, an ACE inhibitor or ARB is recommended.</li> <li>• For hypertensive patients with CAD, but without coexisting systolic heart failure, the combination of an ACE inhibitor and ARB is not recommended.</li> <li>• For high-risk hypertensive patients, when combination therapy is being used, choices should be individualized. The combination of an ACE inhibitor and a dihydropyridine CCB is preferable to an ACE inhibitor and a thiazide/thiazide-like diuretic in selected patients.</li> <li>• For patients with stable angina pectoris but without previous heart failure, myocardial infarction, or coronary artery bypass surgery, either a <math>\beta</math>-blocker or CCB can be used as initial therapy.</li> <li>• Short-acting nifedipine should not be used.</li> <li>• When decreasing SBP to target levels in patients with established CAD (especially if isolated systolic hypertension is present), be cautious when the DBP is <math>\leq 60</math> mmHg because of concerns that myocardial ischemia might be exacerbated, especially in patients with left ventricular hypertrophy (LVH).</li> </ul> <p><u>Guidelines for patients with hypertension who have had a recent myocardial infarction</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should include a <math>\beta</math>-blocker as well as an ACE inhibitor.</li> <li>• An ARB can be used if the patient is intolerant of an ACE inhibitor.</li> <li>• CCBs may be used in patients after myocardial infarction when <math>\beta</math>-blockers are contraindicated or not effective. Nondihydropyridine CCBs should not be used when there is heart failure, evidenced by pulmonary congestion on examination or radiography.</li> </ul> <p><u>Treatment of hypertension in association with heart failure</u></p> <ul style="list-style-type: none"> <li>• In patients with systolic dysfunction (ejection fraction <math>&lt; 40\%</math>), ACE inhibitors and <math>\beta</math>-blockers are recommended for initial therapy. Aldosterone antagonists (mineralocorticoid receptor antagonists) may be combined in treatment for patients with a recent cardiovascular hospitalization, acute myocardial infarction, elevated B-type natriuretic peptide or N-terminal pro-B-type natriuretic peptide level, or New York Heart Association (NYHA) Class II-IV symptoms. Careful monitoring for hyperkalemia is recommended when combining an aldosterone antagonist with ACE inhibitor or ARB treatment. Other diuretics are recommended as additional therapy if needed. Beyond considerations of BP control, doses of ACE inhibitors or ARBs should be titrated to those reported to be effective in trials unless adverse effects become manifest.</li> <li>• An ARB is recommended if ACE inhibitors are not tolerated.</li> <li>• A combination of hydralazine and isosorbide dinitrate is recommended if ACE inhibitors and ARBs are contraindicated or not tolerated.</li> <li>• For hypertensive patients whose BP is not controlled, an ARB may be combined with an ACE inhibitor and other antihypertensive drug treatment. Careful monitoring should be used if combining an ACE inhibitor and an ARB because of potential adverse effects such as hypotension, hyperkalemia, and worsening</li> </ul>

Clinical Guideline	Recommendations
	<p>renal function. Additional therapies may also include dihydropyridine CCBs.</p> <ul style="list-style-type: none"> <li>• An angiotensin receptor-neprilysin inhibitor (ARNI) should be used in place of an ACE inhibitor or ARB for patients with HFrEF (&lt;40%) who remain symptomatic despite treatment with appropriate dose of guideline directed HF therapy. Eligible patients must have a serum potassium &lt;5.2 mmol/L, an eGFR ≤30 mL/min/1.73m<sup>2</sup> and close surveillance of serum potassium and creatinine.</li> </ul> <p><u>Treatment of hypertension in association with stroke</u></p> <ul style="list-style-type: none"> <li>• BP management in acute ischemic stroke (onset to 72 hours)             <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> <li>• BP management after acute ischemic stroke             <ul style="list-style-type: none"> <li>○ Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack.</li> <li>○ After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently &lt;140/90 mmHg.</li> <li>○ Treatment with an ACE inhibitor and thiazide/thiazide-like diuretic combination is preferred.</li> <li>○ For patients with stroke, the combination of an ACE inhibitor and ARB is not recommended.</li> </ul> </li> <li>• BP management in hemorrhagic stroke (onset to 72 hours)             <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> </ul> <p><u>Treatment of hypertension in association with LVH</u></p> <ul style="list-style-type: none"> <li>• Hypertensive patients with LVH should be treated with antihypertensive therapy to decrease the rate of subsequent cardiovascular events.</li> <li>• The choice of initial therapy can be influenced by the presence of LVH. Initial therapy can be drug treatment using ACE inhibitors, ARBs, long-acting CCBs, or thiazide/thiazide-like diuretics. Direct arterial vasodilators such as hydralazine or minoxidil should not be used.</li> </ul> <p><u>Treatment of hypertension in association with nondiabetic chronic kidney disease</u></p> <ul style="list-style-type: none"> <li>• Individualize BP targets in patients with chronic kidney disease. Consider intensive targets (SBP &lt;120 mmHg) in appropriate patients.</li> <li>• For patients with hypertension and proteinuric chronic kidney disease (urinary protein &gt;150 mg per 24 hours or albumin to creatinine ratio &gt;30 mg/mmol), initial therapy should be an ACE inhibitor or an ARB if there is intolerance to ACE inhibitors.</li> <li>• In most cases, combination therapy with other antihypertensive agents might be needed to reach target BP levels.</li> <li>• The combination of an ACE inhibitor and ARB is not recommended for patients with nonproteinuric chronic kidney disease.</li> </ul> <p><u>Treatment of hypertension in association with renovascular disease</u></p> <ul style="list-style-type: none"> <li>• Patients with hypertension attributable to atherosclerotic renal artery stenosis should be primarily medically managed because renal angioplasty and stenting offers no benefit over optimal medical therapy alone.</li> <li>• Renal artery angioplasty and stenting for atherosclerotic hemodynamically significant renal artery stenosis could be considered for patients with uncontrolled hypertension resistant to maximally tolerated pharmacotherapy, progressive renal function loss, and acute pulmonary edema.</li> <li>• Patients with confirmed renal fibromuscular dysplasia (FMD) should be referred to a hypertension specialist.</li> <li>• Renal artery angioplasty without stenting is recommended for treatment of FMD-related renal artery stenosis. Stenting is not recommended unless needed because of a periprocedural dissection. Surgical revascularization should be considered in</li> </ul>

Clinical Guideline	Recommendations
	<p>cases of complex lesions less amenable to angioplasty, stenosis associated with complex aneurysm, and restenosis despite two unsuccessful attempts of angioplasty.</p> <p><u>Treatment of hypertension in association with diabetes mellitus</u></p> <ul style="list-style-type: none"> <li>• Persons with diabetes mellitus should be treated to attain SBP of &lt;130 mmHg and DBP of &lt;80 mmHg.</li> <li>• For persons with cardiovascular or kidney disease, including microalbuminuria, or with cardiovascular risk factors in addition to diabetes and hypertension, an ACE inhibitor or an ARB is recommended as initial therapy.</li> <li>• For persons with diabetes and hypertension not included in other guidelines in this section, appropriate choices include (in alphabetical order): ACE inhibitors, ARBs, dihydropyridine CCBs, and thiazide/thiazide-like diuretics.</li> <li>• If target BP levels are not achieved with standard-dose monotherapy, additional antihypertensive therapy should be used. For persons in whom combination therapy with an ACE inhibitor is being considered, a dihydropyridine CCB is preferable to a thiazide/thiazide-like diuretic.</li> </ul> <p><u>Resistant hypertension</u></p> <ul style="list-style-type: none"> <li>• Resistant hypertension is defined as BP above target despite three or more BP-lowering drugs at optimal doses preferably including a diuretic (and usually a renin-angiotensin-aldosterone system blocker and a CCB).</li> <li>• Accurate office and out-of-office BP measurement is essential.</li> <li>• Other reasons for apparent resistant hypertension should be eliminated before diagnosing true resistant hypertension, including nonadherence, white coat effect, and secondary hypertension.</li> <li>• Pharmacotherapy with the additional use of spironolactone, bisoprolol, doxazosin, amiloride, eplerenone, or clonidine with the baseline regimen decreases BP significantly, with the greatest BP-lowering shown with spironolactone.</li> <li>• Patients with resistant hypertension should be referred to providers with expertise in diagnosis and management of hypertension.</li> </ul> <p><u>Hypertension and pediatrics</u></p> <ul style="list-style-type: none"> <li>• BP should be measured regularly in children three years of age or older; the auscultatory method is the gold-standard at present.</li> <li>• Initial therapy should be monotherapy, with an ACE inhibitor or ARB (not first-line in black children), or a long-acting dihydropyridine CCB.</li> <li>• The treatment goal is systolic and diastolic office BP and/or ABPM &lt; 95th percentile or &lt;90<sup>th</sup> percentile in children with risk factors or target organ damage.</li> <li>• Complex cases should be referred to an expert in pediatric hypertension.</li> </ul> <p><u>Hypertension and pregnancy</u></p> <ul style="list-style-type: none"> <li>• Up to 7% of pregnancies are complicated by a hypertensive disorder of pregnancy, and approximately 5% of women will have chronic hypertension when they become pregnant.</li> <li>• The prevalence of hypertension in pregnancy is expected to increase with women becoming pregnant later in their reproductive years and the increasing prevalence of cardiovascular comorbidities such as increased preconception body mass index and maternal diabetes.</li> <li>• The possibility of pregnancy should be considered when managing women with hypertension who are of reproductive age.</li> <li>• Preconception counselling should be offered to all women with hypertension who are considering pregnancy.</li> <li>• ACE inhibitor and ARB therapy should be avoided before conception and during</li> </ul>

Clinical Guideline	Recommendations
	<p>pregnancy unless there is a compelling indication for their use (i.e., proteinuric kidney disease).</p> <ul style="list-style-type: none"> <li>• Hypertension during pregnancy can increase the risk of adverse maternal and fetal outcomes, including an increased risk of preeclampsia, placental abruption, prematurity, small for gestational age infants, stillbirth, and maternal renal and retinal injury, thus generally requires involvement of an interdisciplinary team including obstetrical care providers.</li> <li>• Antihypertensive therapy is recommended for average SBP measurements of <math>\geq 140</math> mmHg or DBP measurements of <math>\geq 90</math> mmHg in pregnant women with chronic hypertension, gestational hypertension, or preeclampsia. Initial antihypertensive therapy should be monotherapy from the following first-line drugs: oral labetalol, oral methyldopa, long-acting oral nifedipine, or other oral b-blockers (acebutolol, metoprolol, pindolol, and propranolol). Other antihypertensive drugs can be considered as second-line drugs including: clonidine, hydralazine, and thiazide diuretics.</li> <li>• Women with severe hypertension with SBP <math>\geq 160</math> mmHg or DBP <math>\geq 110</math> mmHg in pregnancy or postpartum require urgent antihypertensive therapy because it is considered an obstetrical emergency.</li> <li>• Antihypertensive drugs used in breastfeeding women include: labetalol, methyldopa, long-acting nifedipine, enalapril, or captopril.</li> </ul>
<p>European Society of Hypertension/ European Society of Cardiology: <b>2018 Guidelines for the management of arterial hypertension (2018)</b><sup>23</sup></p>	<p><u>Treatment strategies and choice of antihypertensive drugs</u></p> <ul style="list-style-type: none"> <li>• Diuretics (including thiazides, chlorthalidone, and indapamide), <math>\beta</math>-blockers, calcium channel blocker (CCB), angiotensin-converting enzyme (ACE) inhibitors, and angiotensin receptor blockers (ARBs) are all suitable for the initiation and maintenance of antihypertensive treatment, either as monotherapy or in some combinations.</li> <li>• Some agents should be considered as the preferential choice in specific conditions because used in trials in those conditions or because of greater effectiveness in specific types of organ damage. Preferred combinations should comprise a renin-angiotensin system (RAS) blocker (either an ACE inhibitor or an ARB) with a CCB or diuretic.</li> <li>• It is recommended that beta-blockers are combined with any of the other major drug classes when there are specific clinical situations, e.g. angina, post-myocardial infarction, heart failure, or heart rate control.</li> <li>• Initiation of antihypertensive therapy with a two-drug combination may be considered in patients with markedly high baseline blood pressure (BP) or at high cardiovascular (CV) risk.</li> <li>• The combination of two antagonists of the RAS is not recommended and should be discouraged.</li> <li>• Other drug combinations should be considered and probably are beneficial in proportion to the extent of BP reduction. However, combinations that have been successfully used in trials may be preferable.</li> <li>• Combinations of two antihypertensive drugs at fixed doses in a single tablet may be recommended and favored, because reducing the number of daily pills improves adherence, which is low in patients with hypertension. Exceptions are frail older patients and those at low risk and with grade one hypertension (particularly if systolic BP is <math>&lt; 150</math> mmHg).</li> <li>• It is recommended that if BP is not controlled with a three-drug combination, treatment should be increased by the addition of spironolactone or, if not tolerated, other diuretics such as amiloride or higher doses of other diuretics, a beta-blocker, or an alpha-blocker.</li> </ul> <p><u>Treatment strategies in white-coat and masked hypertension</u></p> <ul style="list-style-type: none"> <li>• In white-coat hypertensives without additional risk factors, therapeutic intervention may be limited to lifestyle changes only, but this decision should be</li> </ul>

Clinical Guideline	Recommendations
	<p>accompanied by close follow-up.</p> <ul style="list-style-type: none"> <li>• In white-coat hypertensives with a higher CV risk or hypertension-mediated organ damage, drug treatment may be considered in addition to lifestyle changes.</li> <li>• In masked hypertension, both lifestyle measures and antihypertensive drug treatment should be considered, because this type of hypertension has been consistently found to have a CV risk very close to that of in- and out-of-office hypertension.</li> <li>• Antihypertensive drug up-titration should be considered in treated patients whose out-of-office BP is not controlled (i.e., masked uncontrolled hypertension), because of the high CV risk of these patients.</li> </ul> <p><u>Antihypertensive treatment strategies in the elderly</u></p> <ul style="list-style-type: none"> <li>• It is recommended that older patients (<math>\geq 65</math> years) are treated with the same recommendations in non-older patient population. In very old patients (<math>\geq 80</math> years), it may be appropriate to initiate treatment with monotherapy.</li> <li>• In all older patients, when combination therapy is used, it is recommended that this is initiated at the lowest available doses. In all older patients, and especially very old or frail patients, the possible occurrence of postural BP should be closely monitored and symptoms of possible hypotensive episodes checked by ambulatory blood pressure monitoring.</li> <li>• Unless required for concomitant diseases, loop diuretics and alpha-blockers should be avoided because of their association with injurious falls.</li> <li>• Renal function should be frequently assessed to detect possible increases in serum creatinine and reductions in estimated glomerular filtration rate (eGFR) as a result of BP-related reductions in renal perfusion.</li> <li>• When treated, BP should be lowered to a systolic value of 130 to 139 mmHg and a diastolic value of <math>&lt; 80</math> mmHg if tolerated. Treated values of <math>&lt; 130</math> mmHg should be avoided.</li> </ul> <p><u>Treatment strategies in hypertensive women</u></p> <ul style="list-style-type: none"> <li>• Hormone therapy and selective estrogen receptor modulators are not recommended and should not be used for primary or secondary prevention of CVD.</li> <li>• In women with gestational hypertension, pre-existing hypertension superimposed by gestational hypertension, or with hypertension and subclinical organ damage or symptoms, initiation of drug treatments is recommended when SBP is <math>\geq 140</math> mmHg or DBP <math>\geq 90</math> mmHg. In all other cases, initiation of drug treatment is recommended when SBP is <math>\geq 150</math> mmHg or DBP is <math>\geq 95</math> mmHg.</li> <li>• Methyldopa, labetalol, and CCBs are recommended as the drugs of choice for the treatment of hypertension in pregnancy.</li> <li>• ACE inhibitors, ARBs, or direct renin inhibitors are not recommended during pregnancy.</li> <li>• SBP <math>\geq 170</math> mmHg or DBP <math>\geq 110</math> mmHg in a pregnant woman is an emergency, and admission to hospital is recommended.</li> <li>• In severe hypertension, drug treatment with intravenous (IV) labetalol, oral methyldopa, or nifedipine is recommended.</li> <li>• The recommended treatment for hypertensive crisis is IV labetalol or nicardipine and magnesium.</li> <li>• In pre-eclampsia associated with pulmonary edema, nitroglycerin given as an IV infusion is recommended.</li> <li>• In women with gestational hypertension or mild-pre-eclampsia, delivery is recommended at 37 weeks.</li> <li>• It is recommended to expedite delivery in pre-eclampsia with adverse conditions, such as visual disturbances or hemostatic disorders</li> <li>• In women at high risk of pre-eclampsia, provided they are at low risk of</li> </ul>

Clinical Guideline	Recommendations
	<p>gastrointestinal hemorrhage, treatment with low dose aspirin from 12 weeks until delivery may be considered.</p> <ul style="list-style-type: none"> <li>• Methyldopa, labetalol, and nifedipine should be considered preferential antihypertensive drugs in pregnancy. Intravenous labetalol or infusion of nitroprusside should be considered in case of emergency (pre-eclampsia).</li> </ul> <p><u>Treatment strategies in patients with diabetes</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive drug treatment is recommended for people with diabetes when office BP is <math>\geq 140/90</math> mmHg.</li> <li>• A SBP goal <math>&lt; 130</math> mmHg is recommended in patients with diabetes and <math>&lt; 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg.</li> <li>• In older people, the target SBP range is 130 to 139 mmHg.</li> <li>• The DBP target in patients with diabetes is recommended to be <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• It is recommended to initiate treatment with a combination of a RAS blocker with a CCB or thiazide/thiazide-like diuretic.</li> <li>• It is recommended that individual drug choice takes comorbidities into account.</li> <li>• Simultaneous administration of two blockers of the RAS is not recommended and should be avoided in patients with diabetes.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with nephropathy</u></p> <ul style="list-style-type: none"> <li>• In patients with diabetic and non-diabetic CKD, it is recommended that an office BP of <math>\geq 140/90</math> mmHg be treated with lifestyle advice and BP-lowering medication.</li> <li>• In patients with diabetic or non-diabetic CKD, it is recommended to lower SBP to a range of 130 to 139 mmHg. And individualized treatments should be considered according to its tolerability and impact on renal function and electrolytes.</li> <li>• A combination of a RAS blocker with a CCB or a diuretic is recommended as initial therapy.</li> <li>• RAS blockers are more effective in reducing albuminuria than other antihypertensive agents, and are indicated in hypertensive patients in the presence of microalbuminuria or overt proteinuria.</li> <li>• Combination of two RAS blockers, though potentially more effective in reducing proteinuria, is not recommended.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with cerebrovascular disease</u></p> <ul style="list-style-type: none"> <li>• In patients with acute intracerebral hemorrhage, immediate BP lowering is not recommended for patients with SBP <math>&lt; 220</math> mmHg. In patients with SBP <math>\geq 220</math> mmHg, care acute BP lowering with IV therapy to <math>&lt; 180</math> mmHg should be considered.</li> <li>• In acute ischemic stroke, routine BP lowering with antihypertensive therapy is not recommended with the exceptions with the exceptions: in patients with acute ischemic stroke who are eligible for IV thrombolysis, BP should be carefully lowered and maintained at <math>&lt; 180/105</math> mmHg for at least the first 24 hours after thrombolysis; In patients with markedly elevated BP who do not receive fibrinolysis, drug therapy may be considered, based on clinical judgement, to reduce BP by 15% during the first 24 hours after the stroke onset.</li> <li>• In hypertensive patients with an acute cerebrovascular event, antihypertensive treatment is recommended immediately for transient ischemic attack (TIA) and after several days in ischemic stroke.</li> <li>• In all hypertensive patients with ischemic stroke or TIA, an SBP target range of 120 to 130 mmHg should be considered.</li> <li>• The recommended antihypertensive drug treatment strategy for stroke prevention is a RAS blocker plus a CCB or a thiazide-like diuretic.</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Therapeutic strategies in hypertensive patients with heart failure (HF) or left ventricular hypertrophy (LVH)</u></p> <ul style="list-style-type: none"> <li>• In hypertensive patients with heart failure (with reduced or preserved ejection fraction), BP-lowering treatment should be considered if <math>\geq 140/90</math> mmHg.</li> <li>• In patients with HFrEF, it is recommended that BP-lowering treatment comprises an ACE inhibitor or ARB, and a beta-blocker and a diuretic and/or mineralocorticoid receptor antagonist (MRA) if required.</li> <li>• Dihydropyridine CCBs may be added if BP control is not achieved.</li> <li>• In patients with HFpEF, BP treatment threshold and target values should be the same as for HFrEF).</li> <li>• Because no specific drug has proven its superiority, all major agents can be used.</li> <li>• In all patients with LVH, it is recommended to treat with a RAS blocker or in combination with a CCB or diuretic and SBP should be lowered to a range of 120 to 130 mmHg.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• In patients with CAD receiving BP-lowering drugs, it is recommended to target SBP to <math>\leq 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg. In older patients, the target is an SBP range of 130 to 140 mmHg. The target DBP is <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• In hypertensive patients with a history of myocardial infarction, beta-blockers and RAS blockers are recommended as part of treatment.</li> <li>• In patients with asymptomatic angina, beta-blockers and/or CCBs are recommended.</li> </ul>
<p>National Institute for Health and Clinical Excellence: <b>Hypertension in adults: diagnosis and management (2019)</b><sup>24</sup></p>	<p><u>Choosing antihypertensive drug treatment (for people with or without type II diabetes)</u></p> <ul style="list-style-type: none"> <li>• Where possible, recommend treatment with drugs taken only once a day.</li> <li>• Prescribe non-proprietary drugs where these are appropriate and minimize cost.</li> <li>• Offer people with isolated systolic hypertension (systolic blood pressure <math>\geq 160</math> mmHg) the same treatment as people with both raised systolic and diastolic blood pressure.</li> <li>• Offer antihypertensive drug treatment to women of child-bearing potential with diagnosed hypertension in line with recommendations in this guideline. For women considering pregnancy or who are pregnant or breastfeeding, manage hypertension in line with the recommendations on Management of pregnancy with chronic hypertension and Breastfeeding in 'Hypertension in pregnancy'.</li> <li>• When choosing antihypertensive drug treatment for adults of black African or African-Caribbean family origin, consider an angiotensin II receptor blocker, in preference to an angiotensin-converting enzyme inhibitor.</li> </ul> <p><u>Step one treatment</u></p> <ul style="list-style-type: none"> <li>• Patients <math>&lt; 55</math> years of age should be offered a step one antihypertensive with an angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB).</li> <li>• Offer an ACE inhibitor or an ARB to adults starting step 1 antihypertensive treatment who have type II diabetes and are of any age or family origin or those aged <math>&lt; 55</math> years but not of black African or African-Caribbean family origin.</li> <li>• If an ACE inhibitor is not tolerated, offer an ARB.</li> <li>• Do not combine an ACE inhibitor with an ARB for the treatment of hypertension.</li> <li>• Offer a calcium channel blocker (CCB) to adults starting step 1 antihypertensive treatment who are <math>&gt; 55</math> years of age and do not have diabetes and are of black African or African-Caribbean family origin and do not have type II diabetes and of any age.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• If a CCB is not suitable, for example because of edema or intolerance, or if there is evidence of heart failure or a high risk of heart failure, offer a thiazide-like diuretic.</li> <li>• If diuretic treatment is to be initiated or changed, offer a thiazide-like diuretic, such as indapamide in preference to a conventional thiazide diuretic such as bendroflumethiazide or hydrochlorothiazide.</li> <li>• For adults with hypertension who are already receiving treatment with bendroflumethiazide or hydrochlorothiazide, who have stable, well-controlled blood pressure, continue with their treatment.</li> </ul> <p><u>Step two treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering next step treatment for hypertension discuss with the person if they are taking their medicine as prescribed and support adherence in line with NICE's guideline on "Medicines adherence: involving patients decisions about prescribed medicines and supporting adherence".</li> <li>• If hypertension is not controlled with a step one treatment of an ACE inhibitor or ARB, offer choice of one of the following drugs in addition to the step one treatment: a CCB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults taking step one treatment of a CCB, offer the choice of one of the following drugs in addition to the step one treatment: an ACE inhibitor or an ARB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults of black African or African–Caribbean family origin who do not have type 2 diabetes taking step one treatment, consider an ARB, in preference to an ACE inhibitor, in addition to step one treatment.</li> </ul> <p><u>Step three treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering step three treatment, review the person's medications to ensure they are being taken at the optimal doses and discuss adherence (see recommendation under step two).</li> <li>• If hypertension is not controlled in adults taking step two treatment, offer a combination of an ACE inhibitor or ARB and a CCB and a thiazide-like diuretic.</li> </ul> <p><u>Step four treatment</u></p> <ul style="list-style-type: none"> <li>• If hypertension is not controlled in adults taking the optimal tolerated doses of an ACE inhibitor or an ARB plus a CCB and a thiazide-like diuretic, regard them as having resistant hypertension.</li> <li>• Before considering further treatment for a person with resistant hypertension, confirm elevated clinic blood pressure measurements using ambulatory or home blood pressure recordings, assess for postural hypotension, and discuss adherence.</li> <li>• For people with confirmed resistant hypertension, consider adding a fourth antihypertensive drug as step four treatment or seeking specialist advice.</li> <li>• Consider further diuretic therapy with low-dose spironolactone for adults with resistant hypertension starting step four treatment who have a blood potassium level of 4.5 mmol/l or less. Use particular caution in people with a reduced estimated glomerular filtration rate because they have an increased risk of hyperkalemia.</li> <li>• When using further diuretic therapy for step four treatment of resistant hypertension, monitor blood sodium and potassium and renal function within one month of starting treatment and repeat as needed thereafter.</li> <li>• Consider an alpha-blocker or beta-blocker for adults with resistant hypertension starting step four treatment who have a blood potassium level of more than 4.5 mmol/l.</li> <li>• If blood pressure remains uncontrolled in people with resistant hypertension taking the optimal tolerated doses of four drugs, seek specialist advice.</li> </ul>

Clinical Guideline	Recommendations
<p>International Society on Hypertension in Blacks: <b>Management of High Blood Pressure in Blacks (2010)</b><sup>25</sup></p>	<ul style="list-style-type: none"> <li>• To attain and maintain blood pressure (BP) below target levels, multiple antihypertensive drugs will be required in most hypertensive blacks.</li> <li>• Use of two-drug combination therapy when SBP is &gt;15 mm Hg and/or DBP is &gt;10 mm Hg above goal levels is increasingly recommended as first-line therapy.</li> <li>• Two-drug regimens have generally contained a thiazide-type diuretic; however, the combination of a calcium channel blocker (CCB) with either an ACE inhibitor or an ARB has been shown equally efficacious in BP lowering but with demonstrated superiority (CCB+ACE) for hard clinical outcomes compared with the same ACE inhibitor plus a thiazide-type diuretic.</li> <li>• In secondary prevention patients, the combination therapy should include a drug(s) with the appropriate compelling indications.</li> <li>• Certain classes of antihypertensive medications, specifically diuretics and CCBs, lower BP on average more than <math>\beta</math>-blockers and renin-angiotensin system (RAS) blockers in black patients when used as monotherapies.</li> <li>• In the absence of compelling indications, when BP is near goal levels, monotherapy with a diuretic or a CCB is preferred.</li> <li>• Lifestyle modifications should be initiated in all patients with hypertension, whether or not pharmacotherapy is planned.</li> <li>• ACE inhibitors or ARBs are recommended as alternative monotherapy options in the treatment of hypertension in blacks. The rationale for their lower tier monotherapy recommendation is because they have consistently achieved lesser average reductions in BP relative to that observed with monotherapy using either a diuretic or CCB.</li> </ul>
<p>Kidney Disease Improving Clinical Outcomes Group; <b>KDIGO Clinical Practice Guideline for the Management of Blood Pressure in Chronic Kidney Disease (2021)</b><sup>26</sup></p>	<p><u>Blood pressure measurement</u></p> <ul style="list-style-type: none"> <li>• The Work Group recommends standardized office blood pressure (BP) measurement in preference to routine office BP measurements for the management of high BP in adults.</li> <li>• The Work Group suggests that out-of-office BP measurements with ambulatory BP monitoring (ABPM) or home BP monitoring (HBPM) be used to complement standardized office BP readings for the management of high BP.</li> </ul> <p><u>Lifestyle interventions for lowering BP in patients with chronic kidney disease (CKD) not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>• The Work Group suggests targeting a sodium intake &lt;2 grams of sodium per day (or &lt;90 mmol of sodium per day, or &lt;5 grams of sodium chloride per day) in patients with high BP and CKD.</li> <li>• The Work Group suggests that patients with high BP and CKD be advised to undertake moderate-intensity physical activity for a cumulative duration of at least 150 minutes per week, or to a level compatible with their cardiovascular and physical tolerance.</li> </ul> <p><u>BP management in patients with CKD, with or without diabetes, not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>• The Work Group suggests that adults with high BP and CKD be treated with a target systolic BP (SBP) of &lt;120 mmHg, when tolerated, using standardized office BP measurement.</li> <li>• The Work Group recommends starting renin-angiotensin-system inhibitors (RASi) (angiotensin-converting enzyme inhibitor [ACEi] or angiotensin II receptor blocker [ARB]) for people with high BP, CKD, and severely increased albuminuria without diabetes.</li> <li>• The Work Group suggests starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately increased albuminuria without diabetes.</li> <li>• The Work Group recommends starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately-to-severely increased albuminuria with diabetes.</li> <li>• The Work Group recommends avoiding any combination of ACEi, ARB, and</li> </ul>

Clinical Guideline	Recommendations
	<p>direct renin inhibitor (DRI) therapy in patients with CKD, with or without diabetes.</p> <p><u>BP management in kidney transplant recipients</u></p> <ul style="list-style-type: none"> <li>• Treat adult kidney transplant recipients with high BP to a target BP of &lt;130 mmHg systolic and &lt;80 mmHg diastolic using standardized office BP measurement.</li> <li>• The Work Group recommends that a dihydropyridine calcium channel blocker (CCB) or an ARB be used as the first-line antihypertensive agent in adult kidney transplant recipients.</li> </ul> <p><u>BP management in children with CKD</u></p> <ul style="list-style-type: none"> <li>• The Work Group suggests that in children with CKD, 24-hour mean arterial pressure by ABPM should be lowered to &lt;50<sup>th</sup> percentile for age, sex, and height.</li> </ul>
<p>American College of Cardiology/ American Heart Association Task Force: <b>Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults (2017)</b><sup>27</sup></p>	<p><u>Initiation of Blood Pressure (BP) Treatment for Overall Cardiovascular Disease (CVD) Risk</u></p> <ul style="list-style-type: none"> <li>• Use of BP-lowering medications is recommended for secondary prevention of recurrent CVD events in patients with clinical CVD and an average systolic blood pressure (SBP) <math>\geq 130</math> mmHg or an average diastolic blood pressure (DBP) of <math>\geq 80</math> mmHg and for primary prevention in adults with an estimated 10-year atherosclerotic cardiovascular disease (ASCVD) risk of <math>\geq 10\%</math> and an average SBP of <math>\geq 130</math> mmHg or an average <math>\geq 80</math> mmHg.</li> <li>• Use of BP-lowering medication is recommended for primary prevention of CVD in adults with no history of CVD and with an estimated 10-year ASCVD risk <math>&lt; 10\%</math> and an SBP of <math>\geq 140</math> mmHg or a DBP of <math>\geq 90</math> mmHg.</li> <li>• Simultaneous use of an angiotensin converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), and/or renin inhibitor is potentially harmful and is not recommended to treat adults with hypertension.</li> <li>• For adults with confirmed hypertension and known CVD or 10-year ASCVD risk of <math>\geq 10\%</math>, a BP target <math>&lt; 130/80</math> mmHg is recommended. For adults with confirmed hypertension without additional markers of increased CVD risk, a BP target <math>&lt; 130/80</math> mmHg may be reasonable.</li> <li>• For initiation of antihypertensive drug therapy, first-line agents include thiazide diuretics, calcium channel blockers (CCBs), and ACE inhibitors or ARBs.</li> <li>• Initiation of antihypertensive drug therapy with two first-line agents of different classes, either as separate agents or in a fixed-dose combination, is recommended in adults with stage 2 hypertension and an average BP <math>&gt; 20/10</math> mmHg above their BP target.</li> <li>• Initiation of antihypertensive drug therapy with a single antihypertensive drug is reasonable in adults with stage 1 hypertension and BP goal <math>&lt; 130/80</math> mmHg with dosage titration and sequential addition of other agents to achieve the BP target.</li> </ul> <p><u>Stable Ischemic Heart Disease (SIHD)</u></p> <ul style="list-style-type: none"> <li>• In adults with SIHD and hypertension, a BP target <math>&lt; 130/80</math> is recommended.</li> <li>• Adults with SIHD and hypertension (BP <math>\geq 130/80</math> mmHg) should be treated with medications [e.g., guideline-directed medical therapy (GDMT) beta-blockers, ACE inhibitors, or ARBs] for compelling indications [e.g., previous myocardial infarction (MI), stable angina] as first-line therapy, with the addition of other drugs (e.g., dihydropyridine CCBs, thiazide diuretics, and/or mineralocorticoid receptor antagonists) as needed to further control hypertension.</li> <li>• In adults with SIHD with angina and persistent uncontrolled hypertension, the addition of dihydropyridine CCBs to GDMT beta-blockers is recommended.</li> <li>• In adults who have had a MI or acute coronary syndrome, it is reasonable to continue GDMT beta-blockers beyond three years as long-term therapy for hypertension.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Beta-blockers and/or CCBs might be considered to control hypertension in patients with coronary artery disease (CAD) had an MI more than three years ago and have angina.</li> </ul> <p><u>Heart Failure</u></p> <ul style="list-style-type: none"> <li>• In adults with increased risk of HF, the optimal BP in those with hypertension should be &lt;130 mmHg.</li> <li>• Adults with HFrEF and hypertension should be prescribed GDMT titrated to attain a BP &lt;130/80 mmHg.</li> <li>• Non-dihydropyridine CCBs are not recommended in the treatment of hypertension in adults with HFrEF.</li> <li>• In adults with HFpEF who present with symptoms of volume overload, diuretics should be prescribed to control hypertension.</li> <li>• Adults with HFpEF and persistent hypertension after management of volume overload should be prescribed ACE inhibitors or ARBs and beta-blockers titrated to attain SBP &lt;130 mmHg.</li> </ul> <p><u>CKD</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and CKD should be treated to a BP goal &lt;130/80 mmHg.</li> <li>• In adults with hypertension and CKD [stage 3 or higher or stage 1 or 2 with albuminuria (<math>\geq 300</math> mg/d, or <math>\geq 300</math> mg/g albumin-to-creatinine ratio or the equivalent in the first morning void)], treatment with an ACE inhibitor is reasonable to slow kidney disease progression. Treatment with an ARB may be reasonable if an ACE inhibitor is not tolerated.</li> <li>• After kidney transplantation, it is reasonable to treat patients with hypertension to a BP goal &lt;130/80 mmHg and with a CCB on the basis of improved glomerular filtration rate (GFR) and kidney survival.</li> </ul> <p><u>Cerebrovascular Disease</u></p> <ul style="list-style-type: none"> <li>• In adults with intracerebral hemorrhage (ICH) who present with SBP &gt;220 mmHg, it is reasonable to use continuous intravenous (IV) drug infusion and close BP monitoring to lower levels. Immediate lowering of SBP to &lt;140 mmHg in adults with spontaneous ICH who present within six hours of the acute event and have an SBP between 150 mmHg and 220 mmHg is not of benefit to reduce death or severe disability and can be potentially harmful.</li> <li>• Adults with acute ischemic stroke and elevated BP who are eligible for treatment with IV tissue plasminogen activator (tPA) should have their BP slowly lowered to &lt;185/110 mmHg before thrombolytic therapy is initiated.</li> <li>• In adults with an acute ischemic stroke, BP should be &lt;185/110 mmHg before administration of IV tPA and should be maintained below 180/105 mmHg for at least the first 24 hours after initiation drug therapy.</li> <li>• Starting or restarting antihypertensive therapy during hospitalization in patients with BP &gt;140/90 mmHg who are neurologically stable is safe and reasonable to improve long-term BP control, unless contraindicated.</li> <li>• In patient with BP <math>\geq 220/120</math> mmHg who did not receive IV alteplase or endovascular treatment and have no comorbid conditions requiring acute antihypertensive treatment, the benefit of initiating or reinitiating treatment of hypertension within the first 48 to 72 hours is uncertain. It might be reasonable to lower BP by 15% during the first 24 hours after onset of stroke. In patients with BP &lt;220/120 mmHg with the same conditions, initiating or reinitiating treatment of hypertension within the first 48 to 72 hours after an acute ischemic stroke is not effective to prevent death or dependency.</li> <li>• Adults with previously treated stroke or transient ischemic attack should be restarted on antihypertensive treatment after the first few days of the index event</li> </ul>

Clinical Guideline	Recommendations
	<p>to reduce the risk of recurrent stroke and other vascular events. Treatment with a thiazide diuretic, ACE inhibitor, or ARB, or combination treatment consisting of a thiazide diuretic plus ACE inhibitor, is useful.</p> <ul style="list-style-type: none"> <li>• Adults not previously treated for hypertension who experienced a stroke or transient ischemic attack and have an established BP <math>\geq 140/90</math> mmHg should be prescribed antihypertensive treatment a few days after the index event to reduce the risk of recurrent stroke and other vascular event.</li> <li>• For adults who experience a stroke or transient ischemic attack, selection of specific drugs should be individualized on the basis of patient comorbidities and agent pharmacological class.</li> <li>• For adults who experience a stroke or transient ischemic attack, a BP goal <math>&lt;130/80</math> mmHg may be reasonable.</li> <li>• For adults with a lacunar stroke, a target SBP goal <math>&lt;130</math> mmHg may be reasonable.</li> <li>• In adults previously untreated for hypertension who experience an ischemic stroke or transient ischemic attack and have an SBP <math>&lt;140</math> mmHg and a DBP <math>&lt;90</math> mmHg, the usefulness of initiating antihypertensive treatment is not well established.</li> </ul> <p><u>Peripheral Artery Disease (PAD)</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and PAD should be treated similarly to patients with hypertension without PAD.</li> </ul> <p><u>Diabetes Mellitus (DM)</u></p> <ul style="list-style-type: none"> <li>• In adults with DM and hypertension, antihypertensive drug treatment should be initiated at a BP of <math>\geq 130/80</math> mmHg with a treatment goal <math>&lt;130/80</math> mmHg.</li> <li>• In adults with DM and hypertension, all first-line classes of antihypertensive agents (i.e., diuretics, ACE inhibitors, ARBs, and CCBs) are useful and effective.</li> <li>• In adults with DM and hypertension, ACE inhibitors or ARBs may be considered in the presence of albuminuria.</li> </ul> <p><u>Atrial Fibrillation, Valvular Heart Disease, and Aortic disease</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension can be useful for prevention of recurrence of AF.</li> <li>• In adults with asymptomatic aortic stenosis, hypertension should be treated with pharmacotherapy, starting at a low dose and gradually titrating upward as needed.</li> <li>• In patients with chronic aortic insufficiency, treatment of systolic hypertension with agents that do not slow the heart rate (i.e., avoid beta-blockers) is reasonable.</li> <li>• Beta-blockers are recommended as the preferred antihypertensive agents in patients with hypertension and thoracic aortic disease.</li> </ul> <p><u>Racial and Ethnic Differences in Treatment</u></p> <ul style="list-style-type: none"> <li>• In black adults with hypertension but without HF or CKD, including those with DM, initial antihypertensive treatment should include a thiazide-type diuretic or CCB. Two or more antihypertensive medications are recommended to achieve a BP target <math>&lt;130/80</math> mmHg in most adults with hypertension, especially in black adults with hypertension.</li> </ul> <p><u>Pregnancy</u></p> <ul style="list-style-type: none"> <li>• Women with hypertension who become pregnant, or are planning to become pregnant, should be transitioned to methyldopa, nifedipine, and/or labetalol during pregnancy.</li> <li>• Women with hypertension who become pregnant should not be treated with ACE inhibitors, ARBs, or direct renin inhibitors.</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Older Persons</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension with an SBP treatment goal &lt;130 mmHg is recommended for noninstitutionalized ambulatory community-dwelling adults (≥65 years of age) with an average SBP of ≥130 mmHg.</li> <li>• For older adults (≥65 years of age) with hypertension and a higher burden of comorbidity and limited life expectancy, clinical judgment, patient preference, and a team-based approach to assess risk/benefit is reasonable for decisions regarding intensity of BP lowering and choice of antihypertensive drugs.</li> </ul> <p><u>Hypertensive Crises</u></p> <ul style="list-style-type: none"> <li>• In adults with a hypertensive emergency, admission to an intensive care unit is recommended for continuous monitoring of BP and target organ damage and for parenteral administration of an appropriate agent.</li> <li>• For adults with a compelling condition (i.e., aortic dissection, severe pre-eclampsia or eclampsia, or pheochromocytoma crisis), SBP should be reduced to &lt;140 mmHg during the first hour and to &lt;120 mmHg in aortic dissection.</li> <li>• For adults without a compelling condition, SBP should be reduced by no more than 25% within the first hours; then, if stable, to 160/100 mmHg within the next two to six hours; and then cautiously to normal during the following 24 to 48 hours.</li> </ul> <p><u>Cognitive Decline and Dementia</u></p> <ul style="list-style-type: none"> <li>• In adults with hypertension, BP lowering is reasonable to prevent cognitive decline and dementia.</li> </ul> <p><u>Patients Undergoing Surgical Procedures</u></p> <ul style="list-style-type: none"> <li>• In patients with hypertension undergoing major surgery who have been on beta-blockers chronically, beta-blockers should be continued.</li> <li>• In patients with hypertension undergoing planned elective major surgery, it is reasonable to continue medical therapy for hypertension until surgery.</li> <li>• In patients with hypertension undergoing major surgery, discontinuation of ACE inhibitors or ARBs perioperatively may be considered.</li> <li>• In patients with planned elective major surgery and SBP ≥180 mmHg or DBP ≥110 mmHg, deferring surgery may be considered.</li> <li>• For patients undergoing surgery, abrupt pre-operative discontinuation of beta-blockers or clonidine is potentially harmful.</li> <li>• Beta-blockers should not be started on the day of surgery in beta-blocker-naïve patients.</li> <li>• Patients with intraoperative hypertension should be managed with IV medications until such time as oral medications can be resumed.</li> </ul>
<p>American Diabetes Association: <b>Standards of Medical Care in Diabetes (2022)</b><sup>28</sup></p>	<p><u>Hypertension/blood pressure control</u></p> <ul style="list-style-type: none"> <li>• Blood pressure should be measured at every routine visit. When possible, patients found to have elevated blood pressure (≥140/90) should have blood pressure confirmed using multiple readings, including measurements on a separate day, to diagnose hypertension. Patients with blood pressure ≥180/110 and cardiovascular disease could be diagnosed with hypertension at a single visit.</li> <li>• All hypertensive patients with diabetes should monitor their blood pressure at home.</li> <li>• For patients with diabetes and hypertension, with diabetes and hypertension, blood pressure targets should be individualized through a shared decision-making process that addresses cardiovascular risk, potential adverse effects of antihypertensive medications, and patient preferences.</li> <li>• For individuals with diabetes and hypertension at higher cardiovascular risk (existing atherosclerotic cardiovascular disease [ASCVD] or 10-year ASCVD risk ≥15%), a blood pressure target of &lt;130/80 mmHg may be appropriate, if it</li> </ul>

Clinical Guideline	Recommendations
	<p>can be safely attained.</p> <ul style="list-style-type: none"> <li>• For individuals with diabetes and hypertension at lower risk for cardiovascular disease (10-year atherosclerotic cardiovascular disease risk &lt;15%), treat to blood pressure target of &lt;140/90.</li> <li>• In pregnant patients with diabetes and preexisting hypertension, a blood pressure target of 110 to 135/85 is suggested in the interest of reducing the risk for accelerated maternal hypertension and minimizing impaired fetal growth.</li> <li>• For patients with blood pressure &gt;120/80, lifestyle intervention consists of weight loss when indicated, a Dietary Approaches to Stop Hypertension (DASH)-style eating pattern including reducing sodium and increasing potassium intake, moderation of alcohol intake, and increased physical activity.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq</math>140/90 mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of pharmacologic therapy to achieve blood pressure goals.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq</math>160/100 mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of two drugs or a single pill combination of drugs demonstrated to reduce cardiovascular events in patients with diabetes.</li> <li>• Treatment for hypertension should include drug classes demonstrated to reduce cardiovascular events in patients with diabetes (ACE inhibitors, angiotensin receptor blockers, thiazide-like diuretics, or dihydropyridine calcium channel blockers). ACE inhibitors or angiotensin receptor blockers are recommended first-line therapy for hypertension in people with diabetes and coronary artery disease.</li> <li>• Multiple-drug therapy is generally required to achieve blood pressure targets (but not a combination of ACE inhibitors and angiotensin receptor blockers).</li> <li>• An ACE inhibitor or angiotensin receptor blocker, at the maximum tolerated dose indicated for blood pressure treatment, is the recommended first-line treatment for hypertension in patients with diabetes and urinary albumin-to-creatinine ratio <math>\geq</math>300 mg/g creatinine or 30 to 299 mg/g creatinine. If one class is not tolerated, the other should be substituted.</li> <li>• For patients treated with an ACE inhibitor, angiotensin receptor blocker, or diuretic, serum creatinine/estimated glomerular filtration rate and serum potassium levels should be monitored at least annually.</li> <li>• Patients with hypertension who are not meeting blood pressure targets on three classes of antihypertensive medications (including a diuretic) should be considered for mineralocorticoid receptor antagonist therapy.</li> </ul> <p><u>Chronic kidney disease</u></p> <ul style="list-style-type: none"> <li>• At least once a year, assess urinary albumin (e.g., spot urinary albumin-to-creatinine ratio) and estimated glomerular filtration rate in patients with type 1 diabetes with duration of five or more years and in all patients with type 2 diabetes.</li> <li>• Patients with diabetes and urinary albumin <math>\geq</math>300 mg/g creatinine and/ or an estimated glomerular filtration rate 30 to 60 mL/min/1.73 m<sup>2</sup> should be monitored twice annually to guide therapy.</li> <li>• Optimize glucose control to reduce the risk or slow the progression of chronic kidney disease (CKD).</li> <li>• For patients with type 2 diabetes and diabetic kidney disease, use of a sodium-glucose cotransporter 2 inhibitor in patients with an estimated glomerular filtration rate <math>\geq</math>25 mL/min/1.73 m<sup>2</sup> and urinary albumin <math>\geq</math>300 mg/g creatinine is recommended to reduce CKD progression and cardiovascular events.</li> <li>• In patients with type 2 diabetes and CKD, consider use of sodium-glucose cotransporter 2 inhibitors additionally for cardiovascular risk reduction when estimated glomerular filtration rate and urinary albumin creatinine are <math>\geq</math>25</li> </ul>

Clinical Guideline	Recommendations
	<p>mL/min/1.73 m<sup>2</sup> or ≥300 mg/g, respectively.</p> <ul style="list-style-type: none"> <li>• In patients with CKD who are at increased risk for cardiovascular events or CKD progression and are unable to use a sodium–glucose cotransporter 2 inhibitor, a nonsteroidal mineralocorticoid receptor antagonist (finerenone) is recommended to reduce CKD progression and cardiovascular events.</li> <li>• Optimize blood pressure control and reduce blood pressure variability to reduce the risk or slow the progression of CKD.</li> <li>• Do not discontinue renin-angiotensin system blockade for minor increases in serum creatinine (≤30%) in the absence of volume depletion.</li> <li>• For people with nondialysis-dependent stage 3 or higher CKD, dietary protein intake should be a maximum of 0.8 g/kg body weight per day (the recommended daily allowance). For patients on dialysis, higher levels of dietary protein intake should be considered, since malnutrition is a major problem in some dialysis patients.</li> <li>• In nonpregnant patients with diabetes and hypertension, either an ACE inhibitor or an angiotensin receptor blocker is recommended for those with modestly elevated urinary albumin–to–creatinine ratio (30 to 299 mg/g creatinine) and is strongly recommended for those with urinary albumin–to–creatinine ratio ≥300 mg/g creatinine and/or estimated glomerular filtration rate &lt;60 mL/min/1.73 m<sup>2</sup>.</li> <li>• Periodically monitor serum creatinine and potassium levels for the development of increased creatinine or changes in potassium when ACE inhibitors, angiotensin receptor blockers, or diuretics are used.</li> <li>• An ACE inhibitor or an angiotensin receptor blocker is not recommended for the primary prevention of CKD in patients with diabetes who have normal blood pressure, normal urinary albumin–to–creatinine ratio (&lt;30 mg/g creatinine), and normal estimated glomerular filtration rate.</li> <li>• Patients should be referred for evaluation by a nephrologist if they have an estimated glomerular filtration rate &lt;30 mL/min/1.73 m<sup>2</sup>.</li> <li>• Promptly refer to a nephrologist for uncertainty about the etiology of kidney disease, difficult management issues, and rapidly progressing kidney disease.</li> </ul>
<p>American Association for the Study of Liver Diseases: <b>Diagnosis, Evaluation, and Management of Ascites, Spontaneous Bacterial Peritonitis and Hepatorenal Syndrome: 2021 Practice Guidance (2021)</b><sup>29</sup></p>	<p><b>Treatment of ascites</b></p> <ul style="list-style-type: none"> <li>• Moderate sodium restriction (2 g or 90 mmol/day) and diuretics (spironolactone with or without furosemide) are the first-line treatment in patients with cirrhosis and grade 2 ascites.</li> <li>• After ascites is adequately mobilized, attempts should be made to taper the diuretics to the lowest dose necessary to maintain minimal or no ascites to prevent the development of adverse effects.</li> <li>• Fluid restriction is not necessary unless serum sodium is &lt;125 mmol/L.</li> <li>• In patients receiving diuretics, body weight and serum creatinine and sodium should be regularly monitored to assess response and to detect the development of adverse effects.</li> <li>• Human albumin solution (20 to 40 g/week) or baclofen administration (10 mg/day, with a weekly increase of 10 mg/day, up to 30 mg/day) can be considered in cases of severe muscle cramps.</li> <li>• Large-volume paracentesis is the first-line treatment of grade 3 ascites. After paracentesis, sodium restriction and diuretics should be started.</li> <li>• Referral for liver transplant evaluation should be considered in patients with grade 2 or 3 ascites.</li> <li>• Nonsteroidal anti-inflammatory drugs, angiotensin-converting enzyme inhibitors, and angiotensin receptor blockers should be avoided in patients with cirrhosis and ascites.</li> <li>• Aminoglycosides should be avoided whenever possible in the treatment of bacterial infections.</li> <li>• For patients with cirrhosis and diuretic-responsive ascites, controversial data</li> </ul>

Clinical Guideline	Recommendations
	suggest potential benefits of long-term infusion of human albumin solution. At present, no recommendation can be made for its use in routine clinical practice.
Endocrine Society: <b>The Management of Primary Aldosteronism: Case Detection, Diagnosis, and Treatment (2016)</b> <sup>30</sup>	<ul style="list-style-type: none"> <li>• Unilateral laparoscopic adrenalectomy is recommended for patients with documented unilateral primary aldosteronism (i.e., aldosterone-producing adenoma [APA] or unilateral adrenal hyperplasia [UAH]). If a patient is unable or unwilling to undergo surgery, medical treatment including a mineralocorticoid receptor (MR) antagonist is recommended. If an aldosterone to renin ratio (ARR)-positive patient is unwilling or unable to undergo further investigations, medical treatment including an MR antagonist is recommended.</li> <li>• In patients with primary aldosteronism due to bilateral adrenal disease, medical treatment with an MR antagonist is recommended; spironolactone is suggested as the primary agent, with eplerenone as an alternative</li> <li>• In patients with glucocorticoid remediable aldosteronism (GRA), administering the lowest dose of glucocorticoid to lower adrenocorticotropic hormone (ACTH) and thus normalize BP and potassium levels is recommended as the first-line treatment. In addition, if BP fails to normalize with glucocorticoid alone, an MR antagonist may be added. For children, the glucocorticoid dosage should be adjusted for age and body weight, and BP targets should be determined from age- and gender-specific published normative data.</li> </ul>

\*Agent not available in the United States.

### III. Indications

The Food and Drug Administration (FDA)-approved indications for the mineralocorticoid (aldosterone) receptor antagonists are noted in Table 3. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 3. FDA-Approved Indications for the Mineralocorticoid (Aldosterone) Receptor Antagonists<sup>1-7</sup>**

Indication(s)	Single Entity Agents			Combination Products
	Eplerenone	Finerenone	Spironolactone	Spironolactone and HCTZ
<b>Edematous Conditions</b>				
Maintenance therapy together with bed rest and the restriction of fluid and sodium in patients with cirrhosis of the liver accompanied by edema and/or ascites			✓	✓
Management of edema and sodium retention when the patient is only partially responsive to, or is intolerant of, other therapeutic measures			✓	✓
Nephrotic patients when treatment of the underlying disease, restriction of fluid and sodium intake, and the use of other diuretics do not provide an adequate response			✓	✓
Patients with congestive heart failure taking digitalis when other therapies are considered inappropriate			✓	✓
<b>Heart Failure</b>				
Increase survival and reduce the need for hospitalization for heart failure when used in addition to standard therapy in patients with severe heart failure (New York Heart			✓	

Indication(s)	Single Entity Agents			Combination Products
	Eplerenone	Finerenone	Spirolactone	Spirolactone and HCTZ
Association functional class III-IV)				
<b>Hypertension</b>				
Essential hypertension				✓ *
Hypertension	✓ †		✓ ‡	
<b>Hypokalemia</b>				
Prophylaxis of hypokalemia in patients taking digitalis when other measures are considered inadequate or inappropriate			✓	
Treatment of a diuretic-induced hypokalemia in patients with congestive heart failure when other measures are considered inappropriate				✓
Treatment of diuretic-induced hypokalemia in patients with hypertension when other measures are considered inappropriate				✓
Treatment of patients with hypokalemia when other measures are considered inappropriate or inadequate			✓	
<b>Myocardial Infarction</b>				
To improve survival of stable patients with left ventricular systolic dysfunction (ejection fraction ≤40%) and clinical evidence of congestive heart failure after an acute myocardial infarction	✓			
<b>Primary Hyperaldosteronism</b>				
Establish the diagnosis of primary hyperaldosteronism by therapeutic trial			✓	
Short-term preoperative treatment of patients with primary hyperaldosteronism			✓	
Long-term maintenance therapy for patients with discrete aldosterone-producing adrenal adenomas who are judged to be poor operative risks or who decline surgery			✓	
Long-term maintenance therapy for patients with bilateral micro or macronodular adrenal hyperplasia (idiopathic hyperaldosteronism)			✓	
<b>Diabetic Kidney Disease</b>				
To reduce the risk of sustained eGFR decline, end stage kidney disease, cardiovascular death, non-fatal myocardial infarction, and hospitalization for heart failure in adult patients with chronic kidney disease associated with type 2 diabetes		✓		

\*In patients in whom other measures are considered inadequate or inappropriate.

†Alone or in combination with other antihypertensive agents.

‡Usually in combination with other drugs, in patients who cannot be treated adequately with other agents or for whom other agents are considered inappropriate.

eGFR=estimated glomerular filtration rate, HCTZ=hydrochlorothiazide

#### IV. Pharmacokinetics

The pharmacokinetic parameters of the mineralocorticoid (aldosterone) receptor antagonists are listed in Table 4.

**Table 4. Pharmacokinetic Parameters of the Mineralocorticoid (Aldosterone) Receptor Antagonists<sup>2</sup>**

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life (hours)
<b>Single Entity Agents</b>					
Eplerenone	69	50	Liver, extensive (% not reported)	Renal (67) Feces (32)	3 to 6
Finerenone	44	92	Liver (% not reported)	Renal (80) Feces (20)	2 to 3
Spironolactone	73	90	Liver (% not reported) Renal (% not reported)	Renal (47 to 57) Feces (35 to 41)	1.3 to 1.4
<b>Combination Products</b>					
Spironolactone and HCTZ	73/ 60 to 80	90/40	Liver (% not reported) Renal (% not reported)	Feces (35 to 41) Renal (47 to 57)/ Renal (50 to 70)	1.3 to 1.4/ 4 to 5

HCTZ=hydrochlorothiazide

#### V. Drug Interactions

Major drug interactions with the mineralocorticoid (aldosterone) receptor antagonists are listed in Table 5.

**Table 5. Major Drug Interactions with the Mineralocorticoid (Aldosterone) Receptor Antagonists<sup>2</sup>**

Generic Name(s)	Interaction	Mechanism
Mineralocorticoid receptor antagonists (eplerenone, spironolactone)	ACE inhibitors	Serious hyperkalemia, possibly with cardiac arrhythmias or arrest, may occur with the combination of aldosterone blockers and ACE inhibitors. Potassium sparing effects are additive when combining ACE inhibitors with aldosterone blockers. Aldosterone acts in the renal cortical collecting ducts by inducing synthesis of proteins that constitute the Na <sup>+</sup> , K <sup>+</sup> -ATPase pump. The pump acts to reabsorb sodium and water in exchange for potassium, which is then eliminated in the urine. Aldosterone antagonism can cause hyperkalemia.
Mineralocorticoid receptor antagonists (eplerenone)	Amiloride	Aldosterone blockers and amiloride may exert additive pharmacologic effects. Hyperkalemia with the potential for cardiac arrhythmias may result. Aldosterone blockers and amiloride may cause additive adverse effects when co-administered.
Mineralocorticoid receptor antagonists (eplerenone, spironolactone)	Potassium Preparations	Potassium preparations will increase serum potassium concentrations. This may increase the potential for clinically important hyperkalemia, especially when used concomitantly with aldosterone blockers.
Mineralocorticoid receptor antagonists (eplerenone, spironolactone)	Triamterene	Eplerenone and triamterene may exert additive pharmacologic effects. Hyperkalemia with the potential for cardiac arrhythmias may result.
Mineralocorticoid receptor antagonists (eplerenone)	HIV Protease Inhibitors	Inhibition of CYP3A4 isoenzymes by HIV protease inhibitors may decrease the metabolic elimination of aldosterone blockers. HIV protease inhibitors may increase plasma concentrations and pharmacologic or toxic effects of aldosterone blockers.
Mineralocorticoid receptor antagonists	Imidazoles	Certain azole antifungal agents may decrease the elimination of eplerenone by inhibiting its hepatic metabolism via

Generic Name(s)	Interaction	Mechanism
(eplerenone)		CYP3A4 isoenzyme resulting in increased concentration and consequently increased pharmacologic and toxic (hyperkalemia associated with potentially fatal arrhythmias) effects of eplerenone.
Mineralocorticoid receptor antagonists (eplerenone)	Macrolides	Macrolides may decrease the elimination of eplerenone by inhibiting its hepatic metabolism via CYP3A4 isoenzyme resulting in increased concentration and consequently increased pharmacologic and toxic (hyperkalemia associated with potentially fatal arrhythmias) effects of eplerenone.
Mineralocorticoid receptor antagonists (eplerenone)	Nefazodone	Nefazodone may decrease the elimination of eplerenone by inhibiting its hepatic metabolism via CYP3A4 isoenzyme resulting in increased concentration and consequently increased pharmacologic and toxic (hyperkalemia associated with potentially fatal arrhythmias) effects of eplerenone. Coadministration of eplerenone with nefazodone is contraindicated.
Mineralocorticoid receptor antagonists (eplerenone)	Spironolactone	Eplerenone and spironolactone may exert additive pharmacologic effects. Hyperkalemia with the potential for cardiac arrhythmias may result.
Mineralocorticoid receptor antagonists (eplerenone)	Verapamil	Inhibition of CYP3A4 isoenzymes by verapamil may decrease the metabolic elimination of eplerenone. Verapamil may increase plasma concentrations and pharmacologic or toxic effects of eplerenone.
Mineralocorticoid receptor antagonists (spironolactone)	Angiotensin II Receptor Antagonists	Decreased aldosterone activity by angiotensin II receptor antagonists may function synergistically with potassium conservation by spironolactone to produce substantial hyperkalemia. The risk of hyperkalemia may be increased when spironolactone is co-administered with angiotensin II receptor antagonists.
Mineralocorticoid receptor antagonists (spironolactone)	Eplerenone	Concurrent use of eplerenone and spironolactone may result in increased risk of hyperkalemia.
Mineralocorticoid receptor antagonists (spironolactone)	Digoxin	Concurrent use of digoxin and spironolactone may result in increased digoxin exposure.
Thiazide diuretics (HCTZ)	Dofetilide	Thiazide diuretics may induce hypokalemia which may increase the risk of torsades de pointes. The coadministration of dofetilide with a thiazide diuretic is contraindicated.
Mineralocorticoid receptor antagonists (spironolactone)	Lithium	Concurrent use of lithium and spironolactone may result in increased lithium concentrations and lithium toxicity (weakness, tremor, excessive thirst, confusion).
Mineralocorticoid receptor antagonists (finerenone)	Strong CYP3A4 inhibitors	Concurrent use of finerenone and strong CYP3A4 inhibitors may result in increased finerenone exposure.
Mineralocorticoid receptor antagonists (finerenone)	Moderate or weak CYP3A4 inhibitors	Concurrent use of finerenone and moderate or weak CYP3A4 inhibitors may result in increased finerenone exposure.
Mineralocorticoid receptor antagonists (finerenone)	Strong or moderate CYP3A4 inducers	Concurrent use of finerenone and strong or moderate CYP3A4 inducers may result in decreased finerenone exposure.
Thiazide diuretics (HCTZ)	Diazoxide	The combination of diazoxide with a thiazide diuretic may lead to hyperglycemia through an unknown mechanism; therefore the combination should be avoided. When used together, blood and urine glucose levels should be frequently monitored, and dosage reductions may be required.
Thiazide diuretics	Digitalis glycosides	Thiazide diuretics may induce electrolyte disturbances which

Generic Name(s)	Interaction	Mechanism
(HCTZ)		may predispose patients to digitalis-induced arrhythmias. Measure plasma levels of potassium and magnesium, supplement low levels, and use dietary sodium restriction or potassium-sparing diuretics to prevent further losses.

ACE inhibitors=angiotensin converting enzyme inhibitors, CYP=cytochrome P450 isoenzyme, HCTZ=hydrochlorothiazide, HIV=human immunodeficiency virus

## VI. Adverse Drug Events

The most common adverse drug events reported with the mineralocorticoid (aldosterone) receptor antagonists are listed in Table 6.

**Table 6. Adverse Drug Events (%) Reported with the Mineralocorticoid (Aldosterone) Receptor Antagonists<sup>1-7</sup>**

Adverse Events	Single Entity Agents			Combination Products
	Eplerenone	Finerenone	Spirolactone	Spirolactone and HCTZ

## VII. Dosing and Administration

The usual dosing regimens for the mineralocorticoid (aldosterone) receptor antagonists are listed in Table 7.

**Table 7. Usual Dosing Regimens for the Mineralocorticoid (Aldosterone) Receptor Antagonists<sup>1-7</sup>**

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability	
<b>Single Entity Agents</b>				
Eplerenone	<p><u>Heart Failure:</u> Tablet: initial, 25 mg once daily for four weeks; maintenance, 50 mg once daily</p> <p><u>Hypertension:</u> Tablet: initial, 50 mg once daily; maximum, 50 mg twice daily</p>	Safety and efficacy in children have not been established.	Tablet: 25 mg 50 mg	
Finerenone	<p><u>Chronic kidney disease associated with type 2 diabetes:</u> Tablet: initial, 10 to 20 mg once daily based on estimated glomerular filtration rate; target dose is 20 mg once daily</p>	Safety and efficacy in children have not been established.	Tablet: 10 mg 20 mg	
Spironolactone	<p><u>Edema (congestive heart failure, hepatic cirrhosis, nephrotic syndrome):</u> Tablet: initial, 100 mg once daily in a single or divided dose(s); maintenance, 25 to 200 mg once daily</p> <p><u>Edema caused by cirrhosis:</u> Suspension: initiate therapy in a hospital setting and titrate slowly; initial, 75 mg (15 mL) per day in single or divided doses; in patients requiring titration above 100 mg, use another formulation</p> <p><u>Heart failure (Severe NYHA function class III to IV)</u> Suspension: initial, 20 mg (4 mL) once daily; maintenance, 37.5 mg (7.5 mL) once daily</p> <p>Tablet: initial, 25 mg once daily; maintenance, 25 mg every other day to 50 mg once daily</p> <p><u>Hypertension</u> Suspension: 20 mg (4 mL) to 75 mg (15 mL) per day in single or divided doses</p> <p>Tablet: initial, 50 to 100 mg once daily in a single or divided dose(s); maintenance, 25 to 200 mg once daily;</p>	Safety and efficacy in children have not been established.	Suspension: 25 mg/5 mL	Tablet: 25 mg 50 mg 100 mg

Mineralocorticoid (Aldosterone) Receptor Antagonists  
AHFS Class 243220

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
	<p>maximum, 400 mg/day</p> <p><u>Hypokalemia:</u> Tablet: 25 to 100 mg once daily</p> <p><u>Primary hyperaldosteronism (diagnosis):</u> Tablet (long test): 400 mg/day for three to four weeks</p> <p>Tablet (short test): 400 mg daily for four days</p> <p><u>Primary hyperaldosteronism (short-term preoperative therapy):</u> Tablet: 100 to 400 mg/day prior to surgery</p> <p><u>Primary hyperaldosteronism (long-term maintenance therapy):</u> Tablet: initial, 100 to 400 mg/day; maximum, 400 mg/day</p>		
<b>Combination Products</b>			
<p>Spironolactone and HCTZ</p>	<p><u>Edema (congestive heart failure, hepatic cirrhosis, nephrotic syndrome):</u> Tablet: maintenance, 100-100 mg/day in a single or divided dose(s); maintenance, 25-25 to 200-200 mg/day</p> <p><u>Hypertension:</u> Tablet: maintenance, 50-50 to 100-100 mg/day in a single or divided dose(s)</p>	<p>Safety and efficacy in children have not been established.</p>	<p>Tablet: 25-25 mg 50-50 mg</p>

HCTZ=hydrochlorothiazide

**VIII. Effectiveness**

Clinical studies evaluating the safety and efficacy of the mineralocorticoid (aldosterone) receptor antagonists are summarized in Table 8.

**Table 8. Comparative Clinical Trials with the Mineralocorticoid (Aldosterone) Receptor Antagonists**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<b>Diabetes/Diabetic Nephropathy/Renal Disease</b>				
<p>Bianchi et al.<sup>31</sup> (2006)</p> <p>Spirolactone 25 mg/day</p> <p>vs</p> <p>placebo</p> <p>All patients were receiving conventional therapy (ACE inhibitor and/or ARB).</p>	<p>OL, PC, PRO, RCT</p> <p>Adult patients with chronic kidney disease</p>	<p>N=165</p> <p>1 year</p>	<p>Primary: Change in proteinuria, eGFR, blood pressure, and serum potassium</p> <p>Secondary: Not reported</p>	<p>Primary: While there was a significant reduction in proteinuria from baseline among spironolactone-treated patients (P&lt;0.001), there was no difference in placebo-treated patients (P&gt;0.05).</p> <p>At one year, there was no significant difference between spironolactone- and placebo-treated patients in eGFR (P value not reported). However, spironolactone-treated patients exhibited a lower monthly rate of decrease in eGFR from baseline compared to conventional therapy-treated patients (P&lt;0.01). Patients whose baseline eGFR was &lt;60 mL/min experienced a greater decline in eGFR compared to patients with baseline eGFR &gt;60 mL/min (P&lt;0.01).</p> <p>At one year of therapy, spironolactone-treated patients experienced a reduction in blood pressure from baseline (P&lt;0.05). In contrast, placebo-treated patients did not exhibit blood pressure reduction from baseline (P value not reported).</p> <p>While there was a significant increase in serum potassium from baseline among spironolactone-treated patients (P&lt;0.001), there was no difference in placebo-treated (P&gt;0.05).</p> <p>Secondary: Not reported</p>
<p>Bianchi et al.<sup>32</sup> (2010)</p> <p>Spirolactone 25 mg, ramipril 10 mg, irbesartan 300 mg, and atorvastatin 10</p>	<p>RCT, OL</p> <p>Patients with a clinical diagnosis of idiopathic chronic glomerulonephritis and urine</p>	<p>N=128</p> <p>36 months</p>	<p>Primary: Changes over time in proteinuria and eGFR</p> <p>Secondary: Adverse events,</p>	<p>Primary: SBP decreased more in the intensive-therapy group (from 156.6 to 113.5 mm Hg) than in the conventional therapy group (from 155.7 to 122.7 mm Hg; P&lt;0.01).</p> <p>Urine protein excretion decreased from 2.65 to 0.45 g/g creatinine with intensive therapy (P&lt;0.001). With conventional therapy, urine protein</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>mg QD (intensive therapy)</p> <p>vs</p> <p>ramipril 10 mg and atorvastatin 10 mg QD (conventional therapy)</p> <p>The addition of diuretics, calcium antagonists, <math>\beta</math>-blockers or <math>\alpha</math>1-receptor antagonists were added to achieve blood pressure &lt;130/80 mm Hg</p>	<p>protein-creatinine ratio &gt;1 g/g</p>		<p>drop outs</p>	<p>excretion decreased from 2.60 to 1.23 g/g creatinine (P&lt;0.001).</p> <p>With intensive therapy, eGFR did not significantly change over time (64.6 vs 62.9 mL/min/1.73 m<sup>2</sup>). With conventional therapy, eGFR decreased from 62.5 to 55.8 mL/min/1.73 m<sup>2</sup> (P&lt;0.01).</p> <p>Secondary: In the conventional therapy group, eight patients discontinued the study due to hyperkalemia, cough, and rapid deterioration in kidney function. In the intensive therapy group, 15 dropped out due to hyperkalemia, cough, and hypotension. Nine patients in the intensive therapy group developed gynecomastia. Twelve patients on conventional and 31 on intensive therapy had to interrupt the study temporarily because of low blood pressure. No patient developed an increase in creatine kinase, alanine aminotransferase, and alkaline phosphatase levels during the study.</p>
<p>Ogawa et al.<sup>33</sup> (2006)</p> <p>Spirolactone 25 mg/day plus imidapril* 5 mg/day</p> <p>vs</p> <p>furosemide 20 mg/day plus imidapril* 5 mg/day</p> <p>All patients were pre-treated with imidapril* for 1 year prior to trial onset.</p>	<p>PRO, RCT</p> <p>Adult patients with HTN and type 2 diabetes, with a urine albumin/creatinine ratio &gt;30 mg/g creatinine, and plasma BNP levels &gt;100 pg/mL (suggestive of mild heart failure)</p>	<p>N=30</p> <p>24 months</p>	<p>Primary: Change in BNP, urine albumin/creatinine ratio and blood pressure</p> <p>Secondary: Not reported</p>	<p>Primary: At 12 months, spironolactone-treated patients exhibited a significant reduction in BNP level from baseline compared to furosemide-treated patients (P&lt;0.05).</p> <p>At 12 months, spironolactone-treated patients exhibited a significant reduction in urine albumin/creatinine ratio from baseline compared to furosemide-treated patients (P&lt;0.05).</p> <p>Both treatments exhibited similar reductions in blood pressure from baseline (P value not reported).</p> <p>No adverse events were reported in this trial.</p> <p>Secondary: Not reported</p>

Girerd et al. <sup>52</sup> (2015) EMPHASIS-HF  Eplerenone 25 mg QD for 4 weeks, followed by 50 mg QD  vs placebo	Subgroup analysis of EMPHASIS-HF  Patients included in the EMPHASIS-HF trial analyzed according to whether the treatment was initiated <42 or 42+ days after qualifying CV hospitalization	N=2,338  21 months (median follow up)	Primary: Composite of cardiovascular mortality or hospitalization for HF  Secondary: Adverse effects	Primary: The relative rate reductions in CV death/hospitalization for HF, hospitalization for HF, and all-cause mortality were similar (P for interaction=0.65, 0.44, and 0.40, respectively) whether the treatment was initiated <42 or 42+ days after qualifying CV hospitalization. Absolute rate reductions were -5.61 (95% CI, -8.67 to -2.55) events per 100 patient-years in the <42 days group and -3.58 (CI, -6.37 to -0.79) in the 42+ days group. Regardless of the event considered, cumulative incidences of events in patients treated with eplerenone were lower than the rates observed in patients allocated to placebo in both the <42 and the 42+ days groups.  Secondary: The adverse effects of eplerenone were also unaffected by the time from the qualifying CV hospitalization.
Pitt et al. <sup>53</sup> (1999) RALES  Spironolactone 25 mg/day; in the absence of hyperkalemia, the dose could be increased to 50 mg/day after 8 weeks; if hyperkalemia developed the dose could be decreased to 25 mg every other day	DB, MC, RCT  Patients with NYHA class 4 heart failure within 6 months and with NYHA class 3 to 4 at study onset, diagnosed with CHF $\geq$ 6 weeks, treated with an ACE inhibitor and a loop diuretic, with a LVEF $\leq$ 35%	N=1,663  24 months (mean follow-up)	Primary: Death from any cause  Secondary: Death from cardiac causes, hospitalization for cardiac causes, combined incidence of death or hospitalization for cardiac causes, combined end point of death or hospitalizations from any cause,	Primary: There were 386 and 284 deaths from any cause in placebo- and spironolactone-treated patients (RR, 0.70; 95% CI, 0.60 to 0.82; P<0.001).  Secondary: There were 314 and 226 deaths in placebo- and spironolactone-treated patients that were attributed to cardiac causes (RR, 0.69; 95% CI, 0.58 to 0.82; P<0.001).  There were 753 and 515 hospitalizations for cardiac causes in placebo- and spironolactone-treated patients (RR, 0.70; 95% CI, 0.59 to 0.82; P<0.001).  The combined end point of death from cardiac causes or hospitalizations from cardiac causes showed a 32% reduction in risk among spironolactone-treated patients compared to placebo-treated patients (RR, 0.68; 95% CI, 0.59 to 0.78; P<0.001).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs placebo			combined end point of death from any cause or hospitalizations from cardiac causes, change in the NYHA class, adverse events	<p>The combined end point of death or hospitalizations from any cause showed a 23% reduction in risk among spironolactone-treated patients compared to placebo-treated patients (RR, 0.77; 95% CI, 0.68 to 0.86; P&lt;0.001).</p> <p>The combined end point of death from any cause or hospitalizations from cardiac causes showed a 32% reduction in risk among spironolactone-treated patients as compared to placebo-treated patients (RR, 0.68; 95% CI, 0.60 to 0.77; P&lt;0.001).</p> <p>A significantly greater percentage of spironolactone-treated patients experienced improvement in the NYHA class compared to placebo-treated patients (41 vs 33%; P&lt;0.001).</p> <p>Gynecomastia or breast pain was reported in 10 and 1% of spironolactone- and placebo-treated men (P&lt;0.001). The incidence of hyperkalemia was minimal with both treatments.</p>
Vardeny et al. <sup>54</sup> (2012) RALES  Spironolactone 25 or 50 mg/day  vs placebo	Post-hoc analysis  Patients with NYHA class III or IV heart failure with an ejection fraction <35%	N=1,658  24 months (mean follow-up)	Primary: Death from any cause  Secondary: Death from cardiac causes, hospitalization for cardiac causes, combined incidence of death or hospitalization for cardiac causes, combined end point of death or hospitalizations from any cause, combined end point of death from	<p>Primary: Patients with reduced baseline eGFR exhibited similar RR reductions in all cause mortality and the composite of death or hospital stays for heart failure compared to patients with a baseline eGFR &gt;60 mL/min/1.73 m<sup>2</sup>, and a greater absolute risk reduction compared to patients with a higher baseline eGFR (10.3 vs 6.4%).</p> <p>Worsening renal failure (17 vs 7%; P&lt;0.001) was associated with an increased adjusted risk of death with placebo (HR, 1.9; 95% CI, 1.3 to 2.6) but not with spironolactone (HR, 1.1; 95% CI, 0.79 to 1.5; P=0.009).</p> <p>The risk of hyperkalemia and renal failure was higher in patients with worse baseline renal function and patients with worsening renal failure, particularly with spironolactone.</p> <p>Secondary:</p>

vs  furosemide 25 mg daily for 24 weeks	therapy		Not reported	furosemide group (P<0.01).  There was no significant difference in serum potassium level between treatment groups.  No serious adverse effects were observed in either of the study groups.  Secondary: Not reported
Lee et al. <sup>60</sup> (2013)  Patients receiving spironolactone  vs  patients not receiving spironolactone	OBS  Patients with newly diagnosed HF with documented LVEF of <40% who had no aldosterone receptor antagonist use in the 12 months before study entry	N=2358  Median follow-up of 2.5 years	Primary: all-cause mortality, all-cause hospitalization, severe hyperkalemia, and acute kidney injury  Secondary: Not reported	Primary: Incident spironolactone use was associated with lower crude rates of mortality (5.5 vs 9.8 per 100 person-years; P<0.01) and all-cause hospitalization (49.4 vs 56.1 per 100 person-years, P<0.05) compared with nonuse. After adjustment for differences in patient characteristics and concurrent use of other HF therapies, use of spironolactone was not significantly associated with either death (adjusted HR, 0.93; 95% CI, 0.60 to 1.44) or all-cause hospitalization (adjusted HR, 0.91; 95% CI, 0.77 to 1.08).  Crude rates of acute kidney injury were also significantly lower during periods of spironolactone use (7.2 per 100 person-years) compared with periods of nonuse (16.2 per 100 person-years). Conversely, spironolactone use was associated with higher crude rates of severe hyperkalemia (4.8 per 100 person-years) compared with nonuse (1.6 per 100 person-years, P<0.001). After adjustment for potential confounders, incident spironolactone use was associated with a higher adjusted rate of severe hyperkalemia (adjusted HR, 3.46; 95% CI, 1.97 to 6.06) but not with acute kidney injury (adjusted HR, 0.66; 95% CI, 0.42 to 1.05).  Secondary: Not reported
Inampudi et al. <sup>61</sup> (2014)  Spironolactone on discharge	OBS  hospitalized Medicare beneficiaries with HFrEF (EF <45%)	N=1140  1 year post-discharge	Primary: 30-day all-cause readmission  Secondary: 30-day all-cause	Primary: Within 30 days postdischarge, unadjusted all-cause readmissions rates were 30% and 25% for patients receiving and not receiving spironolactone, respectively. Propensity score (PS)-adjusted HR (95% CI) associated with spironolactone use was 1.41 (1.04 to 1.90).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs  No spironolactone on discharge	and advanced CKD		mortality, HF readmissions, and combined end point of all-cause mortality or all-cause readmission	Secondary: The risk of all-cause readmission (PS-adjusted HR, 1.36; 95% CI, 1.13 to 1.63) and the combined end point of all-cause readmission or all-cause mortality (PS-adjusted HR, 1.30; 95% CI, 1.09 to 1.54) during 1 year postdischarge were higher among patients in the spironolactone group.
Maisel et al. <sup>62</sup> (2014) COACH  Spironolactone-treated patients  vs  patients not treated with spironolactone	Secondary analysis  Patients enrolled in the COACH biomarker substudy	N=534  30 days	Primary: 30-day mortality and HF-related rehospitalization  Secondary: Biomarker levels (NT-proBNP, ST2, Gal-3, and creatinine)	Primary: Spironolactone significantly reduced the 30-day composite of mortality and HF-related rehospitalization (HR, 0.538; 95% CI, 0.299 to 0.968; P=0.039).  Secondary: Elevated NT-proBNP, creatinine, and ST2 were associated with increased 30-day mortality and HF-related hospitalizations. Spironolactone treatment was significantly beneficial in groups with elevations of Gal-3, ST-2, NT-proBNP, or creatinine (P=0.037, 0.007, 0.035, and 0.009, respectively). In contrast, spironolactone treatment effects were not significant for groups with lower levels of any biomarker.
<b>Hyperaldosteronism</b>				
Karagiannis et al. <sup>63</sup> (2008)  Eplerenone 25 mg BID, titrated up to 200 mg/day if blood pressure remained $\geq$ 140/90 mm Hg  vs  spironolactone 25 mg BID, titrated up to 400 mg/day if blood pressure remained $\geq$ 140/90 mm Hg	OL, PRO, RCT  Patients with bilateral hyperaldosteronism	N=34  16 weeks	Primary: Percentage of patients whose blood pressure <140/90 mm Hg at week 16  Secondary: Adverse events	Primary: At 16 weeks, 76.5 and 82.4% of spironolactone- and eplerenone-treated patients, respectively, exhibited reductions in blood pressure to <140/90 mm Hg (P=1.00).  Secondary: Serum potassium levels were normalized with both treatments after four weeks of therapy (P value not reported). Mild hyperkalemia was noted in two spironolactone 400 mg-treated patients and in three eplerenone 150 mg-treated patients.  Two spironolactone-treated patients reported bilateral gynecomastia at week 16 (P value not reported). Switching from spironolactone 400 mg/day to eplerenone 150 mg/day was effective in resolving gynecomastia symptoms without disrupting blood pressure control.

White et al. <sup>67</sup> (2003)  Eplerenone 25 mg QD  vs  eplerenone 50 mg QD  vs  eplerenone 100 mg QD  vs  eplerenone 200 mg BID  vs  placebo	DB, MC, RCT  Adult patients with untreated HTN and seated SBP <180 mm Hg, DBP between 95 to 110 mm Hg, and the 24 hour mean DBP ≥85 mm Hg	N=400  12 weeks	Primary: Mean change from baseline in seated DBP at 12 weeks  Secondary: Change from baseline in SBP, 24 hour SBP and DBP, heart rate, adverse events	Primary: Eplerenone 50, 100 and 200 mg-treated patients experienced significant mean reductions in DBP from baseline compared to placebo (P≤0.01). The reduction in BP in eplerenone 25 mg-treated patients failed to meet significance (P=0.10).  Secondary: Eplerenone 50, 100 and 200 mg-treated patients experienced significant mean reductions in SBP from baseline compared to placebo (P≤0.01).  All eplerenone-treated patients experienced significant reductions in 24 hour ambulatory blood pressure measurements compared to placebo (P<0.006 for SBP and P<0.005 for DBP).  There were no significant differences from baseline in 24 hour mean heart rate with any eplerenone-treated patient compared to placebo (P value not reported).  Treatment emergent adverse events were reported in 48 and 49% of eplerenone- and placebo-treated patients. None of the adverse events were significantly different between the treatments (P value not reported). Two cases of impotence, gynecomastia, menstrual abnormalities and female breast pain were reported during the trial; one case occurred in a placebo-treated patient and the other in an eplerenone 100 mg/day-treated patient.
Krum et al. <sup>68</sup> (2002)  Eplerenone 50 to 100 mg/day  vs  placebo  All patients were receiving	DB, MC, PG, RCT  Patients 18 to 85 years of age taking an ACE inhibitor or an ARB for mild to moderate HTN (DBP ≥95 but <110 mm Hg and SBP <180 mm Hg), with potassium >3 mEq/L but ≤5 mEq/L	N=341  8 weeks	Primary: Mean change from baseline in trough cuff seated DBP and SBP at week eight  Secondary: Percentage of responders (DBP <90 mm Hg or exhibited a ≥10	Primary: Eplerenone-treated patients exhibited a significant mean reduction from baseline in SBP compared to placebo-treated patients at eight weeks of therapy (P≤0.05), regardless of concurrent ACE inhibitor or ARB use.  While eplerenone plus ARB-treated patients exhibited a significant mean reduction from baseline in DBP compared to ARB-treated patients at week eight (P≤0.05), eplerenone plus ACE inhibitor-treated patients experienced a reduction in baseline DBP similar to ACE inhibitor-treated patients (P value not reported).  Secondary:

				comparable to losartan and placebo.
Hanazawa et al. <sup>74</sup> (abstract) (2011)  Spironolactone 12.5 or 25 mg/day  In addition to existing antihypertensive regimens (monotherapy with a calcium channel blocker, ACE inhibitor, or ARB).	PRO  Patients with uncontrolled HTN	N=86  Not reported	Primary: Change in baseline blood pressure  Secondary: Not reported	Primary: Morning home SBP/DBP reduction was similar among patients not controlled on a calcium channel blocker (n=30, -8.2/-2.6 mmHg), ACE inhibitor (n=22, -13.0/-4.7 mmHg), and ARB (n=34, -11.5/-5.1 mmHg).  An increase in serum potassium correlated positively with the decline in morning SBP.  Secondary: Not reported
Schersten et al. <sup>75</sup> (2002)  Spironolactone 50 mg/day  vs  spironolactone 100 mg/day  vs  spironolactone 200 mg/day  vs  placebo	RCT, SB, XO  Patients <75 years of age, with DBP 105 to 135 mm Hg, after 10 to 15 minutes of supine rest	N=45  11 months	Primary: Change from baseline in DBP and SBP, adverse effects  Secondary: Not reported	Primary: All spironolactone-treated patients exhibited a significantly reduced BP level from baseline as compared to placebo (P<0.001).  While spironolactone 200 mg/day-treated patients exhibited a significantly greater lowered mean supine SBP compared to spironolactone 50 mg/day-treated patients (P<0.05), the difference between spironolactone 50 mg- and 100 mg/day-treated patients was not significant (P value not reported).  Spironolactone 200 mg/day-treated patients exhibited a significant reduction in mean upright SBP from baseline compared to spironolactone 100 mg/day- and 50 mg/day-treated patients (P<0.01).  The difference in the lowering of DBP from baseline was not significantly different among any of the spironolactone-treated patients (P value not reported).  Spironolactone 100 mg/day-treated patients exhibited a significant increase in baseline potassium and serum creatinine concentrations (P<0.05). However, spironolactone 50 mg/day-treated patients did not exhibit a change in potassium level from baseline (P value not reported).

Oxlund et al. <sup>76</sup> (2013)  Spironolactone 25 mg (option to titrate to twice daily)  vs  placebo	DB, MC, RCT  Patients aged 30 to 74 years with blood pressure at or above 130/80 mmHg despite triple antihypertensive therapy	N=119  16 weeks	Primary: Reduction of mean SBP and DBPs  Secondary: Glycemic control, urinary albumin excretion, adverse effects	Primary: All measures of BP by office as well as ambulatory monitoring showed marginal, insignificant reductions in the placebo group and significant reductions in the spironolactone group. Maximum reduction of office BP (11.3/5.3 mmHg) was found at 8 weeks of treatment (P<0.0001), after which no further reduction was found. Mean daytime SBP/DBP at 16 weeks of follow-up was 137 (13)/75 (8) mmHg in the spironolactone group and 145 (12)/79 (7) mmHg in the placebo group, P=0.0001 for difference of systolic measures and P=0.0038 for diastolic.  Secondary: Urinary albumin/creatinine ratio was reduced significantly in the spironolactone group (P=0.001), but not in the placebo group. There was a nonsignificant decrease of eGFR in the spironolactone group. Hb1Ac did not change during intervention. The frequency of adverse events was comparable in the two groups.
Václavík et al. <sup>77</sup> (2014) ASPIRANT-EXT  Spironolactone 25 mg  vs  placebo	DB, MC, RCT  Patients with office SBP >140 mm Hg or DBP >90 mm Hg despite treatment with at least 3 antihypertensive drugs, including a diuretic	N=150  8 weeks	Primary: Comparison of the fall of daytime systolic and diastolic pressure on ABPM between the spironolactone and placebo groups after 8 weeks of treatment  Secondary: Nighttime BP, serum sodium, potassium, and creatinine, change in body weight	Primary: At 8 weeks, BP values were decreased more by spironolactone, with differences in mean fall of SBP of -9.8, -13.0, -10.5, and -9.9 mm Hg (P<0.001 for all) in daytime, nighttime, and 24-hour ambulatory BP monitoring and in the office. The respective DBP differences were -3.2, -6.4, -3.5, and -3.0 mm Hg (P=0.013, P<0.001, P=0.005, and P=0.003).  Secondary: A small comparable weight gain was observed in both study groups. With spironolactone treatment, serum sodium decreased by a median of 1.0 mmol/L, and serum potassium increased by a median 0.4 mmol/L. The mean serum potassium increased during the 8 weeks of spironolactone treatment from 4.10 to 4.49 mmol/L, the highest reached serum potassium value at 8 weeks was 5.6 mmol/L.

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
spironolactone 200 mg BID  vs  HCTZ 50 mg BID  vs  spironolactone and HCTZ 25-25 mg BID (fixed-dose combination product)				(P<0.05).  At week 12, the spironolactone and HCTZ combination group was not associated with statistically significant increases in serum potassium levels from baseline.  A dose-related risk of gynecomastia was observed in the spironolactone-treated patients. Among patients treated with spironolactone 50, 100, or 200 mg BID; 5.5, 11.8, and 40% reported gynecomastia symptoms. Of the patients randomized to spironolactone and HCTZ combination product, 7.7% reported gynecomastia symptoms.  Secondary: Not reported
Schrijver et al. <sup>81</sup> (1979)  Spironolactone 50 mg BID for 8 weeks (single drug phase), with the addition of a placebo for subsequent 4 weeks (group IA)  vs  spironolactone 50 mg BID for 8 weeks (single drug phase), subsequently HCTZ 50 mg BID was added to the regimen for an additional 4 weeks	DB  Patients, between 24 to 63 years of age, with DBP between 90 to 114 mm Hg	N=49  20 weeks (4-week placebo run-in, 8-week single drug therapy, 4-week two-drug therapy, 4-week recovery)	Primary: Change in MABP, serum potassium, uric acid level, blood glucose, blood urea nitrogen, creatinine, plasma renin activity, aldosterone, side effects  Secondary: Not reported	Primary: Following eight weeks of therapy with a single drug, all study groups exhibited a statistically significant reduction in MABP from baseline (P<0.01). There were no significant differences in MABP reduction among the study groups.  The addition of a second drug to the antihypertensive regimen was not associated with a significant improvement in MABP. At the end of the two-drug treatment period, there were no differences in MABP among any of the study groups.  Spironolactone therapy was associated with a significant decrease in serum potassium concentration from baseline (P<0.001).  Spironolactone regimens were not associated with a significant change in potassium levels from baseline.  Following eight weeks of therapy with a single drug, HCTZ-treated patients experienced a statistically significant increase in uric acid from baseline (P<0.001). Groups IIA and IIB also experienced a significant but smaller increase in uric acid level from baseline (P<0.05) with no change in groups I and IV.

	were treated with ACE inhibitors		urine albumin: creatinine ratio  Secondary: Not reported	the drug was withdrawn.  Serum potassium was not significantly affected by spironolactone therapy. There was a significant increase in serum creatinine from 0.95 before therapy to 1.03 mg/dl after spironolactone. The eGFR decreased from 81.9 to 76.8 mL/min/1.73m <sup>2</sup> .  Secondary: Not reported
Williams et al. <sup>85</sup> (2015) PATHWAY-2  Twelve weeks of once daily treatment with each of spironolactone (25 to 50 mg), bisoprolol (5 to 10 mg), doxazosin modified release (4 to 8 mg), and placebo, in addition to their baseline blood pressure drugs	DB, PC, XO  Patients 18 to 79 years of age with seated clinic SBP $\geq$ 140 mmHg (or $\geq$ 135 mmHg for patients with diabetes) and home SBP (18 readings over four days) $\geq$ 130 mmHg, despite treatment for at least three months with maximally tolerated doses of three drugs (an ACE or ARB, a CCB, and a diuretic)	N=335  12 months	Primary: Average home SBP, recorded in the morning and the evening in triplicate, on four consecutive days before study visits  Secondary: Clinic SBP, BP control rates, adverse events	Primary: The average reduction in home SBP by spironolactone was significantly greater compared to placebo (-8.70 mmHg; 95% CI, -9.72 to -7.69; P<0.0001), to the mean of the other two active treatments (doxazosin and bisoprolol; -4.26; 95% CI, -5.13 to -3.38; P<0.0001), and to the individual treatments; versus doxazosin (-4.03; 95% CI, -5.04 to -3.02; P<0.0001) and versus bisoprolol (-4.48; 95% CI, -5.50 to -3.46; P<0.0001).  Secondary: The results for seated clinic SBP largely mirror those seen with home SBP except that there was a large placebo effect on clinic BP that was not seen with home BP measurement.  Overall 219 (68.9%; 95% CI, 63.6 to 73.8) of 314 patients achieved target home SBP of <135 mmHg. 58% of patients had their BP controlled with spironolactone, which was significantly greater than rates for other treatments (P<0.001 when compared to doxazosin, bisoprolol, and placebo). Most patients who were controlled by doxazosin or bisoprolol had a still greater fall in blood pressure on spironolactone, which was consequently the most effective treatment in almost 60% of patients. This was at least three times the proportion in whom doxazosin or bisoprolol were the most effective.  All active treatments were well tolerated with similar low rates of adverse events and withdrawals due to adverse events.

**Additional Evidence**

Dose Simplification

Ludbrook et al. evaluated the differences in blood pressure control and adverse events with spironolactone 300 to 400 mg administered either once daily or in in divided doses. Both administration schedules were associated with comparable systolic and diastolic blood pressure reductions. None of the regimens reduced the incidence of adverse effects (85% in both groups).<sup>92</sup>

Stable Therapy

Impact on Physician Visits

A search of Medline and PubMed did not reveal data pertinent to this topic.

**IX. Cost**

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of '\$' signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 9. Relative Cost of the Mineralocorticoid (Aldosterone) Receptor Antagonists**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost

\*Generic is available in at least one dosage form or strength.  
HCTZ=hydrochlorothiazide

**X. Conclusions**

The mineralocorticoid (aldosterone) receptor antagonists, eplerenone and spironolactone, are approved for the treatment of hypertension.<sup>3-6</sup> Eplerenone is also indicated to improve survival in patients with left ventricular systolic dysfunction (ejection fraction ≤40%) and clinical evidence of congestive heart failure after an acute

myocardial infarction.<sup>5</sup> Spironolactone is approved for the management of hyperaldosteronism, hypokalemia, and edema associated with congestive heart failure, cirrhosis, or the nephrotic syndrome. It is also indicated for patients with severe heart failure (NYHA class III to IV) to increase survival, and to reduce the need for hospitalization for heart failure when used in addition to standard therapy.<sup>3</sup> Spironolactone is now available as an oral suspension. Of note, Carospir<sup>®</sup> is not therapeutically equivalent to Aldactone<sup>®</sup>.<sup>4</sup> Spironolactone is available as single entity agents, as well as in combination with hydrochlorothiazide as a fixed-dose combination product.

Finerenone is a novel, non-steroidal, selective mineralocorticoid receptor antagonist indicated to reduce the risk of sustained eGFR decline, end stage kidney disease, cardiovascular death, non-fatal myocardial infarction, and hospitalization for heart failure in adult patients with CKD associated with T2D.<sup>7</sup> All of the mineralocorticoid (aldosterone) receptor antagonist products are available in a generic formulation except for finerenone.

There are several national and international guidelines that provide recommendations regarding the use of the mineralocorticoid (aldosterone) receptor antagonists.<sup>10-30</sup> For the treatment of heart failure, a mineralocorticoid (aldosterone) receptor antagonist is routinely recommended in addition to standard therapy (ACE inhibitor or ARB, and  $\beta$ -blocker) in patients with symptoms and an LVEF  $\leq 35\%$ . A mineralocorticoid (aldosterone) receptor antagonist is also recommended following a myocardial infarction in patients with an LVEF  $\leq 40\%$  who also have either diabetes or heart failure. Once again, therapy should be in addition to standard heart failure therapy (ACE inhibitor or ARB, and  $\beta$ -blocker).<sup>18-19</sup> There are several national and international organizations that have published guidelines on the treatment of hypertension. Most of the guidelines do not address the use of the mineralocorticoid (aldosterone) receptor antagonists. Thiazide-type diuretics are frequently recommended as initial therapy in patients with uncomplicated hypertension.<sup>20-26</sup> According to the National Heart, Lung, and Blood Institute's Eighth Report of The Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 8), thiazide-type diuretics should be utilized first-line for most patients with hypertension, either alone or in combination with another antihypertensive from a different medication class (e.g., ACE inhibitors, ARBs,  $\beta$ -blockers, calcium channel blockers).<sup>20</sup> Several guidelines consistently recommend that the selection of an antihypertensive agent be based on compelling indications for use.<sup>20-26</sup> Most patients will require more than one antihypertensive agent to achieve blood pressure goals.<sup>20-26</sup>

For the treatment of cirrhosis and ascites, spironolactone is recommended as first line therapy in addition to sodium restriction.<sup>29</sup> Spironolactone is also recommended for the treatment of patients with unilateral primary aldosteronism (in lieu of surgery) and in those with bilateral adrenal disease. Eplerenone is considered an alternative treatment option, especially in men who experience erectile dysfunction and gynecomastia with spironolactone therapy.<sup>30</sup>

For diabetic kidney disease, guidelines recommend the use of ACEIs or ARBs in patients who have CKD and albuminuria and have more recently recommended the addition of SGLT2 inhibitor. The ADA guidelines recommend a nonsteroidal mineralocorticoid receptor antagonist (finerenone) to reduce CKD progression and cardiovascular events in patients with CKD who are at increased risk for cardiovascular events or CKD progression and are unable to use a SGLT2 inhibitor.<sup>28</sup>

Eplerenone and spironolactone have been shown to reduce cardiovascular morbidity and mortality in patients with heart failure when added to standard therapy.<sup>42-47,49-54</sup> These agents have also been shown to effectively lower blood pressure.<sup>65-86</sup> Only one trial in hypertensive patients included both eplerenone and spironolactone. Both products significantly decreased blood pressure compared to placebo; however, statistical analyses were not performed among the two agents. The authors noted that there was a greater reduction in blood pressure with spironolactone 50 mg twice daily compared to eplerenone 50 mg twice daily. This information suggests that eplerenone may only be 50 to 75% as potent as spironolactone.<sup>69</sup> Most patients will require more than one antihypertensive agent to achieve blood pressure goals.<sup>20-27</sup> The use of a fixed-dose combination product may simplify the treatment regimen and improve adherence.<sup>22-23,26,90</sup> However, there are no prospective, randomized trials that have demonstrated better clinical outcomes with a fixed-dose combination product compared to the coadministration of the individual components as separate formulations. Several studies in diabetic and non-diabetic patients with renal disease have demonstrated a reduction in proteinuria with the addition of spironolactone to existing ACE inhibitor and/or ARB therapy.<sup>31-41</sup> Studies have demonstrated efficacy of finerenone compared to placebo in reducing incidence of composite cardiovascular outcome including time to cardiovascular death, myocardial infarction, stroke, or hospitalization for heart failure, among patients with CKD and T2D.<sup>87,88</sup>

In general, adverse events are similar with the mineralocorticoid (aldosterone) receptor antagonists and both agents can increase serum potassium levels. While eplerenone is a selective aldosterone receptor antagonist, spironolactone may also antagonize glucocorticoid, progesterone, and androgen receptors. Consequently, there is an increased risk of steroid-related adverse effects with spironolactone (e.g., gynecomastia, impotence, menstrual abnormalities).<sup>1-6</sup> Finerenone is a novel, non-steroidal, selective mineralocorticoid (aldosterone) receptor antagonists that appears to be more selective for the mineralocorticoid receptor. Finerenone has shown to reduce albuminuria in T2D patients with CKD, while revealing only a low risk of hyperkalemia.<sup>7-9</sup>

There is insufficient evidence to support that one brand mineralocorticoid (aldosterone) receptor antagonist is safer or more efficacious than another. Formulations without a generic alternative should be managed through the medical justification portion of the prior authorization process.

Therefore, all brand mineralocorticoid (aldosterone) receptor antagonists within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

## **XI. Recommendations**

No brand mineralocorticoid (aldosterone) receptor antagonist is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

**Alabama Medicaid Agency  
Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Renin Inhibitors  
AHFS Class 243240  
May 4, 2022**

**I. Overview**

The renin-angiotensin-aldosterone system (RAAS) is the most important component in the homeostatic regulation of blood pressure.<sup>1</sup> Excessive activity of the RAAS may lead to hypertension, as well as fluid and electrolyte disorders. Renin catalyzes the conversion of angiotensinogen to angiotensin I, which is the first and rate-limiting step of the RAAS.<sup>1-3</sup> Angiotensin I is then cleaved to angiotensin II by angiotensin-converting enzyme (ACE). Angiotensin II may also be generated through other pathways (angiotensin I convertase). Through a negative feedback mechanism, angiotensin II inhibits renin release. Angiotensin II can increase blood pressure by direct vasoconstriction, as well as through actions on the brain and autonomic nervous system. In addition, angiotensin II induces aldosterone synthesis from the adrenal cortex, leading to sodium and water reabsorption. Angiotensin II exerts other detrimental effects, including ventricular hypertrophy, remodeling and myocyte apoptosis.<sup>4,5</sup>

Aliskiren is the only renin inhibitor that is currently available and it is approved for the treatment of hypertension. It decreases plasma renin activity and inhibits the conversion of angiotensinogen to angiotensin I. It is unknown if aliskiren affects other RAAS components, such as ACE or non-ACE pathways. Aliskiren is available as a single entity product, as well as in combination with hydrochlorothiazide.<sup>6-7</sup> Previously, aliskiren was available in combination with valsartan under the name Valtorna®; however, this agent was removed from the market in 2012 due to evidence suggesting an increased risk of renal impairment, hypotension, and hyperkalemia in patients taking aliskiren and ACE inhibitors or ARBs concomitantly.<sup>8</sup> Combination products containing aliskiren and amlodipine, with or without hydrochlorothiazide, are also no longer available.

The renin inhibitors that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. Aliskiren is available in a generic formulation. This class was last reviewed in February 2020.

**Table 1. Renin Inhibitors Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
<b>Single Entity Agents</b>			
Aliskiren	tablet	Tekturna®*	aliskiren
<b>Combination Products</b>			
Aliskiren and hydrochlorothiazide	tablet	Tekturna HCT®	none

\*Generic is available in at least one dosage form or strength.  
PDL=Preferred Drug List

**II. Evidence-Based Medicine and Current Treatment Guidelines**

Current treatment guidelines that incorporate the use of the renin inhibitors are summarized in Table 2.

**Table 2. Treatment Guidelines Using the Renin Inhibitors**

Clinical Guideline	Recommendations
Eighth Joint National Committee (JNC 8): <b>2014 Evidence-based Guideline for the Management of High Blood Pressure in Adults (2014)</b> <sup>9</sup>	<ul style="list-style-type: none"> <li>Pharmacologic treatment should be initiated in patients <math>\geq 60</math> years of age to lower blood pressure at systolic blood pressure <math>\geq 150</math> mm Hg or diastolic blood pressure <math>\geq 90</math> mm Hg and to a goal systolic blood pressure <math>&lt; 150</math> mm Hg and goal diastolic blood pressure <math>&lt; 90</math> mm Hg. Adjustment of treatment is not necessary if treatment results in lower blood pressure and treatment is well tolerated and without adverse effects on health or quality of life.</li> <li>In patients <math>&lt; 60</math> years of age, pharmacologic treatment should be initiated to lower blood pressure at diastolic blood pressure <math>\geq 90</math> mm Hg to a goal diastolic blood pressure <math>&lt; 90</math> mm Hg.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure <math>\geq 150</math> mm Hg to a goal diastolic blood pressure &lt;140 mm Hg.</li> <li>• For patients <math>\geq 18</math> years of age with chronic kidney disease or diabetes, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure <math>\geq 140</math> mm Hg or diastolic blood pressure <math>\geq 90</math> mm Hg and to a goal systolic blood pressure &lt;140 mm Hg and goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• Initial antihypertensive treatment for the general nonblack population, including those with diabetes, should include thiazide-type diuretic, calcium channel blocker (CCB), ACE inhibitor, or ARB.</li> <li>• Initial antihypertensive treatment for the general black population, including those with diabetes, should include thiazide-type diuretic or CCB.</li> <li>• For patients <math>\geq 18</math> years of age with chronic kidney disease regardless of race or diabetes status, initial (or add-on) treatment should include an ACE inhibitor or ARB to improve kidney outcomes.</li> <li>• The main goal of antihypertensive treatment is to attain and maintain goal blood pressure.</li> <li>• If goal blood pressure is not attained within a month of treatment, the dose of the initial drug should be increased or second drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• If goal is not achieved with two drugs, a third drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• An ACE inhibitor and ARB should not be used together.</li> <li>• Antihypertensive classes can be used if the patient is unable to achieve goal blood pressure with three agents or had a contraindication to a preferred class.</li> <li>• If blood pressure is not able to be achieved or in complicated patients, referral to a hypertension specialist may be indicated.</li> </ul>
<p>International Society of Hypertension: <b>Global Hypertension Practice Guidelines (2020)</b><sup>10</sup></p>	<p><b>Lifestyle modifications</b></p> <ul style="list-style-type: none"> <li>• Lifestyle modification is the first line of antihypertensive treatment.</li> <li>• Salt reduction: Reduce salt added when preparing foods, and at the table. Avoid or limit consumption of high salt foods such as soy sauce, fast foods and processed food including breads and cereals high in salt.</li> <li>• Healthy diet: Eating a diet that is rich in whole grains, fruits, vegetables, polyunsaturated fats and dairy products and reducing food high in sugar, saturated fat and trans fats, such as the DASH diet.</li> <li>• Healthy drinks: Moderate consumption of coffee, green and black tea. Other beverages that can be beneficial include karkadé (hibiscus) tea, pomegranate juice, beetroot juice and cocoa.</li> <li>• Moderation of alcohol consumption: The recommended daily limit for alcohol consumptions is 2 standard drinks for men and 1.5 for women (10 g alcohol/standard drink). Avoid binge drinking.</li> <li>• Weight reduction: Body weight control is indicated to avoid obesity. Particularly abdominal obesity should be managed. Ethnic-specific cut-offs for BMI and waist circumference should be used. Alternatively, a waist-to-height ratio &lt;0.5 is recommended for all populations.</li> <li>• Smoking cessation: Smoking is a major risk factor for cardiovascular disease (CVD), COPD and cancer. Smoking cessation and referral to smoking cessation programs are advised.</li> <li>• Regular physical activity: Studies suggest that regular aerobic and resistance exercise may be beneficial for both the prevention and treatment of hypertension. Moderate intensity aerobic exercise (walking, jogging, cycling, yoga, or swimming) for 30 minutes on five to seven days per week Strength training also can help reduce blood pressure. Performance of resistance/strength exercises on two to three days per week.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Reduce stress and induce mindfulness: Stress should be reduced and mindfulness or meditation introduced into the daily routine.</li> <li>• Reduce exposure to air pollution and cold temperature: Evidence from studies support a negative effect of air pollution on blood pressure in the long-term.</li> </ul> <p><b>Pharmacological Treatment</b></p> <ul style="list-style-type: none"> <li>• Ideal characteristics of drug treatment               <ul style="list-style-type: none"> <li>○ Treatments should be evidence-based in relation to morbidity/mortality prevention.</li> <li>○ Use a once-daily regimen which provides 24-hour blood pressure control.</li> <li>○ Treatment should be affordable and/or cost-effective relative to other agents.</li> <li>○ Treatments should be well-tolerated.</li> <li>○ Evidence of benefits of use of the medication in populations to which it is to be applied.</li> </ul> </li> <li>• General scheme for drug treatment               <ul style="list-style-type: none"> <li>○ Lifestyle modification is the first line of antihypertensive treatment.</li> <li>○ Grade 1 hypertension (BP 140 to 159/ 90 to 99): Immediate drug treatment in high-risk patients or those with CVD, chronic kidney disease (CKD), diabetes mellitus (DM), or hypertension-mediated organ damage (HMOD). Drug treatment after three to six months of lifestyle intervention if BP still not controlled in low to moderate risk patients.</li> <li>○ Grade 2 hypertension (BP <math>\geq</math>160/100): Immediate drug treatment in all patients.</li> </ul> </li> <li>• Core drug-treatment strategy               <ul style="list-style-type: none"> <li>○ Step 1: Dual low-dose combination (ACE inhibitor or ARB plus dihydropyridine-calcium channel blockers (DHP-CCB)); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance; consider ACE/ARB plus DHP-CCB or DHP-CCB plus thiazide-like diuretics in black patients.</li> <li>○ Step 2: Dual full-dose combination (ACE inhibitor or ARB plus DHP-CCB); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance.</li> <li>○ Step 3: Triple combination (ACE/ARB plus DHP-CCB plus thiazide-like diuretic).</li> <li>○ Step 4, resistant hypertension: triple combination plus spironolactone or other drug, alternatives include amiloride, doxazosin, eplerenone, clonidine, or <math>\beta</math>-blocker. Caution with spironolactone or other potassium sparing diuretics when estimated GFR <math>&lt;</math>45 mL/min/1.73m<sup>2</sup> or K<sup>+</sup> <math>&gt;</math>4.5 mmol/L.</li> <li>○ Consider <math>\beta</math>-blockers at any treatment step when there is a specific indications for their use, e.g., heart failure, angina, post-MI, atrial fibrillation, or younger women planning pregnancy or pregnant.</li> </ul> </li> </ul>
<p>Hypertension Canada: 2020 Guidelines for the Prevention, Diagnosis, Risk Assessment, and Treatment of Hypertension in Adults and Children (2020)<sup>11</sup></p>	<p><b>Indications for drug therapy for adults with hypertension without compelling indications for specific agents</b></p> <ul style="list-style-type: none"> <li>• Antihypertensive therapy should be prescribed for average diastolic blood pressure (DBP) measurements of <math>\geq</math>100 mmHg or average systolic blood pressure (SBP) measurements of <math>\geq</math>160 mmHg in patients without macrovascular target organ damage or other cardiovascular risk factors.</li> <li>• Antihypertensive therapy should be strongly considered for average DPB readings <math>\geq</math>90 mmHg or for average SBP readings <math>\geq</math>140 mmHg in the presence of macrovascular target organ damage or other independent cardiovascular risk</li> </ul>

Clinical Guideline	Recommendations
	<p>factors.</p> <ul style="list-style-type: none"> <li>• For high-risk patients, aged 50 years or older, with SBP levels <math>\geq 130</math> mmHg, intensive management to target a SBP <math>&lt; 120</math> mmHg should be considered. Patient selection for intensive management is recommended and caution should be taken in certain high-risk groups.</li> </ul> <p><u>Indications for drug therapy for adults with diastolic and with or without systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be with either monotherapy or single pill combination (SPC). <ul style="list-style-type: none"> <li>○ Recommended monotherapy choices are: <ul style="list-style-type: none"> <li>▪ A thiazide/thiazide-like diuretic, with longer-acting diuretics preferred;</li> <li>▪ A <math>\beta</math>-blocker (in patients <math>&lt; 60</math> years of age);</li> <li>▪ An angiotensin-converting enzyme (ACE) inhibitor (in nonblack patients);</li> <li>▪ An angiotensin receptor blocker (ARB); or</li> <li>▪ A long-acting calcium channel blocker (CCB).</li> </ul> </li> <li>○ Recommended SPC choices are those in which an ACE inhibitor is combined with a CCB, ARB with a CCB, or ACE inhibitor or ARB with a diuretic.</li> <li>○ Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> </ul> </li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line choices. Useful choices include a thiazide/thiazide-like diuretic or CCB with either: ACE inhibitor, ARB, or <math>\beta</math>-blocker. Caution should be exercised in combining a nondihydropyridine CCB and a <math>\beta</math>-blocker. The combination of an ACE inhibitor and an ARB is not recommended.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other antihypertensive drugs may be added.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated hypertension; <math>\beta</math>-blockers are not recommended as first-line therapy for uncomplicated hypertension in patients <math>\geq 60</math> years of age; and ACE inhibitors are not recommended as first-line therapy for uncomplicated hypertension in black patients. However, these agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Indications for drug therapy for adults with isolated systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be single-agent therapy with a thiazide/thiazide-like diuretic, a long-acting dihydropyridine CCB, or an ARB. If there are adverse effects, another drug from this group should be substituted. Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line options.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other classes of drugs (such as <math>\alpha</math>-blockers, ACE inhibitors, centrally acting agents, or nondihydropyridine CCBs) may be combined or substituted.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated isolated systolic hypertension; and <math>\beta</math>-blockers are not recommended as first-line therapy for isolated systolic hypertension in patients <math>\geq 60</math> years of age. However, both agents may be used in patients with certain comorbid conditions or in</li> </ul>

Clinical Guideline	Recommendations
	<p>combination therapy.</p> <p><u>Guidelines for hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• For most hypertensive patients with CAD, an ACE inhibitor or ARB is recommended.</li> <li>• For hypertensive patients with CAD, but without coexisting systolic heart failure, the combination of an ACE inhibitor and ARB is not recommended.</li> <li>• For high-risk hypertensive patients, when combination therapy is being used, choices should be individualized. The combination of an ACE inhibitor and a dihydropyridine CCB is preferable to an ACE inhibitor and a thiazide/thiazide-like diuretic in selected patients.</li> <li>• For patients with stable angina pectoris but without previous heart failure, myocardial infarction, or coronary artery bypass surgery, either a <math>\beta</math>-blocker or CCB can be used as initial therapy.</li> <li>• Short-acting nifedipine should not be used.</li> <li>• When decreasing SBP to target levels in patients with established CAD (especially if isolated systolic hypertension is present), be cautious when the DBP is <math>\leq 60</math> mmHg because of concerns that myocardial ischemia might be exacerbated, especially in patients with left ventricular hypertrophy (LVH).</li> </ul> <p><u>Guidelines for patients with hypertension who have had a recent myocardial infarction</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should include a <math>\beta</math>-blocker as well as an ACE inhibitor.</li> <li>• An ARB can be used if the patient is intolerant of an ACE inhibitor.</li> <li>• CCBs may be used in patients after myocardial infarction when <math>\beta</math>-blockers are contraindicated or not effective. Nondihydropyridine CCBs should not be used when there is heart failure, evidenced by pulmonary congestion on examination or radiography.</li> </ul> <p><u>Treatment of hypertension in association with heart failure</u></p> <ul style="list-style-type: none"> <li>• In patients with systolic dysfunction (ejection fraction <math>&lt;40\%</math>), ACE inhibitors and <math>\beta</math>-blockers are recommended for initial therapy. Aldosterone antagonists (mineralocorticoid receptor antagonists) may be combined in treatment for patients with a recent cardiovascular hospitalization, acute myocardial infarction, elevated B-type natriuretic peptide or N-terminal pro-B-type natriuretic peptide level, or New York Heart Association (NYHA) Class II-IV symptoms. Careful monitoring for hyperkalemia is recommended when combining an aldosterone antagonist with ACE inhibitor or ARB treatment. Other diuretics are recommended as additional therapy if needed. Beyond considerations of BP control, doses of ACE inhibitors or ARBs should be titrated to those reported to be effective in trials unless adverse effects become manifest.</li> <li>• An ARB is recommended if ACE inhibitors are not tolerated.</li> <li>• A combination of hydralazine and isosorbide dinitrate is recommended if ACE inhibitors and ARBs are contraindicated or not tolerated.</li> <li>• For hypertensive patients whose BP is not controlled, an ARB may be combined with an ACE inhibitor and other antihypertensive drug treatment. Careful monitoring should be used if combining an ACE inhibitor and an ARB because of potential adverse effects such as hypotension, hyperkalemia, and worsening renal function. Additional therapies may also include dihydropyridine CCBs.</li> <li>• An angiotensin receptor-neprilysin inhibitor (ARNI) should be used in place of an ACE inhibitor or ARB for patients with HFrEF (<math>&lt;40\%</math>) who remain symptomatic despite treatment with appropriate dose of guideline directed HF therapy. Eligible patients must have a serum potassium <math>&lt;5.2</math> mmol/L, an eGFR <math>\leq 30</math> mL/min/1.73m<sup>2</sup> and close surveillance of serum potassium and creatinine.</li> </ul>

Clinical Guideline	Recommendations
	<p><b>Treatment of hypertension in association with stroke</b></p> <ul style="list-style-type: none"> <li>• BP management in acute ischemic stroke (onset to 72 hours)               <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> <li>• BP management after acute ischemic stroke               <ul style="list-style-type: none"> <li>○ Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack.</li> <li>○ After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently &lt;140/90 mmHg.</li> <li>○ Treatment with an ACE inhibitor and thiazide/thiazide-like diuretic combination is preferred.</li> <li>○ For patients with stroke, the combination of an ACE inhibitor and ARB is not recommended.</li> </ul> </li> <li>• BP management in hemorrhagic stroke (onset to 72 hours)               <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> </ul> <p><b>Treatment of hypertension in association with LVH</b></p> <ul style="list-style-type: none"> <li>• Hypertensive patients with LVH should be treated with antihypertensive therapy to decrease the rate of subsequent cardiovascular events.</li> <li>• The choice of initial therapy can be influenced by the presence of LVH. Initial therapy can be drug treatment using ACE inhibitors, ARBs, long-acting CCBs, or thiazide/thiazide-like diuretics. Direct arterial vasodilators such as hydralazine or minoxidil should not be used.</li> </ul> <p><b>Treatment of hypertension in association with nondiabetic chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>• Individualize BP targets in patients with chronic kidney disease. Consider intensive targets (SBP &lt;120 mmHg) in appropriate patients.</li> <li>• For patients with hypertension and proteinuric chronic kidney disease (urinary protein &gt;150 mg per 24 hours or albumin to creatinine ratio &gt;30 mg/mmol), initial therapy should be an ACE inhibitor or an ARB if there is intolerance to ACE inhibitors.</li> <li>• In most cases, combination therapy with other antihypertensive agents might be needed to reach target BP levels.</li> <li>• The combination of an ACE inhibitor and ARB is not recommended for patients with nonproteinuric chronic kidney disease.</li> </ul> <p><b>Treatment of hypertension in association with renovascular disease</b></p> <ul style="list-style-type: none"> <li>• Patients with hypertension attributable to atherosclerotic renal artery stenosis should be primarily medically managed because renal angioplasty and stenting offers no benefit over optimal medical therapy alone.</li> <li>• Renal artery angioplasty and stenting for atherosclerotic hemodynamically significant renal artery stenosis could be considered for patients with uncontrolled hypertension resistant to maximally tolerated pharmacotherapy, progressive renal function loss, and acute pulmonary edema.</li> <li>• Patients with confirmed renal fibromuscular dysplasia (FMD) should be referred to a hypertension specialist.</li> <li>• Renal artery angioplasty without stenting is recommended for treatment of FMD-related renal artery stenosis. Stenting is not recommended unless needed because of a periprocedural dissection. Surgical revascularization should be considered in cases of complex lesions less amenable to angioplasty, stenosis associated with complex aneurysm, and restenosis despite two unsuccessful attempts of angioplasty.</li> </ul> <p><b>Treatment of hypertension in association with diabetes mellitus</b></p> <ul style="list-style-type: none"> <li>• Persons with diabetes mellitus should be treated to attain SBP of &lt;130 mmHg and DBP of &lt;80 mmHg.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• For persons with cardiovascular or kidney disease, including microalbuminuria, or with cardiovascular risk factors in addition to diabetes and hypertension, an ACE inhibitor or an ARB is recommended as initial therapy.</li> <li>• For persons with diabetes and hypertension not included in other guidelines in this section, appropriate choices include (in alphabetical order): ACE inhibitors, ARBs, dihydropyridine CCBs, and thiazide/thiazide-like diuretics.</li> <li>• If target BP levels are not achieved with standard-dose monotherapy, additional antihypertensive therapy should be used. For persons in whom combination therapy with an ACE inhibitor is being considered, a dihydropyridine CCB is preferable to a thiazide/thiazide-like diuretic.</li> </ul> <p><u>Resistant hypertension</u></p> <ul style="list-style-type: none"> <li>• Resistant hypertension is defined as BP above target despite three or more BP-lowering drugs at optimal doses preferably including a diuretic (and usually a renin-angiotensin-aldosterone system blocker and a CCB).</li> <li>• Accurate office and out-of-office BP measurement is essential.</li> <li>• Other reasons for apparent resistant hypertension should be eliminated before diagnosing true resistant hypertension, including nonadherence, white coat effect, and secondary hypertension.</li> <li>• Pharmacotherapy with the additional use of spironolactone, bisoprolol, doxazosin, amiloride, eplerenone, or clonidine with the baseline regimen decreases BP significantly, with the greatest BP-lowering shown with spironolactone.</li> <li>• Patients with resistant hypertension should be referred to providers with expertise in diagnosis and management of hypertension.</li> </ul> <p><u>Hypertension and pediatrics</u></p> <ul style="list-style-type: none"> <li>• BP should be measured regularly in children three years of age or older; the auscultatory method is the gold-standard at present.</li> <li>• Initial therapy should be monotherapy, with an ACE inhibitor or ARB (not first-line in black children), or a long-acting dihydropyridine CCB.</li> <li>• The treatment goal is systolic and diastolic office BP and/or ABPM &lt; 95th percentile or &lt;90<sup>th</sup> percentile in children with risk factors or target organ damage.</li> <li>• Complex cases should be referred to an expert in pediatric hypertension.</li> </ul> <p><u>Hypertension and pregnancy</u></p> <ul style="list-style-type: none"> <li>• Up to 7% of pregnancies are complicated by a hypertensive disorder of pregnancy, and approximately 5% of women will have chronic hypertension when they become pregnant.</li> <li>• The prevalence of hypertension in pregnancy is expected to increase with women becoming pregnant later in their reproductive years and the increasing prevalence of cardiovascular comorbidities such as increased preconception body mass index and maternal diabetes.</li> <li>• The possibility of pregnancy should be considered when managing women with hypertension who are of reproductive age.</li> <li>• Preconception counselling should be offered to all women with hypertension who are considering pregnancy.</li> <li>• ACE inhibitor and ARB therapy should be avoided before conception and during pregnancy unless there is a compelling indication for their use (i.e., proteinuric kidney disease).</li> <li>• Hypertension during pregnancy can increase the risk of adverse maternal and fetal outcomes, including an increased risk of preeclampsia, placental abruption, prematurity, small for gestational age infants, stillbirth, and maternal renal and retinal injury, thus generally requires involvement of an interdisciplinary team including obstetrical care providers.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Antihypertensive therapy is recommended for average SBP measurements of <math>\geq 140</math> mmHg or DBP measurements of <math>\geq 90</math> mmHg in pregnant women with chronic hypertension, gestational hypertension, or preeclampsia. Initial antihypertensive therapy should be monotherapy from the following first-line drugs: oral labetalol, oral methyldopa, long-acting oral nifedipine, or other oral b-blockers (acebutolol, metoprolol, pindolol, and propranolol). Other antihypertensive drugs can be considered as second-line drugs including: clonidine, hydralazine, and thiazide diuretics.</li> <li>• Women with severe hypertension with SBP <math>\geq 160</math> mmHg or DBP <math>\geq 110</math> mmHg in pregnancy or postpartum require urgent antihypertensive therapy because it is considered an obstetrical emergency.</li> <li>• Antihypertensive drugs used in breastfeeding women include: labetalol, methyldopa, long-acting nifedipine, enalapril, or captopril.</li> </ul>
<p>European Society of Hypertension/ European Society of Cardiology: <b>2018 Guidelines for the management of arterial hypertension (2018)</b><sup>12</sup></p>	<p><u>Treatment strategies and choice of antihypertensive drugs</u></p> <ul style="list-style-type: none"> <li>• Diuretics (including thiazides, chlorthalidone, and indapamide), <math>\beta</math>-blockers, calcium channel blocker (CCB), angiotensin-converting enzyme (ACE) inhibitors, and angiotensin receptor blockers (ARBs) are all suitable for the initiation and maintenance of antihypertensive treatment, either as monotherapy or in some combinations.</li> <li>• Some agents should be considered as the preferential choice in specific conditions because used in trials in those conditions or because of greater effectiveness in specific types of organ damage. Preferred combinations should comprise a renin-angiotensin system (RAS) blocker (either an ACE inhibitor or an ARB) with a CCB or diuretic.</li> <li>• It is recommended that beta-blockers are combined with any of the other major drug classes when there are specific clinical situations, e.g. angina, post-myocardial infarction, heart failure, or heart rate control.</li> <li>• Initiation of antihypertensive therapy with a two-drug combination may be considered in patients with markedly high baseline blood pressure (BP) or at high cardiovascular (CV) risk.</li> <li>• The combination of two antagonists of the RAS is not recommended and should be discouraged.</li> <li>• Other drug combinations should be considered and probably are beneficial in proportion to the extent of BP reduction. However, combinations that have been successfully used in trials may be preferable.</li> <li>• Combinations of two antihypertensive drugs at fixed doses in a single tablet may be recommended and favored, because reducing the number of daily pills improves adherence, which is low in patients with hypertension. Exceptions are frail older patients and those at low risk and with grade one hypertension (particularly if systolic BP is <math>&lt; 150</math> mmHg).</li> <li>• It is recommended that if BP is not controlled with a three-drug combination, treatment should be increased by the addition of spironolactone or, if not tolerated, other diuretics such as amiloride or higher doses of other diuretics, a beta-blocker, or an alpha-blocker.</li> </ul> <p><u>Treatment strategies in white-coat and masked hypertension</u></p> <ul style="list-style-type: none"> <li>• In white-coat hypertensives without additional risk factors, therapeutic intervention may be limited to lifestyle changes only, but this decision should be accompanied by close follow-up.</li> <li>• In white-coat hypertensives with a higher CV risk or hypertension-mediated organ damage, drug treatment may be considered in addition to lifestyle changes.</li> <li>• In masked hypertension, both lifestyle measures and antihypertensive drug treatment should be considered, because this type of hypertension has been consistently found to have a CV risk very close to that of in- and out-of-office hypertension.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Antihypertensive drug up-titration should be considered in treated patients whose out-of-office BP is not controlled (i.e., masked uncontrolled hypertension), because of the high CV risk of these patients.</li> </ul> <p><u>Antihypertensive treatment strategies in the elderly</u></p> <ul style="list-style-type: none"> <li>• It is recommended that older patients (<math>\geq 65</math> years) are treated with the same recommendations in non-older patient population. In very old patients (<math>\geq 80</math> years), it may be appropriate to initiate treatment with monotherapy.</li> <li>• In all older patients, when combination therapy is used, it is recommended that this is initiated at the lowest available doses. In all older patients, and especially very old or frail patients, the possible occurrence of postural BP should be closely monitored and symptoms of possible hypotensive episodes checked by ambulatory blood pressure monitoring.</li> <li>• Unless required for concomitant diseases, loop diuretics and alpha-blockers should be avoided because of their association with injurious falls.</li> <li>• Renal function should be frequently assessed to detect possible increases in serum creatinine and reductions in estimated glomerular filtration rate (eGFR) as a result of BP-related reductions in renal perfusion.</li> <li>• When treated, BP should be lowered to a systolic value of 130 to 139 mmHg and a diastolic value of <math>&lt; 80</math> mmHg if tolerated. Treated values of <math>&lt; 130</math> mmHg should be avoided.</li> </ul> <p><u>Treatment strategies in hypertensive women</u></p> <ul style="list-style-type: none"> <li>• Hormone therapy and selective estrogen receptor modulators are not recommended and should not be used for primary or secondary prevention of CVD.</li> <li>• In women with gestational hypertension, pre-existing hypertension superimposed by gestational hypertension, or with hypertension and subclinical organ damage or symptoms, initiation of drug treatments is recommended when SBP is <math>\geq 140</math> mmHg or DBP <math>\geq 90</math> mmHg. In all other cases, initiation of drug treatment is recommended when SBP is <math>\geq 150</math> mmHg or DBP is <math>\geq 95</math> mmHg.</li> <li>• Methyldopa, labetalol, and CCBs are recommended as the drugs of choice for the treatment of hypertension in pregnancy.</li> <li>• ACE inhibitors, ARBs, or direct renin inhibitors are not recommended during pregnancy.</li> <li>• SBP <math>\geq 170</math> mmHg or DBP <math>\geq 110</math> mmHg in a pregnant woman is an emergency, and admission to hospital is recommended.</li> <li>• In severe hypertension, drug treatment with intravenous (IV) labetalol, oral methyldopa, or nifedipine is recommended.</li> <li>• The recommended treatment for hypertensive crisis is IV labetalol or nicardipine and magnesium.</li> <li>• In pre-eclampsia associated with pulmonary edema, nitroglycerin given as an IV infusion is recommended.</li> <li>• In women with gestational hypertension or mild-pre-eclampsia, delivery is recommended at 37 weeks.</li> <li>• It is recommended to expedite delivery in pre-eclampsia with adverse conditions, such as visual disturbances or hemostatic disorders</li> <li>• In women at high risk of pre-eclampsia, provided they are at low risk of gastrointestinal hemorrhage, treatment with low dose aspirin from 12 weeks until delivery may be considered.</li> <li>• Methyldopa, labetalol, and nifedipine should be considered preferential antihypertensive drugs in pregnancy. Intravenous labetalol or infusion of nitroprusside should be considered in case of emergency (pre-eclampsia).</li> </ul> <p><u>Treatment strategies in patients with diabetes</u></p>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Antihypertensive drug treatment is recommended for people with diabetes when office BP is <math>\geq 140/90</math> mmHg.</li> <li>• A SBP goal <math>&lt; 130</math> mmHg is recommended in patients with diabetes and <math>&lt; 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg.</li> <li>• In older people, the target SBP range is 130 to 139 mmHg.</li> <li>• The DBP target in patients with diabetes is recommended to be <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• It is recommended to initiate treatment with a combination of a RAS blocker with a CCB or thiazide/thiazide-like diuretic.</li> <li>• It is recommended that individual drug choice takes comorbidities into account.</li> <li>• Simultaneous administration of two blockers of the RAS is not recommended and should be avoided in patients with diabetes.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with nephropathy</u></p> <ul style="list-style-type: none"> <li>• In patients with diabetic and non-diabetic CKD, it is recommended that an office BP of <math>\geq 140/90</math> mmHg be treated with lifestyle advice and BP-lowering medication.</li> <li>• In patients with diabetic or non-diabetic CKD, it is recommended to lower SBP to a range of 130 to 139 mmHg. And individualized treatments should be considered according to its tolerability and impact on renal function and electrolytes.</li> <li>• A combination of a RAS blocker with a CCB or a diuretic is recommended as initial therapy.</li> <li>• RAS blockers are more effective in reducing albuminuria than other antihypertensive agents, and are indicated in hypertensive patients in the presence of microalbuminuria or overt proteinuria.</li> <li>• Combination of two RAS blockers, though potentially more effective in reducing proteinuria, is not recommended.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with cerebrovascular disease</u></p> <ul style="list-style-type: none"> <li>• In patients with acute intracerebral hemorrhage, immediate BP lowering is not recommended for patients with SBP <math>&lt; 220</math> mmHg. In patients with SBP <math>\geq 220</math> mmHg, care acute BP lowering with IV therapy to <math>&lt; 180</math> mmHg should be considered.</li> <li>• In acute ischemic stroke, routine BP lowering with antihypertensive therapy is not recommended with the exceptions with the exceptions: in patients with acute ischemic stroke who are eligible for IV thrombolysis, BP should be carefully lowered and maintained at <math>&lt; 180/105</math> mmHg for at least the first 24 hours after thrombolysis; In patients with markedly elevated BP who do not receive fibrinolysis, drug therapy may be considered, based on clinical judgement, to reduce BP by 15% during the first 24 hours after the stroke onset.</li> <li>• In hypertensive patients with an acute cerebrovascular event, antihypertensive treatment is recommended immediately for transient ischemic attack (TIA) and after several days in ischemic stroke.</li> <li>• In all hypertensive patients with ischemic stroke or TIA, an SBP target range of 120 to 130 mmHg should be considered.</li> <li>• The recommended antihypertensive drug treatment strategy for stroke prevention is a RAS blocker plus a CCB or a thiazide-like diuretic.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with heart failure (HF) or left ventricular hypertrophy (LVH)</u></p> <ul style="list-style-type: none"> <li>• In hypertensive patients with heart failure (with reduced or preserved ejection fraction), BP-lowering treatment should be considered if <math>\geq 140/90</math> mmHg.</li> <li>• In patients with HFrEF, it is recommended that BP-lowering treatment comprises an ACE inhibitor or ARB, and a beta-blocker and a diuretic and/or</li> </ul>

Clinical Guideline	Recommendations
	<p>mineralocorticoid receptor antagonist (MRA) if required.</p> <ul style="list-style-type: none"> <li>• Dihydropyridine CCBs may be added if BP control is not achieved.</li> <li>• In patients with HFpEF, BP treatment threshold and target values should be the same as for HFrEF).</li> <li>• Because no specific drug has proven its superiority, all major agents can be used.</li> <li>• In all patients with LVH, it is recommended to treat with a RAS blocker or in combination with a CCB or diuretic and SBP should be lowered to a range of 120 to 130 mmHg.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• In patients with CAD receiving BP-lowering drugs, it is recommended to target SBP to <math>\leq 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg. In older patients, the target is an SBP range of 130 to 140 mmHg. The target DBP is <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• In hypertensive patients with a history of myocardial infarction, beta-blockers and RAS blockers are recommended as part of treatment.</li> <li>• In patients with asymptomatic angina, beta-blockers and/or CCBs are recommended.</li> </ul>
<p>National Institute for Health and Clinical Excellence: <b>Hypertension in adults: diagnosis and management (2019)</b><sup>13</sup></p>	<p><u>Choosing antihypertensive drug treatment (for people with or without type II diabetes)</u></p> <ul style="list-style-type: none"> <li>• Where possible, recommend treatment with drugs taken only once a day.</li> <li>• Prescribe non-proprietary drugs where these are appropriate and minimize cost.</li> <li>• Offer people with isolated systolic hypertension (systolic blood pressure <math>\geq 160</math> mmHg) the same treatment as people with both raised systolic and diastolic blood pressure.</li> <li>• Offer antihypertensive drug treatment to women of child-bearing potential with diagnosed hypertension in line with recommendations in this guideline. For women considering pregnancy or who are pregnant or breastfeeding, manage hypertension in line with the recommendations on Management of pregnancy with chronic hypertension and Breastfeeding in 'Hypertension in pregnancy'.</li> <li>• When choosing antihypertensive drug treatment for adults of black African or African-Caribbean family origin, consider an angiotensin II receptor blocker, in preference to an angiotensin-converting enzyme inhibitor.</li> </ul> <p><u>Step one treatment</u></p> <ul style="list-style-type: none"> <li>• Patients <math>&lt; 55</math> years of age should be offered a step one antihypertensive with an angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB).</li> <li>• Offer an ACE inhibitor or an ARB to adults starting step 1 antihypertensive treatment who have type II diabetes and are of any age or family origin or those aged <math>&lt; 55</math> years but not of black African or African-Caribbean family origin.</li> <li>• If an ACE inhibitor is not tolerated, offer an ARB.</li> <li>• Do not combine an ACE inhibitor with an ARB for the treatment of hypertension.</li> <li>• Offer a calcium channel blocker (CCB) to adults starting step 1 antihypertensive treatment who are <math>&gt; 55</math> years of age and do not have diabetes and are of black African or African-Caribbean family origin and do not have type II diabetes and of any age.</li> <li>• If a CCB is not suitable, for example because of edema or intolerance, or if there is evidence of heart failure or a high risk of heart failure, offer a thiazide-like diuretic.</li> <li>• If diuretic treatment is to be initiated or changed, offer a thiazide-like diuretic, such as indapamide in preference to a conventional thiazide diuretic such as bendroflumethiazide or hydrochlorothiazide.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• For adults with hypertension who are already receiving treatment with bendroflumethiazide or hydrochlorothiazide, who have stable, well-controlled blood pressure, continue with their treatment.</li> </ul> <p><u>Step two treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering next step treatment for hypertension discuss with the person if they are taking their medicine as prescribed and support adherence in line with NICE's guideline on “Medicines adherence: involving patients decisions about prescribed medicines and supporting adherence”.</li> <li>• If hypertension is not controlled with a step one treatment of an ACE inhibitor or ARB, offer choice of one of the following drugs in addition to the step one treatment: a CCB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults taking step one treatment of a CCB, offer the choice of one of the following drugs in addition to the step one treatment: an ACE inhibitor or an ARB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults of black African or African–Caribbean family origin who do not have type 2 diabetes taking step one treatment, consider an ARB, in preference to an ACE inhibitor, in addition to step one treatment.</li> </ul> <p><u>Step three treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering step three treatment, review the person’s medications to ensure they are being taken at the optimal doses and discuss adherence (see recommendation under step two).</li> <li>• If hypertension is not controlled in adults taking step two treatment, offer a combination of an ACE inhibitor or ARB and a CCB and a thiazide-like diuretic.</li> </ul> <p><u>Step four treatment</u></p> <ul style="list-style-type: none"> <li>• If hypertension is not controlled in adults taking the optimal tolerated doses of an ACE inhibitor or an ARB plus a CCB and a thiazide-like diuretic, regard them as having resistant hypertension.</li> <li>• Before considering further treatment for a person with resistant hypertension, confirm elevated clinic blood pressure measurements using ambulatory or home blood pressure recordings, assess for postural hypotension, and discuss adherence.</li> <li>• For people with confirmed resistant hypertension, consider adding a fourth antihypertensive drug as step four treatment or seeking specialist advice.</li> <li>• Consider further diuretic therapy with low-dose spironolactone for adults with resistant hypertension starting step four treatment who have a blood potassium level of 4.5 mmol/l or less. Use particular caution in people with a reduced estimated glomerular filtration rate because they have an increased risk of hyperkalemia.</li> <li>• When using further diuretic therapy for step four treatment of resistant hypertension, monitor blood sodium and potassium and renal function within one month of starting treatment and repeat as needed thereafter.</li> <li>• Consider an alpha-blocker or beta-blocker for adults with resistant hypertension starting step four treatment who have a blood potassium level of more than 4.5 mmol/l.</li> <li>• If blood pressure remains uncontrolled in people with resistant hypertension taking the optimal tolerated doses of four drugs, seek specialist advice.</li> </ul>
<p>International Society on Hypertension in Blacks: <b>Management of High Blood Pressure in</b></p>	<ul style="list-style-type: none"> <li>• To attain and maintain blood pressure (BP) below target levels, multiple antihypertensive drugs will be required in most hypertensive blacks.</li> <li>• Use of two-drug combination therapy when SBP is &gt;15 mm Hg and/or DBP is &gt;10 mm Hg above goal levels is increasingly recommended as first-line therapy.</li> <li>• Two-drug regimens have generally contained a thiazide-type diuretic; however,</li> </ul>

Clinical Guideline	Recommendations
<p><b>Blacks (2010)<sup>14</sup></b></p>	<p>the combination of a calcium channel blocker (CCB) with either an ACE inhibitor or an ARB has been shown equally efficacious in BP lowering but with demonstrated superiority (CCB+ACE) for hard clinical outcomes compared with the same ACE inhibitor plus a thiazide-type diuretic.</p> <ul style="list-style-type: none"> <li>• In secondary prevention patients, the combination therapy should include a drug(s) with the appropriate compelling indications.</li> <li>• Certain classes of antihypertensive medications, specifically diuretics and CCBs, lower BP on average more than <math>\beta</math>-blockers and renin-angiotensin system (RAS) blockers in black patients when used as monotherapies.</li> <li>• In the absence of compelling indications, when BP is near goal levels, monotherapy with a diuretic or a CCB is preferred.</li> <li>• Lifestyle modifications should be initiated in all patients with hypertension, whether or not pharmacotherapy is planned.</li> <li>• ACE inhibitors or ARBs are recommended as alternative monotherapy options in the treatment of hypertension in blacks. The rationale for their lower tier monotherapy recommendation is because they have consistently achieved lesser average reductions in BP relative to that observed with monotherapy using either a diuretic or CCB.</li> </ul>
<p><b>Kidney Disease Improving Clinical Outcomes Group; KDIGO Clinical Practice Guideline for the Management of Blood Pressure in Chronic Kidney Disease (2021)<sup>15</sup></b></p>	<p><u>Blood pressure measurement</u></p> <ul style="list-style-type: none"> <li>• The Work Group recommends standardized office blood pressure (BP) measurement in preference to routine office BP measurements for the management of high BP in adults.</li> <li>• The Work Group suggests that out-of-office BP measurements with ambulatory BP monitoring (ABPM) or home BP monitoring (HBPM) be used to complement standardized office BP readings for the management of high BP.</li> </ul> <p><u>Lifestyle interventions for lowering BP in patients with chronic kidney disease (CKD) not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>• The Work Group suggests targeting a sodium intake &lt;2 grams of sodium per day (or &lt;90 mmol of sodium per day, or &lt;5 grams of sodium chloride per day) in patients with high BP and CKD.</li> <li>• The Work Group suggests that patients with high BP and CKD be advised to undertake moderate-intensity physical activity for a cumulative duration of at least 150 minutes per week, or to a level compatible with their cardiovascular and physical tolerance.</li> </ul> <p><u>BP management in patients with CKD, with or without diabetes, not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>• The Work Group suggests that adults with high BP and CKD be treated with a target systolic BP (SBP) of &lt;120 mmHg, when tolerated, using standardized office BP measurement.</li> <li>• The Work Group recommends starting renin-angiotensin-system inhibitors (RASi) (angiotensin-converting enzyme inhibitor [ACEi] or angiotensin II receptor blocker [ARB]) for people with high BP, CKD, and severely increased albuminuria without diabetes.</li> <li>• The Work Group suggests starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately increased albuminuria without diabetes.</li> <li>• The Work Group recommends starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately-to-severely increased albuminuria with diabetes.</li> <li>• The Work Group recommends avoiding any combination of ACEi, ARB, and direct renin inhibitor (DRI) therapy in patients with CKD, with or without diabetes.</li> </ul> <p><u>BP management in kidney transplant recipients</u></p> <ul style="list-style-type: none"> <li>• Treat adult kidney transplant recipients with high BP to a target BP of &lt;130</li> </ul>

Clinical Guideline	Recommendations
	<p>mmHg systolic and &lt;80 mmHg diastolic using standardized office BP measurement.</p> <ul style="list-style-type: none"> <li>The Work Group recommends that a dihydropyridine calcium channel blocker (CCB) or an ARB be used as the first-line antihypertensive agent in adult kidney transplant recipients.</li> </ul> <p><u>BP management in children with CKD</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests that in children with CKD, 24-hour mean arterial pressure by ABPM should be lowered to &lt;50<sup>th</sup> percentile for age, sex, and height.</li> </ul>
<p>American College of Cardiology/ American Heart Association Task Force: <b>Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults (2017)</b><sup>16</sup></p>	<p><u>Initiation of Blood Pressure (BP) Treatment for Overall Cardiovascular Disease (CVD) Risk</u></p> <ul style="list-style-type: none"> <li>Use of BP-lowering medications is recommended for secondary prevention of recurrent CVD events in patients with clinical CVD and an average systolic blood pressure (SBP) <math>\geq 130</math> mmHg or an average diastolic blood pressure (DBP) of <math>\geq 80</math> mmHg and for primary prevention in adults with an estimated 10-year atherosclerotic cardiovascular disease (ASCVD) risk of <math>\geq 10\%</math> and an average SBP of <math>\geq 130</math> mmHg or an average <math>\geq 80</math> mmHg.</li> <li>Use of BP-lowering medication is recommended for primary prevention of CVD in adults with no history of CVD and with an estimated 10-year ASCVD risk <math>&lt; 10\%</math> and an SBP of <math>\geq 140</math> mmHg or a DBP of <math>\geq 90</math> mmHg.</li> <li>Simultaneous use of an angiotensin converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), and/or renin inhibitor is potentially harmful and is not recommended to treat adults with hypertension.</li> <li>For adults with confirmed hypertension and known CVD or 10-year ASCVD risk of <math>\geq 10\%</math>, a BP target <math>&lt; 130/80</math> mmHg is recommended. For adults with confirmed hypertension without additional markers of increased CVD risk, a BP target <math>&lt; 130/80</math> mmHg may be reasonable.</li> <li>For initiation of antihypertensive drug therapy, first-line agents include thiazide diuretics, calcium channel blockers (CCBs), and ACE inhibitors or ARBs.</li> <li>Initiation of antihypertensive drug therapy with two first-line agents of different classes, either as separate agents or in a fixed-dose combination, is recommended in adults with stage 2 hypertension and an average BP <math>&gt; 20/10</math> mmHg above their BP target.</li> <li>Initiation of antihypertensive drug therapy with a single antihypertensive drug is reasonable in adults with stage 1 hypertension and BP goal <math>&lt; 130/80</math> mmHg with dosage titration and sequential addition of other agents to achieve the BP target.</li> </ul> <p><u>Stable Ischemic Heart Disease (SIHD)</u></p> <ul style="list-style-type: none"> <li>In adults with SIHD and hypertension, a BP target <math>&lt; 130/80</math> is recommended.</li> <li>Adults with SIHD and hypertension (BP <math>\geq 130/80</math> mmHg) should be treated with medications [e.g., guideline-directed medical therapy (GDMT) beta-blockers, ACE inhibitors, or ARBs] for compelling indications [e.g., previous myocardial infarction (MI), stable angina] as first-line therapy, with the addition of other drugs (e.g., dihydropyridine CCBs, thiazide diuretics, and/or mineralocorticoid receptor antagonists) as needed to further control hypertension.</li> <li>In adults with SIHD with angina and persistent uncontrolled hypertension, the addition of dihydropyridine CCBs to GDMT beta-blockers is recommended.</li> <li>In adults who have had a MI or acute coronary syndrome, it is reasonable to continue GDMT beta-blockers beyond three years as long-term therapy for hypertension.</li> <li>Beta-blockers and/or CCBs might be considered to control hypertension in patients with coronary artery disease (CAD) had an MI more than three years ago and have angina.</li> </ul> <p><u>Heart Failure</u></p>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In adults with increased risk of HF, the optimal BP in those with hypertension should be &lt;130 mmHg.</li> <li>• Adults with HF<sub>r</sub>EF and hypertension should be prescribed GDMT titrated to attain a BP &lt;130/80 mmHg.</li> <li>• Non-dihydropyridine CCBs are not recommended in the treatment of hypertension in adults with HF<sub>r</sub>EF.</li> <li>• In adults with HF<sub>p</sub>EF who present with symptoms of volume overload, diuretics should be prescribed to control hypertension.</li> <li>• Adults with HF<sub>p</sub>EF and persistent hypertension after management of volume overload should be prescribed ACE inhibitors or ARBs and beta-blockers titrated to attain SBP &lt;130 mmHg.</li> </ul> <p><u>CKD</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and CKD should be treated to a BP goal &lt;130/80 mmHg.</li> <li>• In adults with hypertension and CKD [stage 3 or higher or stage 1 or 2 with albuminuria (<math>\geq 300</math> mg/d, or <math>\geq 300</math> mg/g albumin-to-creatinine ratio or the equivalent in the first morning void)], treatment with an ACE inhibitor is reasonable to slow kidney disease progression. Treatment with an ARB may be reasonable if an ACE inhibitor is not tolerated.</li> <li>• After kidney transplantation, it is reasonable to treat patients with hypertension to a BP goal &lt;130/80 mmHg and with a CCB on the basis of improved glomerular filtration rate (GFR) and kidney survival.</li> </ul> <p><u>Cerebrovascular Disease</u></p> <ul style="list-style-type: none"> <li>• In adults with intracerebral hemorrhage (ICH) who present with SBP &gt;220 mmHg, it is reasonable to use continuous intravenous (IV) drug infusion and close BP monitoring to lower levels. Immediate lowering of SBP to &lt;140 mmHg in adults with spontaneous ICH who present within six hours of the acute event and have an SBP between 150 mmHg and 220 mmHg is not of benefit to reduce death or severe disability and can be potentially harmful.</li> <li>• Adults with acute ischemic stroke and elevated BP who are eligible for treatment with IV tissue plasminogen activator (tPA) should have their BP slowly lowered to &lt;185/110 mmHg before thrombolytic therapy is initiated.</li> <li>• In adults with an acute ischemic stroke, BP should be &lt;185/110 mmHg before administration of IV tPA and should be maintained below 180/105 mmHg for at least the first 24 hours after initiation drug therapy.</li> <li>• Starting or restarting antihypertensive therapy during hospitalization in patients with BP &gt;140/90 mmHg who are neurologically stable is safe and reasonable to improve long-term BP control, unless contraindicated.</li> <li>• In patient with BP <math>\geq 220/120</math> mmHg who did not receive IV alteplase or endovascular treatment and have no comorbid conditions requiring acute antihypertensive treatment, the benefit of initiating or reinitiating treatment of hypertension within the first 48 to 72 hours is uncertain. It might be reasonable to lower BP by 15% during the first 24 hours after onset of stroke. In patients with BP &lt;220/120 mmHg with the same conditions, initiating or reinitiating treatment of hypertension within the first 48 to 72 hours after an acute ischemic stroke is not effective to prevent death or dependency.</li> <li>• Adults with previously treated stroke or transient ischemic attack should be restarted on antihypertensive treatment after the first few days of the index event to reduce the risk of recurrent stroke and other vascular events. Treatment with a thiazide diuretic, ACE inhibitor, or ARB, or combination treatment consisting of a thiazide diuretic plus ACE inhibitor, is useful.</li> <li>• Adults not previously treated for hypertension who experienced a stroke or transient ischemic attack and have an established BP <math>\geq 140/90</math> mmHg should be</li> </ul>

Clinical Guideline	Recommendations
	<p>prescribed antihypertensive treatment a few days after the index event to reduce the risk of recurrent stroke and other vascular event.</p> <ul style="list-style-type: none"> <li>• For adults who experience a stroke or transient ischemic attack, selection of specific drugs should be individualized on the basis of patient comorbidities and agent pharmacological class.</li> <li>• For adults who experience a stroke or transient ischemic attack, a BP goal &lt;130/80 mmHg may be reasonable.</li> <li>• For adults with a lacunar stroke, a target SBP goal &lt;130 mmHg may be reasonable.</li> <li>• In adults previously untreated for hypertension who experience an ischemic stroke or transient ischemic attack and have an SBP &lt;140 mmHg and a DBP &lt;90 mmHg, the usefulness of initiating antihypertensive treatment is not well established.</li> </ul> <p><u>Peripheral Artery Disease (PAD)</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and PAD should be treated similarly to patients with hypertension without PAD.</li> </ul> <p><u>Diabetes Mellitus (DM)</u></p> <ul style="list-style-type: none"> <li>• In adults with DM and hypertension, antihypertensive drug treatment should be initiated at a BP of <math>\geq 130/80</math> mmHg with a treatment goal &lt;130/80 mmHg.</li> <li>• In adults with DM and hypertension, all first-line classes of antihypertensive agents (i.e., diuretics, ACE inhibitors, ARBs, and CCBs) are useful and effective.</li> <li>• In adults with DM and hypertension, ACE inhibitors or ARBs may be considered in the presence of albuminuria.</li> </ul> <p><u>Atrial Fibrillation, Valvular Heart Disease, and Aortic disease</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension can be useful for prevention of recurrence of AF.</li> <li>• In adults with asymptomatic aortic stenosis, hypertension should be treated with pharmacotherapy, starting at a low dose and gradually titrating upward as needed.</li> <li>• In patients with chronic aortic insufficiency, treatment of systolic hypertension with agents that do not slow the heart rate (i.e., avoid beta-blockers) is reasonable.</li> <li>• Beta-blockers are recommended as the preferred antihypertensive agents in patients with hypertension and thoracic aortic disease.</li> </ul> <p><u>Racial and Ethnic Differences in Treatment</u></p> <ul style="list-style-type: none"> <li>• In black adults with hypertension but without HF or CKD, including those with DM, initial antihypertensive treatment should include a thiazide-type diuretic or CCB. Two or more antihypertensive medications are recommended to achieve a BP target &lt;130/80 mmHg in most adults with hypertension, especially in black adults with hypertension.</li> </ul> <p><u>Pregnancy</u></p> <ul style="list-style-type: none"> <li>• Women with hypertension who become pregnant, or are planning to become pregnant, should be transitioned to methyldopa, nifedipine, and/or labetalol during pregnancy.</li> <li>• Women with hypertension who become pregnant should not be treated with ACE inhibitors, ARBs, or direct renin inhibitors.</li> </ul> <p><u>Older Persons</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension with an SBP treatment goal &lt;130 mmHg is recommended for noninstitutionalized ambulatory community-dwelling adults (<math>\geq 65</math> years of age) with an average SBP of <math>\geq 130</math> mmHg.</li> <li>• For older adults (<math>\geq 65</math> years of age) with hypertension and a higher burden of</li> </ul>

Clinical Guideline	Recommendations
	<p>comorbidity and limited life expectancy, clinical judgment, patient preference, and a team-based approach to assess risk/benefit is reasonable for decisions regarding intensity of BP lowering and choice of antihypertensive drugs.</p> <p><u>Hypertensive Crises</u></p> <ul style="list-style-type: none"> <li>• In adults with a hypertensive emergency, admission to an intensive care unit is recommended for continuous monitoring of BP and target organ damage and for parenteral administration of an appropriate agent.</li> <li>• For adults with a compelling condition (i.e., aortic dissection, severe pre-eclampsia or eclampsia, or pheochromocytoma crisis), SBP should be reduced to &lt;140 mmHg during the first hour and to &lt;120 mmHg in aortic dissection.</li> <li>• For adults without a compelling condition, SBP should be reduced by no more than 25% within the first hours; then, if stable, to 160/100 mmHg within the next two to six hours; and then cautiously to normal during the following 24 to 48 hours.</li> </ul> <p><u>Cognitive Decline and Dementia</u></p> <ul style="list-style-type: none"> <li>• In adults with hypertension, BP lowering is reasonable to prevent cognitive decline and dementia.</li> </ul> <p><u>Patients Undergoing Surgical Procedures</u></p> <ul style="list-style-type: none"> <li>• In patients with hypertension undergoing major surgery who have been on beta-blockers chronically, beta-blockers should be continued.</li> <li>• In patients with hypertension undergoing planned elective major surgery, it is reasonable to continue medical therapy for hypertension until surgery.</li> <li>• In patients with hypertension undergoing major surgery, discontinuation of ACE inhibitors or ARBs perioperatively may be considered.</li> <li>• In patients with planned elective major surgery and SBP <math>\geq</math>180 mmHg or DBP <math>\geq</math>110 mmHg, deferring surgery may be considered.</li> <li>• For patients undergoing surgery, abrupt pre-operative discontinuation of beta-blockers or clonidine is potentially harmful.</li> <li>• Beta-blockers should not be started on the day of surgery in beta-blocker-naïve patients.</li> <li>• Patients with intraoperative hypertension should be managed with IV medications until such time as oral medications can be resumed.</li> </ul>
<p>American Diabetes Association: <b>Standards of Medical Care in Diabetes (2022)</b><sup>17</sup></p>	<p><u>Hypertension/blood pressure control</u></p> <ul style="list-style-type: none"> <li>• Blood pressure should be measured at every routine visit. When possible, patients found to have elevated blood pressure (<math>\geq</math>140/90) should have blood pressure confirmed using multiple readings, including measurements on a separate day, to diagnose hypertension. Patients with blood pressure <math>\geq</math>180/110 and cardiovascular disease could be diagnosed with hypertension at a single visit.</li> <li>• All hypertensive patients with diabetes should monitor their blood pressure at home.</li> <li>• For patients with diabetes and hypertension, with diabetes and hypertension, blood pressure targets should be individualized through a shared decision-making process that addresses cardiovascular risk, potential adverse effects of antihypertensive medications, and patient preferences.</li> <li>• For individuals with diabetes and hypertension at higher cardiovascular risk (existing atherosclerotic cardiovascular disease [ASCVD] or 10-year ASCVD risk <math>\geq</math>15%), a blood pressure target of &lt;130/80 mmHg may be appropriate, if it can be safely attained.</li> <li>• For individuals with diabetes and hypertension at lower risk for cardiovascular disease (10-year atherosclerotic cardiovascular disease risk &lt;15%), treat to blood pressure target of &lt;140/90.</li> <li>• In pregnant patients with diabetes and preexisting hypertension, a blood pressure</li> </ul>

Clinical Guideline	Recommendations
	<p>target of 110 to 135/85 is suggested in the interest of reducing the risk for accelerated maternal hypertension and minimizing impaired fetal growth.</p> <ul style="list-style-type: none"> <li>• For patients with blood pressure &gt;120/80, lifestyle intervention consists of weight loss when indicated, a Dietary Approaches to Stop Hypertension (DASH)-style eating pattern including reducing sodium and increasing potassium intake, moderation of alcohol intake, and increased physical activity.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq</math>140/90 mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of pharmacologic therapy to achieve blood pressure goals.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq</math>160/100 mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of two drugs or a single pill combination of drugs demonstrated to reduce cardiovascular events in patients with diabetes.</li> <li>• Treatment for hypertension should include drug classes demonstrated to reduce cardiovascular events in patients with diabetes (ACE inhibitors, angiotensin receptor blockers, thiazide-like diuretics, or dihydropyridine calcium channel blockers). ACE inhibitors or angiotensin receptor blockers are recommended first-line therapy for hypertension in people with diabetes and coronary artery disease.</li> <li>• Multiple-drug therapy is generally required to achieve blood pressure targets (but not a combination of ACE inhibitors and angiotensin receptor blockers).</li> <li>• An ACE inhibitor or angiotensin receptor blocker, at the maximum tolerated dose indicated for blood pressure treatment, is the recommended first-line treatment for hypertension in patients with diabetes and urinary albumin-to-creatinine ratio <math>\geq</math>300 mg/g creatinine or 30 to 299 mg/g creatinine. If one class is not tolerated, the other should be substituted.</li> <li>• For patients treated with an ACE inhibitor, angiotensin receptor blocker, or diuretic, serum creatinine/estimated glomerular filtration rate and serum potassium levels should be monitored at least annually.</li> <li>• Patients with hypertension who are not meeting blood pressure targets on three classes of antihypertensive medications (including a diuretic) should be considered for mineralocorticoid receptor antagonist therapy.</li> </ul> <p><b>Chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>• At least once a year, assess urinary albumin (e.g., spot urinary albumin-to-creatinine ratio) and estimated glomerular filtration rate in patients with type 1 diabetes with duration of five or more years and in all patients with type 2 diabetes.</li> <li>• Patients with diabetes and urinary albumin <math>\geq</math>300 mg/g creatinine and/ or an estimated glomerular filtration rate 30 to 60 mL/min/1.73 m<sup>2</sup> should be monitored twice annually to guide therapy.</li> <li>• Optimize glucose control to reduce the risk or slow the progression of chronic kidney disease (CKD).</li> <li>• For patients with type 2 diabetes and diabetic kidney disease, use of a sodium-glucose cotransporter 2 inhibitor in patients with an estimated glomerular filtration rate <math>\geq</math>25 mL/min/1.73 m<sup>2</sup> and urinary albumin <math>\geq</math>300 mg/g creatinine is recommended to reduce CKD progression and cardiovascular events.</li> <li>• In patients with type 2 diabetes and CKD, consider use of sodium-glucose cotransporter 2 inhibitors additionally for cardiovascular risk reduction when estimated glomerular filtration rate and urinary albumin creatinine are <math>\geq</math>25 mL/min/1.73 m<sup>2</sup> or <math>\geq</math>300 mg/g, respectively.</li> <li>• In patients with CKD who are at increased risk for cardiovascular events or CKD progression and are unable to use a sodium-glucose cotransporter 2 inhibitor, a nonsteroidal mineralocorticoid receptor antagonist (finerenone) is recommended to reduce CKD progression and cardiovascular events.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>Optimize blood pressure control and reduce blood pressure variability to reduce the risk or slow the progression of CKD.</li> <li>Do not discontinue renin-angiotensin system blockade for minor increases in serum creatinine (<math>\leq 30\%</math>) in the absence of volume depletion.</li> <li>For people with nondialysis-dependent stage 3 or higher CKD, dietary protein intake should be a maximum of 0.8 g/kg body weight per day (the recommended daily allowance). For patients on dialysis, higher levels of dietary protein intake should be considered, since malnutrition is a major problem in some dialysis patients.</li> <li>In nonpregnant patients with diabetes and hypertension, either an ACE inhibitor or an angiotensin receptor blocker is recommended for those with modestly elevated urinary albumin-to-creatinine ratio (30 to 299 mg/g creatinine) and is strongly recommended for those with urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine and/or estimated glomerular filtration rate <math>&lt; 60</math> mL/min/1.73 m<sup>2</sup>.</li> <li>Periodically monitor serum creatinine and potassium levels for the development of increased creatinine or changes in potassium when ACE inhibitors, angiotensin receptor blockers, or diuretics are used.</li> <li>An ACE inhibitor or an angiotensin receptor blocker is not recommended for the primary prevention of CKD in patients with diabetes who have normal blood pressure, normal urinary albumin-to-creatinine ratio (<math>&lt; 30</math> mg/g creatinine), and normal estimated glomerular filtration rate.</li> <li>Patients should be referred for evaluation by a nephrologist if they have an estimated glomerular filtration rate <math>&lt; 30</math> mL/min/1.73 m<sup>2</sup>.</li> <li>Promptly refer to a nephrologist for uncertainty about the etiology of kidney disease, difficult management issues, and rapidly progressing kidney disease.</li> </ul>

### III. Indications

The Food and Drug Administration (FDA)-approved indications for the renin inhibitors are noted in Table 3. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 3. FDA-Approved Indications for the Renin Inhibitors<sup>4,7</sup>**

Indication(s)	Single Entity Agents	Combination Products
	Aliskiren	Aliskiren and HCTZ
<b>Hypertension</b>		
Treatment of hypertension	✓	✓

HCTZ=hydrochlorothiazide

### IV. Pharmacokinetics

The pharmacokinetic parameters of the renin inhibitors are listed in Table 4.

**Table 4. Pharmacokinetic Parameters of the Renin Inhibitors<sup>5</sup>**

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life (hours)
<b>Single Entity Agents</b>					
Aliskiren	2.5	47 to 51	Liver, minor (%) not reported)	Feces (91) Renal (<1)	40

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life (hours)
<b>Combination Products</b>					
Aliskiren and HCTZ	2.5/50 to 75	47 to 51/ 40 to 68	Liver, minor (% not reported)/ Not reported	Feces (91) Renal (<1)/ Renal (>95)	40/6 to 15

HCTZ=hydrochlorothiazide

## V. Drug Interactions

Major drug interactions with the renin inhibitors are listed in Table 5.

**Table 5. Major Drug Interactions with the Renin Inhibitors<sup>5</sup>**

Generic Name(s)	Interaction	Mechanism
Renin Inhibitors (aliskiren)	ACE inhibitors	Aliskiren is contraindicated in patients with diabetes who are receiving ARBs or ACEIs because of the increased risk of renal impairment, hyperkalemia, and hypotension. In general, avoid combined use of aliskiren with ACE inhibitors or ARBs, particularly in patients with creatinine clearance (CrCl) <60 mL/min.
Renin Inhibitors (aliskiren)	ARBs	Aliskiren is contraindicated in patients with diabetes who are receiving ARBs or ACEIs because of the increased risk of renal impairment, hyperkalemia, and hypotension. In general, avoid combined use of aliskiren with ACE inhibitors or ARBs, particularly in patients with CrCl <60 mL/min.
Renin Inhibitors (aliskiren)	Azole antifungals	Increased absorption of aliskiren resulting from inhibition of P-gp expression by certain azole antifungal agents may occur. In addition, azole antifungal agents may inhibit aliskiren metabolism (CYP3A4).
Renin Inhibitors (aliskiren)	Cyclosporine	Concurrent use of aliskiren and cyclosporine may result in increased aliskiren exposure and plasma concentrations.
Thiazide diuretics (HCTZ)	Dofetilide	Thiazide diuretics may induce hypokalemia and increase the risk of torsades de pointes.
Thiazide diuretics (HCTZ)	Lithium	Decreased lithium clearance may occur with thiazide use, which may lead to increased serum lithium levels and possibly lithium toxicity.
Thiazide diuretics (HCTZ)	Diazoxide	The combination of diazoxide with a thiazide diuretic may lead to hyperglycemia, hyperuricemia, and hypotension.
Thiazide diuretics (HCTZ)	Digitalis glycosides	Thiazide diuretics may induce electrolyte disturbances which may predispose patients to digitalis-induced arrhythmias.

ACE inhibitor=angiotensin converting enzyme inhibitor, ARB=angiotensin II receptor antagonist

## VI. Adverse Drug Events

The most common adverse drug events reported with the renin inhibitors are listed in Table 6. The boxed warning for aliskiren-containing products is listed in Table 7.

**Table 7. Boxed Warning for Aliskiren Products<sup>4</sup>**

<b>WARNING</b>
When pregnancy is detected, discontinue aliskiren as soon as possible. Drugs that act directly on the renin-angiotensin system can cause injury and death to the developing fetus.

## VII. Dosing and Administration

The usual dosing regimens for the renin inhibitors are listed in Table 8.

**Table 8. Usual Dosing Regimens for the Renin Inhibitors<sup>4-7</sup>**

<b>Generic Name(s)</b>	<b>Usual Adult Dose</b>	<b>Usual Pediatric Dose</b>	<b>Availability</b>
<b>Single Entity Agents</b>			
Aliskiren	<u>Hypertension:</u> Tablet: initial, 150 mg once daily; maintenance, titrate as needed; maximum, 300 mg/day	<u>Hypertension in pediatric patients 6 to 17 years of age:</u> Tablet: 20 to 50 kg, initial, 75 mg once daily; maximum, 150 mg daily; ≥50 kg, follow adult dosing	Tablet: 150 mg 300 mg
<b>Combination Products</b>			
Aliskiren and HCTZ	<u>Hypertension:</u> Tablet: initial, 150-12.5 mg once daily; maximum, 300-25 mg/day	Safety and efficacy in children have not been established.	Tablet: 150-12.5 mg 150-25 mg 300-12.5 mg 300-25 mg

HCTZ=hydrochlorothiazide

## VIII. Effectiveness

Clinical studies evaluating the safety and efficacy of the renin inhibitors are summarized in Table 9.

**Table 9. Comparative Clinical Trials with the Renin Inhibitors**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<b>Cardiovascular Risk Reduction</b>				
Parving et al. <sup>18</sup> (2012) ALTITUDE  Aliskiren  vs  placebo  Both in addition to standard treatment	DB, PC, RCT  Patients ≥35 years of age with type 2 diabetes and evidence of microalbuminuria, macroalbuminuria, or cardiovascular disease	N=8,561  Median of 32.9 months	Primary: Composite of death from cardiovascular causes or the first occurrence of cardiac arrest with resuscitation; nonfatal MI; nonfatal stroke; unplanned hospitalization for HF; end-stage renal disease, death attributable to kidney failure, or the need for renal- replacement therapy with no dialysis or transplantation available or initiated; or a serum creatinine value that was at least double the baseline value and that exceeded the upper limit of the normal range  Secondary: Composite of cardiovascular	The independent data and safety monitoring committee recommended termination of the study medication, on the basis of their assessment that the excess risk of adverse events in the aliskiren group could not be offset by a reduction in major cardiovascular and renal events.  Primary: The primary outcome occurred in 783 participants in the aliskiren group (18.3%) and 732 in the placebo group (17.1%). The hazard ratio for this outcome in the aliskiren group as compared with the placebo group was 1.08 (95% CI, 0.98 to 1.20; P=0.12).  Secondary: The secondary cardiovascular composite outcome occurred in 590 participants in the aliskiren group (13.8%) and 539 in the placebo group (12.6%); the HR in the aliskiren group was 1.11 (95% CI, 0.99 to 1.25; P=0.09).  The secondary renal composite outcome occurred in 257 participants in the aliskiren group (6.0%) and 251 in the placebo group (5.9%); the HR in the aliskiren group was 1.03 (95% CI, 0.87 to 1.23; P=0.74).  The number of deaths from any cause did not differ significantly between the study groups.

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
			components and of renal components of the primary composite end point	
<p>McMurray et al.<sup>19</sup> (2016) ATMOSPHERE</p> <p>Enalapril 5 or 10 mg BID</p> <p>vs</p> <p>aliskiren 150 mg QD</p> <p>vs</p> <p>combination of aliskiren 150 mg QD and enalapril 5 or 10 mg BID</p>	<p>DB, DD, RCT</p> <p>Patients with CHF (NYHA class II to IV) and EF <math>\leq</math>35% receiving stable doses of an ACE inhibitor (equivalent to at least 10 mg of enalapril daily) and of a <math>\beta</math>-blocker at the time of enrollment</p>	<p>N=7,016</p> <p>Median of 36.6 months</p>	<p>Primary: Composite of death from cardiovascular causes or hospitalization for heart failure</p> <p>Secondary: Change from baseline to 12 months in the Kansas City Cardiomyopathy Questionnaire (KCCQ) clinical summary score</p>	<p>Primary: Overall, the primary outcome occurred in 770 patients (32.9%) in the combination-therapy group (11.7 events per 100 person-years), in 791 patients (33.8%) in the aliskiren group (12.1 events per 100 person-years), and in 808 patients (34.6%) in the enalapril group (12.4 events per 100 person-years). The hazard ratio in the combination-therapy group, as compared with the enalapril group, was 0.93 (95% CI, 0.85 to 1.03; P=0.17); the hazard ratio in the aliskiren group, as compared with the enalapril group, was 0.99 (95% CI, 0.90 to 1.10; P=0.91 for superiority). Although the noninferiority margin of 1.104 was met with the use of the 95% confidence interval, the one-sided P value of 0.0184 did not fulfill the prespecified requirement of a P value of 0.0123 or less. A sensitivity analysis that included only patients who received the assigned trial regimen gave consistent results, as did an analysis in which data that were collected after regulatory censoring were included.</p> <p>Secondary: There were no significant between-group differences in the secondary outcome. The exploratory composite renal outcome (the composite of death from renal causes, end-stage renal disease, or doubling of the serum creatinine level) occurred significantly more frequently in the combination-therapy group than in the enalapril group.</p>
<b>Hypertension</b>				
<p>Tocci et al.<sup>20</sup> (abstract) 2012</p> <p>Aliskiren 150 to 300 mg/day</p>	<p>MC, OL, OS, PRO</p> <p>Patient with HTN not adequately controlled on <math>\geq</math>2 other antihypertensive agents</p>	<p>N=1,186</p> <p>12 months</p>	<p>Primary: Efficacy, safety</p> <p>Secondary: Not reported</p>	<p>Primary: SBP and DBP was 141.1/82.4, 134.9/79.8, and 133.6/78.9 mmHg at one, six and 12 month follow-up visits, respectively (P&lt;0.0001 vs baseline for all comparisons). These effects were consistent in all predefined subgroups, including those with left ventricular hypertrophy, renal disease, diabetes mellitus, CAD, or cerebrovascular disease.</p> <p>Reduced levels of microalbuminuria were reported, without affecting other renal and electrolyte parameters.</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				Secondary: Not reported
Oh et al. <sup>21</sup> (2007)  Aliskiren 150, 300, or 600 mg QD  vs  placebo	DB, MC, PC, PG, RCT  Men and women ≥18 years (mean age 53 years) with mild-to-moderate essential HTN (DBP ≥95 and <110 mm Hg)	N=672  8 weeks	Primary: Change in mean sitting DBP  Secondary: Change in mean sitting SBP, 24-hour ABPM, proportion achieving a successful treatment response (DBP <90 mm Hg or ≥10 mm Hg pressure reduction from baseline) or blood pressure control (<140/90 mm Hg), plasma renin activity and concentration, safety and tolerability	Primary: All three doses investigated provided significantly greater reductions in mean sitting DBP from baseline compared to placebo (P<0.0001 for all). The mean sitting DBP reductions were 10.3 mm Hg with 150 mg, 11.1 mm Hg with 300 mg and 12.5 mm Hg with 600 mg compared to 4.9 mm Hg with placebo.  Secondary: All three doses provided significantly greater reductions in mean sitting SBP from baseline compared to placebo (P<0.0001 for all). The mean sitting SBP reductions were 13.0 mm Hg with 150 mg, 14.7 mm Hg with 300 mg and 15.8 mm Hg with 600 mg compared to 3.8 mm Hg with placebo.  Reduction in the 24-hour ABPM was significantly greater in all doses of aliskiren compared to placebo (n=216; P<0.0001 for all). Reductions in mean ambulatory DBP and SBP were consistent across the 24-hour dosing interval with all aliskiren doses.  The proportion of patients achieving a successful treatment response was 59.3% with aliskiren 150 mg, 63.3% with 300 mg and 69.3% with 600 mg compared to 36.2% with placebo (P<0.0001 for all).  The proportion of patients achieving blood pressure control was 35.9% with 150 mg, 41.6% with 300 mg and 46.4% with 600 mg compared to 20.3% with placebo (P<0.0001 for all).  Plasma renin activity decreased 79.5% with 150 mg, 81.1% with 300 mg and 75.0% with 600 mg compared to an increase of 19.5% with placebo. Aliskiren resulted in dose-dependent increases from baseline in renin concentrations (51.5%, 101.6%, and 228.5% for 150, 300 and 600 mg, respectively). Renin concentrations were almost unchanged with placebo.
Kushiro et al. <sup>22</sup> (2006)	DB, MC, PC, PG, RCT	N=455  8 weeks	Primary: Change in mean sitting DBP	Primary: All three aliskiren doses provided significantly greater reductions in mean sitting DBP from baseline compared to placebo. The placebo-corrected

<p>Aliskiren 75, 150, or 300 mg QD</p> <p>vs</p> <p>placebo</p>	<p>Japanese men and women between the ages of 20 and 80 years with essential HTN (mean sitting DBP of <math>\geq 90</math> mm Hg and <math>&lt; 110</math> mm Hg during the run-in period and <math>\geq 95</math> mm Hg and <math>&lt; 110</math> mm Hg at baseline)</p>		<p>Secondary: Change in mean trough sitting SBP, proportion of patients responding to treatment (mean sitting DBP <math>&lt; 90</math> mm Hg and/or <math>\geq 10</math> mm Hg decrease in mean sitting DBP from baseline), dose-response relationship, safety</p>	<p>reductions in mean sitting DBP were 4.0 mm Hg with 75 mg aliskiren, 4.5 mm Hg with 150 mg and 7.5 mm Hg with 300 mg (<math>P &lt; 0.0005</math> for all).</p> <p>Secondary: The mean sitting SBP reductions were significantly lower with all aliskiren doses when compared to placebo. The placebo-corrected reductions in mean sitting SBP were 5.7 mm Hg with 75 mg aliskiren, 5.9 mm Hg with 150 mg and 11.2 mm Hg with 300 mg (<math>P &lt; 0.001</math> for all).</p> <p>The proportion of responders at study end point was 47.8% with aliskiren 75 mg, 48.2% with 150 mg and 63.7% with 300 mg compared to 27.8% with placebo (<math>P &lt; 0.005</math> for all).</p> <p>Dose-response analysis showed that the relationship between reductions in mean sitting DBP and SBP and aliskiren dose was almost linear. However, further analyses revealed that a pattern of similar reductions with aliskiren 75 and 150 mg and greater reductions with aliskiren 300 mg was a better fit for both mean sitting DBP and SBP.</p> <p>The incidence of drug-related adverse events was comparable between aliskiren (53 to 55%) and placebo (50%). There was no evidence of a dose-dependent increase in the incidence of all-causality adverse events at the aliskiren doses evaluated in this study.</p>
<p>Musini et al.<sup>23</sup> (2009)</p> <p>Aliskiren (variable doses)</p> <p>vs</p> <p>placebo</p>	<p>MA</p> <p>Patients <math>\geq 18</math> years of age with mild to moderate essential HTN (defined as mean sitting DBP <math>\leq 95</math> mm Hg and <math>\leq 110</math> mm Hg at baseline)</p>	<p>N=3,694 (6 trials)</p> <p>8 weeks</p>	<p>Primary: Changes in dose-related SBP and DBP</p> <p>Secondary: Variability of blood pressure, pulse pressure, heart rate, withdrawals due to adverse effects, and rates of specific adverse effects</p>	<p>Primary: Aliskiren monotherapy was more effective than placebo in lowering mean sitting SBP. The additional magnitude of blood pressure lowering minus the placebo effect: aliskiren 75 mg vs placebo -2.94 (95% CI, -4.56 to -1.31); aliskiren 150 mg vs placebo -5.45 (95% CI, -6.46 to -4.43); aliskiren 300 mg vs placebo -8.66 (95% CI, -9.68 to 7.64); aliskiren 600 mg vs placebo -11.36 (95% CI, -13.53 to -9.19).</p> <p>Aliskiren monotherapy was more effective than placebo in lowering mean sitting DBP. The additional magnitude of blood pressure lowering minus the placebo effect: aliskiren 75 mg vs placebo -2.29 (95% CI, -3.31 to -1.26); aliskiren 150 mg vs placebo -3.00 (95% CI, -3.65 to -2.34); aliskiren 300 mg vs placebo -4.97 (95% CI, -5.62 to -4.31); aliskiren 600 mg vs placebo -6.57 (95% CI, -7.92 to -5.23).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>Secondary: No trials reported on pulse pressure at baseline or end point. Two trials recorded baseline heart rate, but no data were provided at week eight.</p> <p>There were no significant differences in withdrawals between placebo and aliskiren at any dose. The relative risk for aliskiren 75 mg vs placebo was 0.97 (95% CI, 0.49 to 1.89); for aliskiren 150 mg vs placebo was 1.01 (95% CI, 0.61 to 1.69); for aliskiren 300 mg vs placebo was 0.91 (95% CI, 0.57 to 1.47) and for aliskiren 600 mg vs placebo was 0.63 (9% CI, 0.21 to 1.89).</p> <p>One trial reported on the incidence of dry cough: placebo (1.1%); aliskiren 75 mg (1.1%); aliskiren 150 mg (2.8%); aliskiren 300 mg (0.6%). No trials reported angioedema.</p> <p>The blood pressure lowering efficacy of aliskiren 150 mg vs 75 mg, as well as aliskiren 600 mg vs 300 mg was not significantly different. Aliskiren 300 mg significantly lowered both SBP and DBP as compared to 150 mg (SBP: -2.97; 95% CI, -3.99 to -1.95; DBP: -1.66; 95% CI, -2.32 to -1.0).</p>
<p>Braun-Dullaes et al.<sup>24</sup> (2012)</p> <p>Aliskiren 150 mg QD, up titrated to 300 mg QD</p> <p>vs</p> <p>placebo</p> <p>All patients received amlodipine 5 mg/day, up titrated</p>	<p>DB, MC, RCT</p> <p>Patients with HTN (mean sitting SBP <math>\geq</math>160 to &lt;200 mm Hg)</p>	<p>N=485</p> <p>8 weeks</p>	<p>Primary: Change in baseline mean sitting SBP and DBP, blood pressure control rate (&lt;140/90 mm Hg)</p> <p>Secondary: Safety</p>	<p>Primary: After eight weeks, add-on treatment with aliskiren resulted in significantly greater reductions in mean sitting SBP and DBP compared to placebo (-37.7/-16.1 vs -30.6/-12.3 mm Hg; P&lt;0.0001).</p> <p>After eight weeks, significantly more patients receiving aliskiren add-on therapy achieved blood pressure control compared to placebo (67.0 vs 49.1%; P=0.0001).</p> <p>Secondary: The overall incidence of adverse events was similar between both treatments. The most commonly reported adverse event was peripheral edema, with a higher incidence occurring in patients receiving placebo (18.3 vs 14.4%).</p>

vs  aliskiren 300 mg QD (existing therapy)				
Blumenstein et al. <sup>36</sup> (2009)  Aliskiren and HCTZ 300-25 mg QD (fixed-dose combination product)  vs  aliskiren and HCTZ 150-25 mg QD (fixed-dose combination product)  vs  HCTZ 25 mg (existing therapy)	DB, MC, RCT  Patients with HTN and an inadequate response to HCTZ (mean sitting DBP >90 and ≤110 mm Hg following 4 weeks of HCTZ 25 mg)	N=722  8 weeks	Primary: Changes in mean sitting SBP/DBP, proportion of patients achieving blood pressure control (mean sitting blood pressure <140/90 mm Hg), and blood pressure response rates (msDBP <90 mm Hg or a ≥10 mm Hg decrease from baseline)  Secondary: Not reported	Primary: The mean reductions in mean sitting SBP/DBP from baseline with aliskiren and HCTZ 300-25 and 150-25 mg were significantly greater compared to those achieved with HCTZ monotherapy (P<0.001 for all).  Rates of blood pressure control were significantly higher with aliskiren and HCTZ 300-25 and 150-25 mg compared to HCTZ monotherapy (P<0.001 for both).  Aliskiren and HCTZ 300-25 mg provided significantly greater reductions in mean sitting SBP/DBP and rates of blood pressure control compared to aliskiren and HCTZ 150-25 mg dose (P<0.05 for all).  Blood pressure response rates were significantly higher with aliskiren and HCTZ 300-25mg (78.5%) and aliskiren and HCTZ 150-25 mg (67.4%) compared to HCTZ monotherapy (47.1%; P<0.001 for both comparisons).  All treatments were generally well-tolerated and the proportion of patients experiencing adverse events was similar across treatment groups. The majority of adverse events were mild and transient. Adverse events reported in >2% of patients were nasopharyngitis, dizziness, back pain, and vertigo.  The proportion of patients with serum potassium <3.5 mmol/L was lower with aliskiren and HCTZ (1.3 to 2.2%) compared to HCTZ monotherapy (3.4%). Hyperkalemia (serum potassium >5.5 mmol/L) was observed in only one patient receiving aliskiren and HCTZ and two patients in the HCTZ monotherapy group. No patient had increases in serum creatinine above the pre-specified clinically significant threshold.  Secondary: Not reported

Ferdinand et al. <sup>38</sup> (abstract) (2012)  Aliskiren and amlodipine and HCTZ 300-10-25 mg /day (fixed-dose combination product)  vs  aliskiren and amlodipine 150-5 mg/day (fixed-dose combination product)	Subgroup analysis  Patients with HTN and any of the following: diabetes, cardiometabolic syndrome, obesity, or black patients	N=not reported  8 weeks	Primary: Change in baseline mean sitting SBP  Secondary: Not reported	Primary: LSM reductions in mean sitting SBP, across all subgroups ranged from 35 to 37 mm Hg with aliskiren and amlodipine and HCTZ compared to 28 to 30 mm Hg with aliskiren and amlodipine (P<0.01).  Secondary: Not reported
Gradman et al. <sup>39</sup> (2005)  Aliskiren 150 to 600 mg QD  vs  irbesartan 150 mg QD  vs  placebo	DB, MC, PC, PG, RCT  Men and women, age 18 years or older, with mild-to-moderate essential HTN (mean sitting DBP ≥95 mm Hg and <110 mm Hg)	N=652  8 weeks	Primary: Change in mean sitting DBP and SBP  Secondary: Proportion of patients achieving blood pressure control (<140/90 mm Hg), safety	Primary: Decreases in mean sitting DBP at eight weeks were significantly greater with all doses of aliskiren compared to placebo (P<0.001). The least-squares mean reductions in trough DBP for aliskiren 150, 300, and 600 mg were 9.3, 11.8, and 11.5 mm Hg, respectively, vs 6.3 mm Hg for placebo.  Decreases in mean sitting SBP at eight weeks were significantly greater with all doses of aliskiren compared to placebo (P<0.001). The least-squares mean reductions in trough SBP for aliskiren 150, 300, and 600 mg were 11.4, 15.8, and 15.7 mm Hg, respectively, vs 5.3 mm Hg for placebo.  The antihypertensive effect of aliskiren 150 mg was comparable to irbesartan 150 mg with reductions of 8.9 and 12.5 mm Hg for mean sitting DBP and SBP, respectively. Aliskiren 300 and 600 mg produced significantly greater mean sitting DBP reductions than irbesartan 150 mg

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>(P&lt;0.05). While the reductions in mean sitting SBP were greater with aliskiren 300 and 600 mg than irbesartan 150 mg, these differences were not statistically significant).</p> <p>Secondary: The percentage of patients achieving blood pressure control was significantly greater with all doses of aliskiren (37.8%-150 mg, 50.0%-300 mg, 45.7%-600 mg) and irbesartan (33.8%) compared to placebo (20.8%; P&lt;0.05). More patients on aliskiren 300 and 600 mg achieved blood pressure control compared to irbesartan (P&lt;0.05).</p> <p>Drug-related adverse events for both aliskiren and irbesartan were comparable to placebo and the most commonly reported adverse events were headache, dizziness, and diarrhea. The number of patients discontinuing therapy was similar in all groups.</p>
<p>O'Brien et al.<sup>40</sup> (2007)</p> <p>Aliskiren 150 mg QD for 3 weeks, then HCTZ 25 mg QD was added for an additional 3 weeks (if ABPM remained <math>\geq</math>135/85 mm Hg)</p> <p>vs</p> <p>irbesartan 150 mg QD for 3 weeks, then aliskiren 75 mg QD added for 3 weeks, then aliskiren 150 mg QD added for 3 weeks</p>	<p>3 OL studies</p> <p>Men and women 18 to 80 years with ambulatory SBP <math>\geq</math>140 and <math>\leq</math>180 mm Hg without treatment</p>	<p>N=67</p> <p>6 to 9 weeks</p>	<p>Primary: Change in daytime systolic ABPM with combination therapy compared to monotherapy</p> <p>Secondary: Change in daytime diastolic ABPM, nighttime systolic and diastolic ABPM, daytime and nighttime heart rates, plasma renin activity</p>	<p>Primary: Aliskiren coadministered with HCTZ (P=0.0007) or ramipril (P=0.03) led to significantly greater reductions in daytime systolic ABPM compared to monotherapy. There was a trend for a reduction in daytime systolic ABPM with the addition of aliskiren to irbesartan; however, this trend was not statistically significant.</p> <p>Secondary: Aliskiren plus HCTZ significantly lowered daytime diastolic ABPM compared to aliskiren monotherapy (P=0.0006). Changes in nighttime systolic and diastolic ABPM followed similar trends but did not achieve statistical significance (P=0.06 and P=0.09, respectively). No changes in heart rate were observed with either aliskiren regimen.</p> <p>Aliskiren added to irbesartan did not significantly change diastolic ABPM compared to irbesartan monotherapy; however, nighttime systolic and diastolic ABPM were significantly reduced (P&lt;0.05 for all). No changes in heart rate were observed with either irbesartan regimen.</p> <p>Mean diastolic ABPM was significantly decreased with the addition of aliskiren 150 mg (P&lt;0.05) but not aliskiren 75 mg to ramipril monotherapy. Both aliskiren doses significantly decreased nighttime systolic and diastolic</p>

<p>Bakris et al.<sup>48</sup> (2013) VIVID</p> <p>Therapy with aliskiren/valsartan 150/160 mg titrated to 300/320</p>	<p>AC, DB, RCT</p> <p>Hypertensive adults with type 2 diabetes and stage 1 or 2 chronic kidney disease (CKD)</p>	<p>N=1143</p> <p>8 weeks</p>	<p>Primary: ABP</p> <p>Secondary: Safety</p>	<p>Primary:</p> <p>Both treatments produced significant reductions from baseline to week 8 in all ABPM measures (P&lt;0.0001). The addition of aliskiren to valsartan was associated with an incremental benefit of 4.0 mm Hg of lowering in 24-hour mean ambulatory (ma)SBP and 2.4 mm Hg of lowering in 24-hour maDBP (both P&lt;0.001).</p> <p>Secondary:</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
mg vs valsartan monotherapy 160 mg titrated to 320 mg				Adverse events were experienced by 202 participants (35.2%) in the combination aliskiren/valsartan group and by 182 participants (32.2%) in the valsartan group.
Pool et al. <sup>49</sup> (2007)  Aliskiren 75 to 300 mg QD  vs  valsartan 80 to 320 mg  vs  aliskiren 75 to 300 mg and valsartan 80 to 320 mg  vs  valsartan and HCTZ 160-12.5 mg QD (fixed-dose combination)  vs  placebo	DB, MC, PC, PG, RCT  Men and women ≥18 years with mild-to-moderate essential HTN (mean sitting DBP ≥95 mm Hg after a 3- to 4-week single-blind placebo run-in period)	N=1,123  8 weeks	Primary: Change in mean sitting DBP  Secondary: Change in mean sitting SBP, safety	Primary: Aliskiren 300 mg significantly (P<0.0001) lowered mean sitting DBP compared to placebo. Reductions in mean sitting DBP for aliskiren 75 and 150 mg compared to placebo failed to reach statistical significance (P=0.052 and P=0.051, respectively).  Secondary: Aliskiren 300 mg significantly (P<0.0001) lowered mean sitting SBP compared to placebo.  A statistically significant linear dose relationship was observed for the effect of aliskiren (75 to 300 mg) on mean sitting DBP (P=0.0002) and mean sitting SBP (P=0.0005). The effects of aliskiren monotherapy on mean sitting DBP and SBP across the 75 to 300 mg dose range were similar to the effects of valsartan 80 to 320 mg.  Coadministration of aliskiren and valsartan produced a greater antihypertensive effect than either drug alone. Reductions in mean sitting DBP and SBP obtained with aliskiren 150 mg plus valsartan 160 mg and aliskiren 300 mg plus valsartan 320 mg were not significantly different from those observed with valsartan 160 mg plus HCTZ 12.5 mg. Responder rates were significantly greater than placebo for all 3 aliskiren monotherapy groups and for all aliskiren plus valsartan combinations. The proportion of responders with aliskiren 75 mg plus valsartan 80 mg was significantly greater than either component monotherapy (P<0.05). There was no significant difference between the proportion of responders to aliskiren 150 mg plus valsartan 160 mg or aliskiren 300 mg plus valsartan 320 mg compared to valsartan 160 mg plus HCTZ 12.5 mg.

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>Control rates were higher with aliskiren 300 mg compared to placebo and with valsartan 160 mg plus HCTZ 12.5 mg compared to aliskiren 150 mg plus valsartan 160 mg, but there were no significant differences between aliskiren plus valsartan combinations and the respective monotherapies.</p> <p>Aliskiren and valsartan were generally well tolerated either as monotherapy or in combination. The overall incidence of adverse events and rate of discontinuations because of adverse events were similar to placebo in all active treatment groups.</p>
<p>Geiger et al.<sup>50</sup> (2009)</p> <p>Aliskiren 150 to 300 mg QD, added to existing HCTZ therapy</p> <p>vs</p> <p>valsartan 160 to 320 mg QD, added to existing HCTZ therapy</p> <p>vs</p> <p>aliskiren 150 to 300 mg and valsartan 160 to 320 mg QD, added to existing HCTZ therapy</p> <p>vs</p> <p>HCTZ 25 mg QD</p>	<p>AC, DB, RCT</p> <p>Patients ≥18 years of age with mild to moderate essential HTN who were taking HCTZ for 4 weeks with a DBP ≥95 mm Hg</p>	<p>N=641</p> <p>8 weeks</p>	<p>Primary: Change in DBP at week 8</p> <p>Secondary: Change SBP at week 8, change in DBP and SBP at week 4, proportion of patients achieving blood pressure control (SBP/DBP &lt;140/90 mm Hg), change in plasma renin activity, plasma renin concentration</p>	<p>Primary: After eight weeks of therapy, the triple therapy showed significantly greater reductions in SBP and DBP compared to the other groups. The additional SBP and DBP reductions were 7 and 5 mm Hg, respectively compared to aliskiren and HCTZ (P&lt;0.0001), 3 and 2 mm Hg compared to valsartan and HCTZ (P&lt;0.01), and 15 and 10 mm Hg compared to HCTZ monotherapy (P&lt;0.001).</p> <p>Aliskiren and HCTZ and valsartan and HCTZ combination therapies were more effective compared to HCTZ monotherapy. Valsartan and HCTZ was more effective than aliskiren and HCTZ. SBP and DBP were reduced by 15 and 11 mm Hg, respectively in the aliskiren and HCTZ group. SBP and DBP were reduced by 18 and 14 mm Hg, respectively, in the valsartan and HCTZ group.</p> <p>Secondary: Blood pressure control rate was significantly higher with triple therapy compared to aliskiren and HCTZ (40.9%, P&lt;0.001), valsartan and HCTZ (48.7%, P&lt;0.001), and HCTZ monotherapy (20.5%, P&lt;0.001).</p> <p>At week four, a significantly greater blood pressure control rate was observed for the triple therapy group at lower doses (150-160-25 mg) compared to the respective doses of the other groups: aliskiren and valsartan and HCTZ (300-320-25 mg) group (56%) compared to aliskiren and HCTZ (36.6%, P&lt;0.05), valsartan and HCTZ (42.2%, P&lt;0.05), and HCTZ monotherapy (19.9%, P&lt;0.01).</p> <p>At week eight, plasma renin concentration was unchanged in the HCTZ</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>group, but was significantly increased in other groups. A significant decrease in plasma renin activity from baseline was observed in the aliskiren and HCTZ group (P&lt;0.001) and a significant increase was observed in the valsartan and HCTZ (P&lt;0.001). In the HCTZ and triple therapy groups, there was no change in plasma renin activity (both P&gt;0.75).</p>
<p>Dietz et al.<sup>51</sup> (2008)</p> <p>Aliskiren 150 to 300 mg QD</p> <p>vs</p> <p>atenolol 50 to 100 mg QD</p> <p>vs</p> <p>aliskiren 150 to 300 mg and atenolol 50 to 100 mg QD</p>	<p>RCT, DB, MC</p> <p>Patients ≥18 years of age with HTN (mean sitting DBP ≥95 and &lt;110 mm Hg)</p>	<p>N=694</p> <p>12 weeks</p>	<p>Primary: Changes in mean sitting SBP and mean sitting DBP, rates of blood pressure control (&lt;140/90 mm Hg), pulse pressure and pulse rate, plasma renin concentration, plasma renin activity</p> <p>Secondary: Not reported</p>	<p>Primary: Treatment with aliskiren and atenolol combination therapy led to a significantly greater reduction in mean sitting SBP by 17.3 mm Hg compared to aliskiren monotherapy (difference, -2.9 mm Hg; P=0.039) or atenolol monotherapy (difference, -3.0 mm Hg; P=0.034). There was no difference between mean sitting SBP reductions with aliskiren and atenolol monotherapy (difference, -0.1 mm Hg; P=0.954).</p> <p>Treatment with aliskiren and atenolol combination therapy led to a significantly greater reduction in mean sitting DBP by 14.1 mm Hg compared to aliskiren monotherapy (difference, -2.9 mm Hg; P&lt;0.001), but not atenolol monotherapy (difference, -0.5 mm Hg; P=0.545). Reductions in mean sitting DBP with atenolol were larger compared to those observed with aliskiren (difference, 2.4 mm Hg; P=0.003).</p> <p>Rates of blood pressure control were higher with aliskiren and atenolol combination therapy (51.3%) compared to aliskiren monotherapy (36.1%, P&lt;0.001) or atenolol monotherapy (42.2%, P=0.009). There was no significant difference in blood pressure control rates between aliskiren and atenolol monotherapy (P=0.388).</p> <p>Mean pulse pressure was reduced by 3.0 mm Hg with aliskiren and atenolol combination therapy and aliskiren monotherapy. Atenolol monotherapy did not affect pulse pressure. Aliskiren monotherapy did not affect pulse rate. Significant mean reductions in pulse rate of &gt;10 bpm were observed with atenolol monotherapy and the aliskiren and atenolol combination (P&lt;0.001 vs aliskiren monotherapy for both).</p> <p>Aliskiren monotherapy increased plasma renin concentration by 241% and aliskiren/atenolol increased plasma renin concentration by 85% (P=0.010 vs aliskiren). Atenolol monotherapy decreased plasma renin concentration by 24% (P&lt;0.001 vs aliskiren and aliskiren/atenolol). Aliskiren, atenolol</p>

300 mg QD  vs  placebo				combination (P=0.001 and P <0.001, respectively) compared to placebo. There was no significant change in 24-hr blood pressure with irbesartan compared to combination therapy.  GFR was significantly reduced 4.6 mL/min/1.73 m <sup>2</sup> with aliskiren (P=0.037), 8.0 mL/min/1.73 m <sup>2</sup> with irbesartan (P<0.001), and 11.7 mL/min/1.73 m <sup>2</sup> with the combination (P<0.001) compared to placebo.
Parving et al. <sup>56</sup> (2008) AVOID  Aliskiren 150 mg QD for 3 months, followed by 300 mg QD for 3 months  vs  placebo  Study medications were added to losartan 100 mg and other pre-existing antihypertensive treatments.	DB, MC, PC, RCT  Hypertensive patients who were 18 to 85 years of age who had type 2 diabetes and nephropathy	N=599  6 months	Primary: Reduction in albumin:creatinine ratio at 6 months  Secondary: Blood pressure reductions, adverse events	Primary: Treatment with aliskiren 300 mg/day as compared to placebo reduced the mean urinary albumin:creatinine ratio by 20% (95% CI, 9 to 30; P<0.001), with a reduction of 50% or more in 24.7% of the patients who received aliskiren as compared to 12.5% of those who received placebo (P<0.001).  Secondary: A small difference in blood pressure was seen between the treatment groups by the end of the study period with SBP and DBP pressures 2 and 1 mm Hg lower, respectively, in the aliskiren group (P=0.07 and P=0.08, respectively).  The total numbers of adverse and serious adverse events were similar in the groups.
<b>Miscellaneous</b>				
Solomon et al. <sup>57</sup> (2009) ALLAY  Aliskiren 300 mg QD  vs	AC, RCT  Adults with HTN and increased left ventricular wall thickness	N=465  9 months	Primary: Change in left ventricular mass  Secondary: Not reported	Primary: There were reductions in left ventricular mass from baseline in all treatment groups, with 4.9 g/m <sup>2</sup> (5.4%), 4.8 g/m <sup>2</sup> (4.7%), and 5.8 g/m <sup>2</sup> (6.4%) reductions in the aliskiren, losartan, and combination arms, respectively (P<0.0001 for all treatment groups).  The reduction in left ventricular mass in the combination group was not significantly different from that with losartan alone (P=0.52).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
losartan 100 mg QD  vs  aliskiren 300 mg and losartan 100 mg QD				The difference in left ventricular mass regression between the aliskiren and losartan arms was within the prespecified non-inferiority margin, suggesting that aliskiren was as effective as losartan in reducing left ventricular hypertrophy (P<0.0001 for non-inferiority).  Secondary: Not reported
McMurray et al. <sup>58</sup> (2008) ALOFT  Aliskiren 150 mg QD  vs  placebo	DB, MC, PC, RCT  Patients ≥18 years of age with NYHA class II to IV heart failure, current or past history of NTH, and plasma brain natriuretic peptide concentration >100 pg/mL who had been treated with an ACE inhibitor (or angiotensin receptor blocker) and β-blocker	N=302  3 months	Primary: N-terminal pro-brain natriuretic peptide, brain natriuretic peptide, aldosterone, signs and symptoms of heart failure echocardiographic measures of cardiac size and ventricular function, blood pressure, heart rate variability, quality of life, neurohumoral and inflammatory biomarkers, and glycemic measures  Secondary: Not reported	Primary: Plasma N-terminal pro- brain natriuretic peptide increased by 762 pg/mL with placebo and decreased by 244 pg/mL with aliskiren (P=0.0106).  Brain natriuretic peptide decreased by a mean of 12.2 pg/mL in the placebo group and by 61.0 pg/mL in the aliskiren group (P=0.0160).  Plasma aldosterone did not differ between groups. Urinary aldosterone decreased with aliskiren by 9.24 nmol/day and by 6.96 nmol/day with placebo (P=0.0150).  Plasma renin activity decreased 5.71 ng·mL <sup>-1</sup> ·h <sup>-1</sup> with aliskiren compared to a decrease of 0.97 ng·mL <sup>-1</sup> ·h <sup>-1</sup> with placebo (P<0.0001).  There was no difference between treatments for change in signs or symptoms of heart failure, echocardiographic measurements of wall thickness, chamber volumes, or LVEF.  The mean decrease in seated systolic blood pressure was 1.7 mm Hg in the placebo group and 4.1 mm Hg in the aliskiren group (P=0.2257). The mean decrease in seated diastolic blood pressure was 0.2 mm Hg in the placebo group and 2.9 mm Hg in the aliskiren group (P=0.0599). The mean increase in seated heart rate was 0.2 bpm in the placebo group and 1.1 bpm in the aliskiren group (P=0.6774).  Mean standing systolic blood pressure decreased by 1.7 mm Hg in the placebo group and by 3.5 mm Hg in the aliskiren group (P=0.497). The mean standing diastolic blood pressure increased by 0.7 mm Hg with

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>placebo and decreased by 3.5 mm Hg with aliskiren (P=0.0045). The mean standing heart rate decreased by 0.3 bpm in the placebo group and increased by 0.7 bpm in the aliskiren group (P=0.466).</p> <p>There were no differences between treatments in any of the other prespecified comparisons, including autonomic measurements, the Kansas City Cardiomyopathy questionnaire, inflammatory and other plasma and urinary biomarkers (including urinary protein excretion), or measurements of glucose/insulin metabolism.</p> <p>Secondary: Not reported</p>

**IX. Cost**

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of '\$' signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 10. Relative Cost of the Renin Inhibitors**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost
<b>Single Entity Agents</b>				
Aliskiren	tablet	Tekturna <sup>®</sup> *	\$\$\$\$\$	\$\$\$\$\$
<b>Combination Products</b>				
Aliskiren and HCTZ	tablet	Tekturna HCT <sup>®</sup>	\$\$\$\$\$	\$\$\$\$\$

\*Generic is available in at least one dosage form or strength.  
HCTZ=hydrochlorothiazide, N/A=not available

**X. Conclusions**

Aliskiren is the only renin inhibitor in this class and it is approved for the treatment of hypertension.<sup>6-7</sup> It is available as a single entity product, as well as in combination with hydrochlorothiazide. Aliskiren is available generically.

There are several national and international organizations that have published guidelines on the treatment of hypertension. Most of the guidelines do not address the use of the renin inhibitors, with the exception of European Society of Hypertension and European Society of Cardiology which state that evidence is available to justify the use of aliskiren for the management of hypertension, particularly in combination with other antihypertensive agents.<sup>9-17</sup> Thiazide-type diuretics are frequently recommended as initial therapy in patients with uncomplicated hypertension. According to the National Heart, Lung, and Blood Institute's Eighth Report of The Joint National

Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 8), thiazide-type diuretics should be utilized first-line for most patients with hypertension, either alone or in combination with another antihypertensive from a different medication class (e.g., ACE inhibitors, ARBs,  $\beta$ -blockers, calcium channel blockers).<sup>9</sup> Several guidelines consistently recommend that the selection of an antihypertensive agent be based on compelling indications for use.<sup>9-17</sup> Most patients will require more than one antihypertensive medication to achieve blood pressure goals.<sup>9-17</sup>

Several clinical trials have demonstrated that renin inhibitors effectively lower blood pressure. The reduction in blood pressure with aliskiren monotherapy was similar to monotherapy with ACE inhibitors, angiotensin II receptor blockers,  $\beta$ -blockers, and dihydropyridines. In clinical trials comparing combination therapy to monotherapy, the more aggressive treatment regimen lowered blood pressure to a greater extent than the less-intensive treatment regimen.<sup>20-58</sup> Most patients will require more than one antihypertensive medication to achieve blood pressure goals.<sup>9-17</sup> The use of a fixed-dose combination product may simplify the treatment regimen and improve adherence.<sup>11,12,14</sup> However, there are no prospective, randomized trials that have demonstrated better clinical outcomes with a fixed-dose combination product compared to the coadministration of the individual components as separate formulations. Aliskiren is not recommended for use in combination with ACE inhibitors or ARBs, largely due to the findings of the ALITITUDE trial in which the risk of renal impairment, hypotension, and hyperkalemia increased in patients with GFR <60 mL/min and patients with diabetes.<sup>6-8,18</sup> Aliskiren has been shown to have positive effects on surrogate markers of cardiovascular and renal damage in patients with type 2 diabetes and nephropathy, heart failure and left ventricular hypertrophy.<sup>55-58</sup> However, the effects of aliskiren on hard cardiovascular and renal endpoints have not been established.

At this time, there is insufficient evidence to conclude that the renin inhibitors offer a significant clinical advantage over other alternatives in general use. Therefore, all brand renin inhibitors within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

## **XI. Recommendations**

No brand renin inhibitor is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

**Alabama Medicaid Agency  
Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Loop Diuretics  
AHFS Class 402808  
May 4, 2022**

**I. Overview**

Diuretics are commonly used for the treatment of hypertension, heart failure, and various edematous conditions.<sup>1,2</sup> These agents act at different sites within the nephron, which leads to the increased urinary excretion of sodium, chloride and water.<sup>2</sup> The diuretics are categorized into several different AHFS classes, including loop diuretics, potassium-sparing diuretics, thiazide diuretics, thiazide-like diuretics, vasopressin antagonists, and miscellaneous diuretics. The agents which make up these classes differ with regards to their Food and Drug Administration (FDA)-approved indications, mechanism of action, efficacy, safety profiles, tolerability, and ease of use.

The loop diuretics are approved for the treatment of edema and hypertension.<sup>3-6</sup> They primarily act in the thick ascending limb of the loop of Henle to increase the urinary excretion of sodium, chloride, and water. Furosemide and ethacrynic acid also inhibit the absorption of sodium and chloride in the proximal and distal tubules. Bumetanide may also have an additional action in the proximal tubule. The loop diuretics are considered to be the most potent diuretics.<sup>3-7</sup> When given at their maximum dosages, they can lead to the excretion of up to 20% to 25% of the filtered sodium. As renal function declines (glomerular filtration rate <30 mL/minute), a loop diuretic should be considered rather than a thiazide diuretic. Loop diuretics do not possess the added property of arterial vasodilation, as seen with the thiazide diuretics.<sup>1,2</sup> Some studies have suggested that hydrochlorothiazide (a thiazide diuretic) is more effective in lowering blood pressure than the loop diuretics.<sup>8</sup>

The loop diuretics that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. All agents are available in a generic formulation. This class was last reviewed in February 2020.

**Table 1. Loop Diuretics Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
Bumetanide	injection, tablet	N/A	bumetanide
Ethacrynate sodium	injection^	Sodium Edocrin <sup>®*</sup>	none
Ethacrynic acid	tablet	Edocrin <sup>®*</sup>	ethacrynic acid
Furosemide	injection, solution, tablet	Lasix <sup>®*</sup>	furosemide
Torsemide	tablet	N/A	torsemide

\*Generic is available in at least one dosage form or strength.

^Product is primarily administered in an institution.

PDL=Preferred Drug List

N/A=Not available

**II. Evidence-Based Medicine and Current Treatment Guidelines**

Current treatment guidelines that incorporate the use of the loop diuretics are summarized in Table 2.

**Table 2. Treatment Guidelines Using the Loop Diuretics**

Clinical Guideline	Recommendation(s)
American Heart Association/American College of Cardiology/Heart Failure Society of America: 2022 AHA/ACC/HFSA Guideline for the Management of Heart Failure	<b>Treatment of Stage A heart failure (HF)</b> <ul style="list-style-type: none"> <li>Hypertension should be controlled in accordance with guideline-directed medication therapy for hypertension to prevent symptomatic HF. (LoE: A)</li> <li>In patients with type 2 diabetes and either established CVD or at high cardiovascular risk, SGLT-2 inhibitors should be used to prevent hospitalizations for HF. (LoE: A)</li> <li>In the general population, healthy lifestyle habits such as regular physical activity, maintaining normal weight, healthy dietary patterns, and avoiding</li> </ul>

Clinical Guideline	Recommendation(s)
(2022) <sup>9</sup>	<p>smoking are helpful to reduce future risk of HF. (LoE: B)</p> <ul style="list-style-type: none"> <li>● Patients at risk of developing HF, natriuretic peptide biomarker-based screening followed by team-based care, including a cardiovascular specialist optimizing therapy, can be useful to prevent the development of LV dysfunction (systolic or diastolic) or new-onset HF. (LoE: B)</li> </ul> <p><u>Treatment of Stage B heart failure</u></p> <ul style="list-style-type: none"> <li>● In patients with LVEF≤40%, ACE inhibitors should be used to prevent HF and reduce mortality. (LoE: A)</li> <li>● In patients with a recent or remote history of MI or ACS, statins should be used to prevent symptomatic HF and adverse cardiovascular events. (LoE: A)</li> <li>● In patients with a recent MI and LVEF≤40% who are intolerant to ACE inhibitors, ARB should be used to prevent symptomatic HF and reduce mortality. (LoE: B)</li> <li>● In patients with a recent or remote history of MI or ACS and LVEF≤40%, evidence-based beta blockers should be used to reduce mortality. (LoE: B)</li> <li>● In patients who are at least 40 days post-MI with LVEF ≤30% and NYHA class I symptoms while receiving guideline-directed medication therapy and have reasonable expectation of meaningful survival for greater than one year, an implantable cardioverter-defibrillator is recommended for primary prevention of sudden cardiac death to reduce total mortality. (LoE: B)</li> <li>● In patients with LVEF ≤40%, beta blockers should be used to prevent symptomatic HF. (LoE: C)</li> <li>● In patients with LVEF ≤50%, thiazolidinediones should not be used because they increase the risk of HF, including hospitalizations. (LoE: B)</li> <li>● In patients with LVEF ≤50%, nondihydropyridine calcium channel blockers with negative inotropic effects may be harmful. (LoE: C)</li> </ul> <p><u>Treatment for Stage C Heart Failure with Reduced Ejection Fraction (HFrEF)</u></p> <ul style="list-style-type: none"> <li>● For patients with stage C HF, avoiding excessive sodium intake is reasonable to reduce congestive symptoms. (LoE: C)</li> <li>● In patients with HF who have fluid retention, diuretics are recommended to relieve congestion, improve symptoms, and prevent worsening HF. (LoE: B)</li> <li>● For patients with HF and congestive symptoms, addition of a thiazide (e.g., metolazone) to treatment with a loop diuretic should be reserved for patients who do not respond to moderate or high dose loop diuretics to minimize electrolyte abnormalities. (LoE: B)</li> <li>● In patients with HFrEF and NYHA class II to III symptoms, the use of an ARNI is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>● In patients with previous or current symptoms of chronic HFrEF, the use of an ACE inhibitor is beneficial to reduce morbidity and mortality when the use of an ARNI is not feasible. (LoE: A)</li> <li>● In patients with previous or current symptoms of chronic HFrEF, who are intolerant to an ACE inhibitor because of cough or angioedema, and when the use of an ARNI is not feasible, the use of an ARB is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>● In patients with chronic symptomatic HFrEF NYHA class II or III who tolerate an ACE inhibitor or ARB, replacement by an ARNI is recommended to further reduce morbidity and mortality. (LoE: B)</li> <li>● ARNIs should not be administered concomitantly with ACE inhibitors or within 36 hours of the last dose of an ACE inhibitor. (LoE: B)</li> <li>● ARNI or ACE inhibitors should not be administered in patients with a history of angioedema. (LoE: C)</li> <li>● In patients with HFrEF, with current or previous symptoms, use of one of the</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>three <math>\beta</math>-blockers proven to reduce mortality (e.g., bisoprolol, carvedilol, sustained-release metoprolol succinate) is recommended to reduce mortality and hospitalizations. (LoE: A)</p> <ul style="list-style-type: none"> <li>• In patients with HFrEF and NYHA class II to IV symptoms, a mineralocorticoid receptor antagonist (spironolactone or eplerenone) is recommended to reduce morbidity and mortality, if eGFR is <math>&gt;30</math> mL/min/1.73 m<sup>2</sup> and serum potassium is <math>&lt;5.0</math> mEq/L. Careful monitoring of potassium, renal function, and diuretic dosing should be performed at initiation and closely followed thereafter to minimize risk of hyperkalemia and renal insufficiency. (LoE: A)</li> <li>• In patients taking a mineralocorticoid receptor antagonist whose serum potassium cannot be maintained at <math>&lt;5.5</math> mEq/L, mineralocorticoid receptor antagonist should be discontinued to avoid life threatening hyperkalemia. (LoE: B)</li> <li>• In patients with symptomatic chronic HFrEF, SGLT-2 an inhibitor is recommended to reduce hospitalization for HF and cardiovascular mortality, irrespective of the presence of type 2 diabetes. (LoE: A)</li> <li>• The combination of hydralazine and isosorbide dinitrate is recommended to improve symptoms and reduce morbidity and mortality for patients self-identified as African Americans with NYHA class III to IV HFrEF receiving optimal therapy. (LoE: A)</li> <li>• In patients with current or previous symptomatic HFrEF who cannot be given first-line agents, such as an ARNI, ACE inhibitor or ARB because of drug intolerance or renal insufficiency, a combination of hydralazine and isosorbide dinitrate might be considered to reduce morbidity and mortality. (LoE: C)</li> <li>• In patients with HF class II to IV symptoms, omega-3 polyunsaturated fatty acid supplementation may be reasonable to use as adjunctive therapy to reduce mortality and cardiovascular hospitalizations. (LoE: B)</li> <li>• In patients with chronic HFrEF without specific indication (e.g., venous thromboembolism, atrial fibrillation, a previous thromboembolic event, or a cardioembolic source, anticoagulation is not recommended. (LoE: B)</li> <li>• Dihydropyridine and non-dihydropyridine calcium channel blockers are not recommended for patients with HFrEF. (LoE: A)</li> <li>• In patients with HFrEF, vitamins, nutritional supplements, and hormonal therapy are not recommended other than to correct specific deficiencies. (LoE: B)</li> <li>• In patients with HFrEF, class IC antiarrhythmic medication and dronedarone may increase risk of mortality. (LoE: A)</li> <li>• In patients with HFrEF, thiazolidinediones increase the risk of worsening HF symptoms and hospitalizations. (LoE: A)</li> <li>• In patients with type 2 diabetes and high cardiovascular risk, the DPP-4 inhibitors, saxagliptin and alogliptin, increase the risk of HF hospitalization and should be avoided in patients with HF. (LoE: B)</li> <li>• In patients with HFrEF, nonsteroidal anti-inflammatory drugs worsen HF symptoms and should be avoided or withdrawn whenever possible. (LoE: B)</li> <li>• For patients with symptomatic (NYHA class II to III) stable chronic HFrEF (LVEF <math>\leq 35\%</math>) who are receiving guideline-directed medical therapy, including a maximally tolerated dose of a beta blocker, and who are in sinus rhythm with a heart rate of <math>\geq 70</math> beats per minute at rest, ivabradine can be beneficial to reduce HF hospitalizations and cardiovascular death. (LoE: B)</li> <li>• In patients with symptomatic HFrEF despite guideline-directed medical therapy or who are unable to tolerate guideline-directed medical therapy, digoxin might be considered to decrease hospitalizations for HF. (LoE: B)</li> <li>• In select high-risk patients with HFrEF and recent worsening of HF already on guideline-directed medical therapy, an oral soluble guanylate cyclase stimulator (vericiguat) may be considered to reduce HF hospitalization and cardiovascular death. (LoE: B)</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><u>Pharmacological treatment for Stage C HF with mildly reduced EF and improved EF</u></p> <ul style="list-style-type: none"> <li>• In patients with HF with mildly reduced EF, SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• Among patients with current or previous symptomatic HF with mildly reduced EF (LVEF, 41 to 49%), use of evidence-based beta blockers for HFrEF, ARNI, ACE inhibitor or ARB, and mineralocorticoid receptor antagonists may be considered to reduce the risk of HF hospitalization and cardiovascular mortality, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• In patients with HF with improved EF after treatment, guideline-directed medical therapy should be continued to prevent relapse of HF and LV dysfunction, even in patients who may become asymptomatic. (LoE: B)</li> </ul> <p><u>Pharmacological treatment for Stage C HF with preserved EF (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• Patients with hypertension and HFpEF should have medication titrated to attain blood pressure targets in accordance with published clinical practice guidelines to prevent morbidity. (LoE: C)</li> <li>• SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• In patients with HFpEF, the use of a mineralocorticoid receptor antagonist, ARB, or ARNI may be considered to decrease hospitalizations, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• Routine use of nitrates or phosphodiesterase-5 inhibitors to increase activity or quality of life in patients with HFpEF is ineffective. (LoE: B)</li> </ul> <p><u>Treatment of Stage D (advanced/refractory) HF</u></p> <ul style="list-style-type: none"> <li>• For patients with advanced HF and hyponatremia, the benefit of fluid restriction to reduce congestive symptoms is uncertain. (LoE: C)</li> <li>• Continuous intravenous inotropic support is reasonable as “bridge therapy” in patients with HF (Stage D) refractory to guideline-directed medical therapy and device therapy who are eligible for and awaiting mechanical circulatory support or cardiac transplantation. (LoE: B)</li> <li>• In select patients with HF Stage D, despite optimal guideline-directed medical therapy and device therapy who are ineligible for either mechanical circulatory support or cardiac transplantation, continuous intravenous inotropic support may be considered as palliative therapy for symptom control and improvement in functional status. (LoE: B)</li> <li>• Long-term use of either continuous or intermittent, intravenous inotropic agents, for reasons other than palliative care or as a bridge to advanced therapies, is potentially harmful. (LoE: B)</li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure (2021)</b><sup>10</sup></p>	<p><u>Pharmacological treatments indicated in patients with (NYHA Class II-IV) heart failure with reduced ejection fraction</u></p> <ul style="list-style-type: none"> <li>• An ACE inhibitor is recommended, in addition to a <math>\beta</math>-blocker, for symptomatic patients with HFrEF to reduce the risk of HF hospitalization and death.</li> <li>• A mineralocorticoid receptor antagonist (MRA) is recommended for patients with HFrEF, who remain symptomatic despite treatment with an ACE inhibitor and a <math>\beta</math>-blocker, to reduce the risk of HF hospitalization and death.</li> <li>• Dapagliflozin or empagliflozin are recommended for patients with HFrEF to reduce the risk of HF hospitalization and death. Dapagliflozin or empagliflozin are recommended, in addition to optimal medical therapy with an ACE-I/ARNI, a <math>\beta</math>-blocker and an MRA, for patients with HFrEF regardless of diabetes status.</li> <li>• Sacubitril-valsartan is recommended as a replacement for an ACE inhibitor to further reduce the risk of HF hospitalization and death in ambulatory patients with HFrEF who remain symptomatic despite optimal treatment with an ACE inhibitor, a <math>\beta</math>-blocker, and a mineralocorticoid receptor antagonist.</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• Diuretics are recommended in order to improve symptoms and exercise capacity in patients with signs and/or symptoms of congestion.</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization or cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm despite treatment with an evidence-based dose of <math>\beta</math>-blocker (or maximum tolerated dose below that), ACE inhibitor (or ARB), and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm who are unable to tolerate or have contraindications for a <math>\beta</math>-blocker. Patients should also receive an ACE inhibitor (or ARB) and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• An ARB is recommended to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients unable to tolerate an ACE inhibitor (patients should also receive a <math>\beta</math>-blocker and mineralocorticoid receptor antagonist).</li> <li>• An ARB may be considered to reduce the risk of HF hospitalization and death in patients who are symptomatic despite treatment with a <math>\beta</math>-blocker who are unable to tolerate a mineralocorticoid receptor antagonist.</li> <li>• Vericiguat may be considered in patients in NYHA class II-IV who have had worsening HF despite treatment with an ACE-I (or ARNI), a <math>\beta</math>-blocker and an MRA to reduce the risk of CV mortality or HF hospitalization.</li> <li>• Hydralazine and isosorbide dinitrate should be considered in self-identified black patients with LVEF <math>\leq 35\%</math> or with an LVEF <math>&lt; 45\%</math> combined with a dilated LV in NYHA Class III-IV despite treatment with an ACE-I a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist to reduce the risk of HF hospitalization and death.</li> <li>• Hydralazine and isosorbide dinitrate may be considered in symptomatic patients with HFrEF who can tolerate neither an ACE inhibitor nor an ARB (or they are contraindicated) to reduce the risk of death.</li> <li>• Digoxin is a treatment with less-certain benefits and may be considered in symptomatic patients in sinus rhythm despite treatment with an ACE inhibitor (or ARB), a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist, to reduce the risk of hospitalization (both all-cause and HF-hospitalizations).</li> </ul> <p><u>Recommendations for treatment of patients with (NYHA class II-IV) heart failure with mildly reduced ejection fraction (HFmrEF)</u></p> <ul style="list-style-type: none"> <li>• Diuretics are recommended in patients with congestion and HFmrEF in order to alleviate symptoms and signs.</li> <li>• An ACE inhibitor may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An ARB may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• A <math>\beta</math>-blocker may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An MRA may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• Sacubitril/valsartan may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> </ul> <p><u>Recommendations for treatment of patients with heart failure with preserved ejection fraction (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• It is recommended to screen patients with HFpEF for both cardiovascular and noncardiovascular comorbidities, which, if present, should be treated provided safe and effective interventions exist to improve symptoms, well-being and/or</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>prognosis.</p> <ul style="list-style-type: none"> <li>• Diuretics are recommended in congested patients with HFpEF in order to alleviate symptoms and signs.</li> </ul> <p><u>Recommendations for the primary prevention of heart failure in patients with risk factors for its development</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension is recommended to prevent or delay the onset of HF and prolong life.</li> <li>• Treatment with statins is recommended in patients at high risk of CV disease or with CV disease in order to prevent or delay the onset of HF, and to prevent HF hospitalizations.</li> <li>• SGLT2 inhibitors (canagliflozin, dapagliflozin, empagliflozin, ertugliflozin, sotagliflozin) are recommended in patients with diabetes at high risk of CV disease or with CV disease in order to prevent HF hospitalizations.</li> <li>• Counselling against sedentary habit, obesity, cigarette smoking, and alcohol abuse is recommended to prevent or delay the onset of HF.</li> </ul> <p><u>Recommendations for the initial management of patients with acute heart failure – pharmacotherapy</u></p> <ul style="list-style-type: none"> <li>• Intravenous loop diuretics are recommended for all patients with acute HF admitted with signs/symptoms of fluid overload to improve symptoms. It is recommended to regularly monitor symptoms, urine output, renal function and electrolytes during use of intravenous diuretics.</li> <li>• Combination of a loop diuretic with thiazide type diuretic should be considered in patients with resistant oedema who do not respond to an increase in loop diuretic doses.</li> <li>• In patients with acute HF and SBP &gt;110 mmHg, intravenous vasodilators may be considered as initial therapy to improve symptoms and reduce congestion.</li> <li>• Inotropic agents may be considered in patients with SBP &lt;90 mmHg and evidence of hypoperfusion who do not respond to standard treatment, including fluid challenge, to improve peripheral perfusion and maintain end-organ function.</li> <li>• Inotropic agents are not recommended routinely, due to safety concerns, unless the patient has symptomatic hypotension and evidence of hypoperfusion.</li> <li>• A vasopressor, preferably norepinephrine, may be considered in patients with cardiogenic shock to increase blood pressure and vital organ perfusion.</li> <li>• Thromboembolism prophylaxis (e.g. with LMWH) is recommended in patients not already anticoagulated and with no contraindication to anticoagulation, to reduce the risk of deep venous thrombosis and pulmonary embolism.</li> <li>• Routine use of opiates is not recommended, unless in selected patients with severe/intractable pain or anxiety.</li> </ul>
<p>Eighth Joint National Committee (JNC 8): <b>2014 Evidence-based Guideline for the Management of High Blood Pressure in Adults (2014)</b><sup>11</sup></p>	<ul style="list-style-type: none"> <li>• Pharmacologic treatment should be initiated in patients ≥60 years of age to lower blood pressure at systolic blood pressure ≥150 mm Hg or diastolic blood pressure ≥90 mm Hg and to a goal systolic blood pressure &lt;150 mm Hg and goal diastolic blood pressure &lt;90 mm Hg. Adjustment of treatment is not necessary if treatment results in lower blood pressure and treatment is well tolerated and without adverse effects on health or quality of life.</li> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at diastolic blood pressure ≥90 mm Hg to a goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥150 mm Hg to a goal diastolic blood pressure &lt;140 mm Hg.</li> <li>• For patients ≥18 years of age with chronic kidney disease or diabetes, pharmacologic treatment should be initiated to lower blood pressure at systolic</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>blood pressure <math>\geq 140</math> mm Hg or diastolic blood pressure <math>\geq 90</math> mm Hg and to a goal systolic blood pressure <math>&lt; 140</math> mm Hg and goal diastolic blood pressure <math>&lt; 90</math> mm Hg.</p> <ul style="list-style-type: none"> <li>• Initial antihypertensive treatment for the general nonblack population, including those with diabetes, should include thiazide-type diuretic, calcium channel blocker (CCB), ACE inhibitor, or ARB.</li> <li>• Initial antihypertensive treatment for the general black population, including those with diabetes, should include thiazide-type diuretic or CCB.</li> <li>• For patients <math>\geq 18</math> years of age with chronic kidney disease regardless of race or diabetes status, initial (or add-on) treatment should include an ACE inhibitor or ARB to improve kidney outcomes.</li> <li>• The main goal of antihypertensive treatment is to attain and maintain goal blood pressure.</li> <li>• If goal blood pressure is not attained within a month of treatment, the dose of the initial drug should be increased or second drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• If goal is not achieved with two drugs, a third drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• An ACE inhibitor and ARB should not be used together.</li> <li>• Antihypertensive classes can be used if the patient is unable to achieve goal blood pressure with three agents or had a contraindication to a preferred class.</li> <li>• If blood pressure is not able to be achieved or in complicated patients, referral to a hypertension specialist may be indicated.</li> </ul>
<p>International Society of Hypertension: <b>Global Hypertension Practice Guidelines (2020)</b><sup>12</sup></p>	<p><u>Lifestyle modifications</u></p> <ul style="list-style-type: none"> <li>• Lifestyle modification is the first line of antihypertensive treatment.</li> <li>• Salt reduction: Reduce salt added when preparing foods, and at the table. Avoid or limit consumption of high salt foods such as soy sauce, fast foods and processed food including breads and cereals high in salt.</li> <li>• Healthy diet: Eating a diet that is rich in whole grains, fruits, vegetables, polyunsaturated fats and dairy products and reducing food high in sugar, saturated fat and trans fats, such as the DASH diet.</li> <li>• Healthy drinks: Moderate consumption of coffee, green and black tea. Other beverages that can be beneficial include karkadé (hibiscus) tea, pomegranate juice, beetroot juice and cocoa.</li> <li>• Moderation of alcohol consumption: The recommended daily limit for alcohol consumptions is 2 standard drinks for men and 1.5 for women (10 g alcohol/standard drink). Avoid binge drinking.</li> <li>• Weight reduction: Body weight control is indicated to avoid obesity. Particularly abdominal obesity should be managed. Ethnic-specific cut-offs for BMI and waist circumference should be used. Alternatively, a waist-to-height ratio <math>&lt; 0.5</math> is recommended for all populations.</li> <li>• Smoking cessation: Smoking is a major risk factor for cardiovascular disease (CVD), COPD and cancer. Smoking cessation and referral to smoking cessation programs are advised.</li> <li>• Regular physical activity: Studies suggest that regular aerobic and resistance exercise may be beneficial for both the prevention and treatment of hypertension. Moderate intensity aerobic exercise (walking, jogging, cycling, yoga, or swimming) for 30 minutes on five to seven days per week Strength training also can help reduce blood pressure. Performance of resistance/strength exercises on two to three days per week.</li> <li>• Reduce stress and induce mindfulness: Stress should be reduced and mindfulness or meditation introduced into the daily routine.</li> <li>• Reduce exposure to air pollution and cold temperature: Evidence from studies support a negative effect of air pollution on blood pressure in the long-term.</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><b>Pharmacological Treatment</b></p> <ul style="list-style-type: none"> <li>• Ideal characteristics of drug treatment           <ul style="list-style-type: none"> <li>○ Treatments should be evidence-based in relation to morbidity/mortality prevention.</li> <li>○ Use a once-daily regimen which provides 24-hour blood pressure control.</li> <li>○ Treatment should be affordable and/or cost-effective relative to other agents.</li> <li>○ Treatments should be well-tolerated.</li> <li>○ Evidence of benefits of use of the medication in populations to which it is to be applied.</li> </ul> </li> <li>• General scheme for drug treatment           <ul style="list-style-type: none"> <li>○ Lifestyle modification is the first line of antihypertensive treatment.</li> <li>○ Grade 1 hypertension (BP 140 to 159/ 90 to 99): Immediate drug treatment in high-risk patients or those with CVD, chronic kidney disease (CKD), diabetes mellitus (DM), or hypertension-mediated organ damage (HMOD). Drug treatment after three to six months of lifestyle intervention if BP still not controlled in low to moderate risk patients.</li> <li>○ Grade 2 hypertension (BP <math>\geq</math>160/100): Immediate drug treatment in all patients.</li> </ul> </li> <li>• Core drug-treatment strategy           <ul style="list-style-type: none"> <li>○ Step 1: Dual low-dose combination (ACE inhibitor or ARB plus dihydropyridine-calcium channel blockers (DHP-CCB)); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance; consider ACE/ARB plus DHP-CCB or DHP-CCB plus thiazide-like diuretics in black patients.</li> <li>○ Step 2: Dual full-dose combination (ACE inhibitor or ARB plus DHP-CCB); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance.</li> <li>○ Step 3: Triple combination (ACE/ARB plus DHP-CCB plus thiazide-like diuretic).</li> <li>○ Step 4, resistant hypertension: triple combination plus spironolactone or other drug, alternatives include amiloride, doxazosin, eplerenone, clonidine, or <math>\beta</math>-blocker. Caution with spironolactone or other potassium sparing diuretics when estimated GFR <math>&lt;</math>45 mL/min/1.73m<sup>2</sup> or K<sup>+</sup> <math>&gt;</math>4.5 mmol/L.</li> <li>○ Consider <math>\beta</math>-blockers at any treatment step when there is a specific indications for their use, e.g., heart failure, angina, post-MI, atrial fibrillation, or younger women planning pregnancy or pregnant.</li> </ul> </li> </ul>
<p>Hypertension Canada: 2020 Guidelines for the Prevention, Diagnosis, Risk Assessment, and Treatment of Hypertension in Adults and Children (2020)<sup>13</sup></p>	<p><b>Indications for drug therapy for adults with hypertension without compelling indications for specific agents</b></p> <ul style="list-style-type: none"> <li>• Antihypertensive therapy should be prescribed for average diastolic blood pressure (DBP) measurements of <math>\geq</math>100 mmHg or average systolic blood pressure (SBP) measurements of <math>\geq</math>160 mmHg in patients without macrovascular target organ damage or other cardiovascular risk factors.</li> <li>• Antihypertensive therapy should be strongly considered for average DPB readings <math>\geq</math>90 mmHg or for average SBP readings <math>\geq</math>140 mmHg in the presence of macrovascular target organ damage or other independent cardiovascular risk factors.</li> <li>• For high-risk patients, aged 50 years or older, with SBP levels <math>\geq</math>130 mmHg, intensive management to target a SBP <math>&lt;</math>120 mmHg should be considered. Patient</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>selection for intensive management is recommended and caution should be taken in certain high-risk groups.</p> <p><u>Indications for drug therapy for adults with diastolic and with or without systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be with either monotherapy or single pill combination (SPC). <ul style="list-style-type: none"> <li>○ Recommended monotherapy choices are: <ul style="list-style-type: none"> <li>▪ A thiazide/thiazide-like diuretic, with longer-acting diuretics preferred;</li> <li>▪ A <math>\beta</math>-blocker (in patients &lt;60 years of age);</li> <li>▪ An angiotensin-converting enzyme (ACE) inhibitor (in nonblack patients);</li> <li>▪ An angiotensin receptor blocker (ARB); or</li> <li>▪ A long-acting calcium channel blocker (CCB).</li> </ul> </li> <li>○ Recommended SPC choices are those in which an ACE inhibitor is combined with a CCB, ARB with a CCB, or ACE inhibitor or ARB with a diuretic.</li> <li>○ Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> </ul> </li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line choices. Useful choices include a thiazide/thiazide-like diuretic or CCB with either: ACE inhibitor, ARB, or <math>\beta</math>-blocker. Caution should be exercised in combining a nondihydropyridine CCB and a <math>\beta</math>-blocker. The combination of an ACE inhibitor and an ARB is not recommended.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other antihypertensive drugs may be added.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated hypertension; <math>\beta</math>-blockers are not recommended as first-line therapy for uncomplicated hypertension in patients <math>\geq 60</math> years of age; and ACE inhibitors are not recommended as first-line therapy for uncomplicated hypertension in black patients. However, these agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Indications for drug therapy for adults with isolated systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be single-agent therapy with a thiazide/thiazide-like diuretic, a long-acting dihydropyridine CCB, or an ARB. If there are adverse effects, another drug from this group should be substituted. Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line options.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other classes of drugs (such as <math>\alpha</math>-blockers, ACE inhibitors, centrally acting agents, or nondihydropyridine CCBs) may be combined or substituted.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated isolated systolic hypertension; and <math>\beta</math>-blockers are not recommended as first-line therapy for isolated systolic hypertension in patients <math>\geq 60</math> years of age. However, both agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><u>Guidelines for hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• For most hypertensive patients with CAD, an ACE inhibitor or ARB is recommended.</li> <li>• For hypertensive patients with CAD, but without coexisting systolic heart failure, the combination of an ACE inhibitor and ARB is not recommended.</li> <li>• For high-risk hypertensive patients, when combination therapy is being used, choices should be individualized. The combination of an ACE inhibitor and a dihydropyridine CCB is preferable to an ACE inhibitor and a thiazide/thiazide-like diuretic in selected patients.</li> <li>• For patients with stable angina pectoris but without previous heart failure, myocardial infarction, or coronary artery bypass surgery, either a <math>\beta</math>-blocker or CCB can be used as initial therapy.</li> <li>• Short-acting nifedipine should not be used.</li> <li>• When decreasing SBP to target levels in patients with established CAD (especially if isolated systolic hypertension is present), be cautious when the DBP is <math>\leq 60</math> mmHg because of concerns that myocardial ischemia might be exacerbated, especially in patients with left ventricular hypertrophy (LVH).</li> </ul> <p><u>Guidelines for patients with hypertension who have had a recent myocardial infarction</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should include a <math>\beta</math>-blocker as well as an ACE inhibitor.</li> <li>• An ARB can be used if the patient is intolerant of an ACE inhibitor.</li> <li>• CCBs may be used in patients after myocardial infarction when <math>\beta</math>-blockers are contraindicated or not effective. Nondihydropyridine CCBs should not be used when there is heart failure, evidenced by pulmonary congestion on examination or radiography.</li> </ul> <p><u>Treatment of hypertension in association with heart failure</u></p> <ul style="list-style-type: none"> <li>• In patients with systolic dysfunction (ejection fraction <math>&lt; 40\%</math>), ACE inhibitors and <math>\beta</math>-blockers are recommended for initial therapy. Aldosterone antagonists (mineralocorticoid receptor antagonists) may be combined in treatment for patients with a recent cardiovascular hospitalization, acute myocardial infarction, elevated B-type natriuretic peptide or N-terminal pro-B-type natriuretic peptide level, or New York Heart Association (NYHA) Class II-IV symptoms. Careful monitoring for hyperkalemia is recommended when combining an aldosterone antagonist with ACE inhibitor or ARB treatment. Other diuretics are recommended as additional therapy if needed. Beyond considerations of BP control, doses of ACE inhibitors or ARBs should be titrated to those reported to be effective in trials unless adverse effects become manifest.</li> <li>• An ARB is recommended if ACE inhibitors are not tolerated.</li> <li>• A combination of hydralazine and isosorbide dinitrate is recommended if ACE inhibitors and ARBs are contraindicated or not tolerated.</li> <li>• For hypertensive patients whose BP is not controlled, an ARB may be combined with an ACE inhibitor and other antihypertensive drug treatment. Careful monitoring should be used if combining an ACE inhibitor and an ARB because of potential adverse effects such as hypotension, hyperkalemia, and worsening renal function. Additional therapies may also include dihydropyridine CCBs.</li> <li>• An angiotensin receptor-neprilysin inhibitor (ARNI) should be used in place of an ACE inhibitor or ARB for patients with HFrEF (<math>&lt; 40\%</math>) who remain symptomatic despite treatment with appropriate dose of guideline directed HF therapy. Eligible patients must have a serum potassium <math>&lt; 5.2</math> mmol/L, an eGFR <math>\leq 30</math> mL/min/1.73m<sup>2</sup> and close surveillance of serum potassium and creatinine.</li> </ul> <p><u>Treatment of hypertension in association with stroke</u></p> <ul style="list-style-type: none"> <li>• BP management in acute ischemic stroke (onset to 72 hours)</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> <li>● BP management after acute ischemic stroke <ul style="list-style-type: none"> <li>○ Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack.</li> <li>○ After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently &lt;140/90 mmHg.</li> <li>○ Treatment with an ACE inhibitor and thiazide/thiazide-like diuretic combination is preferred.</li> <li>○ For patients with stroke, the combination of an ACE inhibitor and ARB is not recommended.</li> </ul> </li> <li>● BP management in hemorrhagic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> </ul> <p><u>Treatment of hypertension in association with LVH</u></p> <ul style="list-style-type: none"> <li>● Hypertensive patients with LVH should be treated with antihypertensive therapy to decrease the rate of subsequent cardiovascular events.</li> <li>● The choice of initial therapy can be influenced by the presence of LVH. Initial therapy can be drug treatment using ACE inhibitors, ARBs, long-acting CCBs, or thiazide/thiazide-like diuretics. Direct arterial vasodilators such as hydralazine or minoxidil should not be used.</li> </ul> <p><u>Treatment of hypertension in association with nondiabetic chronic kidney disease</u></p> <ul style="list-style-type: none"> <li>● Individualize BP targets in patients with chronic kidney disease. Consider intensive targets (SBP &lt;120 mmHg) in appropriate patients.</li> <li>● For patients with hypertension and proteinuric chronic kidney disease (urinary protein &gt;150 mg per 24 hours or albumin to creatinine ratio &gt;30 mg/mmol), initial therapy should be an ACE inhibitor or an ARB if there is intolerance to ACE inhibitors.</li> <li>● In most cases, combination therapy with other antihypertensive agents might be needed to reach target BP levels.</li> <li>● The combination of an ACE inhibitor and ARB is not recommended for patients with nonproteinuric chronic kidney disease.</li> </ul> <p><u>Treatment of hypertension in association with renovascular disease</u></p> <ul style="list-style-type: none"> <li>● Patients with hypertension attributable to atherosclerotic renal artery stenosis should be primarily medically managed because renal angioplasty and stenting offers no benefit over optimal medical therapy alone.</li> <li>● Renal artery angioplasty and stenting for atherosclerotic hemodynamically significant renal artery stenosis could be considered for patients with uncontrolled hypertension resistant to maximally tolerated pharmacotherapy, progressive renal function loss, and acute pulmonary edema.</li> <li>● Patients with confirmed renal fibromuscular dysplasia (FMD) should be referred to a hypertension specialist.</li> <li>● Renal artery angioplasty without stenting is recommended for treatment of FMD-related renal artery stenosis. Stenting is not recommended unless needed because of a periprocedural dissection. Surgical revascularization should be considered in cases of complex lesions less amendable to angioplasty, stenosis associated with complex aneurysm, and restenosis despite two unsuccessful attempts of angioplasty.</li> </ul> <p><u>Treatment of hypertension in association with diabetes mellitus</u></p> <ul style="list-style-type: none"> <li>● Persons with diabetes mellitus should be treated to attain SBP of &lt;130 mmHg and DBP of &lt;80 mmHg.</li> <li>● For persons with cardiovascular or kidney disease, including microalbuminuria, or with cardiovascular risk factors in addition to diabetes and hypertension, an</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>ACE inhibitor or an ARB is recommended as initial therapy.</p> <ul style="list-style-type: none"> <li>• For persons with diabetes and hypertension not included in other guidelines in this section, appropriate choices include (in alphabetical order): ACE inhibitors, ARBs, dihydropyridine CCBs, and thiazide/thiazide-like diuretics.</li> <li>• If target BP levels are not achieved with standard-dose monotherapy, additional antihypertensive therapy should be used. For persons in whom combination therapy with an ACE inhibitor is being considered, a dihydropyridine CCB is preferable to a thiazide/thiazide-like diuretic.</li> </ul> <p><u>Resistant hypertension</u></p> <ul style="list-style-type: none"> <li>• Resistant hypertension is defined as BP above target despite three or more BP-lowering drugs at optimal doses preferably including a diuretic (and usually a renin-angiotensin-aldosterone system blocker and a CCB).</li> <li>• Accurate office and out-of-office BP measurement is essential.</li> <li>• Other reasons for apparent resistant hypertension should be eliminated before diagnosing true resistant hypertension, including nonadherence, white coat effect, and secondary hypertension.</li> <li>• Pharmacotherapy with the additional use of spironolactone, bisoprolol, doxazosin, amiloride, eplerenone, or clonidine with the baseline regimen decreases BP significantly, with the greatest BP-lowering shown with spironolactone.</li> <li>• Patients with resistant hypertension should be referred to providers with expertise in diagnosis and management of hypertension.</li> </ul> <p><u>Hypertension and pediatrics</u></p> <ul style="list-style-type: none"> <li>• BP should be measured regularly in children three years of age or older; the auscultatory method is the gold-standard at present.</li> <li>• Initial therapy should be monotherapy, with an ACE inhibitor or ARB (not first-line in black children), or a long-acting dihydropyridine CCB.</li> <li>• The treatment goal is systolic and diastolic office BP and/or ABPM &lt; 95th percentile or &lt;90<sup>th</sup> percentile in children with risk factors or target organ damage.</li> <li>• Complex cases should be referred to an expert in pediatric hypertension.</li> </ul> <p><u>Hypertension and pregnancy</u></p> <ul style="list-style-type: none"> <li>• Up to 7% of pregnancies are complicated by a hypertensive disorder of pregnancy, and approximately 5% of women will have chronic hypertension when they become pregnant.</li> <li>• The prevalence of hypertension in pregnancy is expected to increase with women becoming pregnant later in their reproductive years and the increasing prevalence of cardiovascular comorbidities such as increased preconception body mass index and maternal diabetes.</li> <li>• The possibility of pregnancy should be considered when managing women with hypertension who are of reproductive age.</li> <li>• Preconception counselling should be offered to all women with hypertension who are considering pregnancy.</li> <li>• ACE inhibitor and ARB therapy should be avoided before conception and during pregnancy unless there is a compelling indication for their use (i.e., proteinuric kidney disease).</li> <li>• Hypertension during pregnancy can increase the risk of adverse maternal and fetal outcomes, including an increased risk of preeclampsia, placental abruption, prematurity, small for gestational age infants, stillbirth, and maternal renal and retinal injury, thus generally requires involvement of an interdisciplinary team including obstetrical care providers.</li> <li>• Antihypertensive therapy is recommended for average SBP measurements of</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>≥140 mmHg or DBP measurements of ≥90 mmHg in pregnant women with chronic hypertension, gestational hypertension, or preeclampsia. Initial antihypertensive therapy should be monotherapy from the following first-line drugs: oral labetalol, oral methyldopa, long-acting oral nifedipine, or other oral b-blockers (acebutolol, metoprolol, pindolol, and propranolol). Other antihypertensive drugs can be considered as second-line drugs including: clonidine, hydralazine, and thiazide diuretics.</p> <ul style="list-style-type: none"> <li>• Women with severe hypertension with SBP ≥160 mmHg or DBP ≥110 mmHg in pregnancy or postpartum require urgent antihypertensive therapy because it is considered an obstetrical emergency.</li> <li>• Antihypertensive drugs used in breastfeeding women include: labetalol, methyldopa, long-acting nifedipine, enalapril, or captopril.</li> </ul>
<p>European Society of Hypertension/ European Society of Cardiology: <b>2018 Guidelines for the management of arterial hypertension (2018)</b><sup>14</sup></p>	<p><u>Treatment strategies and choice of antihypertensive drugs</u></p> <ul style="list-style-type: none"> <li>• Diuretics (including thiazides, chlorthalidone, and indapamide), β-blockers, calcium channel blocker (CCB), angiotensin-converting enzyme (ACE) inhibitors, and angiotensin receptor blockers (ARBs) are all suitable for the initiation and maintenance of antihypertensive treatment, either as monotherapy or in some combinations.</li> <li>• Some agents should be considered as the preferential choice in specific conditions because used in trials in those conditions or because of greater effectiveness in specific types of organ damage. Preferred combinations should comprise a renin-angiotensin system (RAS) blocker (either an ACE inhibitor or an ARB) with a CCB or diuretic.</li> <li>• It is recommended that beta-blockers are combined with any of the other major drug classes when there are specific clinical situations, e.g. angina, post-myocardial infarction, heart failure, or heart rate control.</li> <li>• Initiation of antihypertensive therapy with a two-drug combination may be considered in patients with markedly high baseline blood pressure (BP) or at high cardiovascular (CV) risk.</li> <li>• The combination of two antagonists of the RAS is not recommended and should be discouraged.</li> <li>• Other drug combinations should be considered and probably are beneficial in proportion to the extent of BP reduction. However, combinations that have been successfully used in trials may be preferable.</li> <li>• Combinations of two antihypertensive drugs at fixed doses in a single tablet may be recommended and favored, because reducing the number of daily pills improves adherence, which is low in patients with hypertension. Exceptions are frail older patients and those at low risk and with grade one hypertension (particularly if systolic BP is &lt;150 mmHg).</li> <li>• It is recommended that if BP is not controlled with a three-drug combination, treatment should be increased by the addition of spironolactone or, if not tolerated, other diuretics such as amiloride or higher doses of other diuretics, a beta-blocker, or an alpha-blocker.</li> </ul> <p><u>Treatment strategies in white-coat and masked hypertension</u></p> <ul style="list-style-type: none"> <li>• In white-coat hypertensives without additional risk factors, therapeutic intervention may be limited to lifestyle changes only, but this decision should be accompanied by close follow-up.</li> <li>• In white-coat hypertensives with a higher CV risk or hypertension-mediated organ damage, drug treatment may be considered in addition to lifestyle changes.</li> <li>• In masked hypertension, both lifestyle measures and antihypertensive drug treatment should be considered, because this type of hypertension has been consistently found to have a CV risk very close to that of in- and out-of-office hypertension.</li> <li>• Antihypertensive drug up-titration should be considered in treated patients whose</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>out-of-office BP is not controlled (i.e., masked uncontrolled hypertension), because of the high CV risk of these patients.</p> <p><u>Antihypertensive treatment strategies in the elderly</u></p> <ul style="list-style-type: none"> <li>• It is recommended that older patients (<math>\geq 65</math> years) are treated with the same recommendations in non-older patient population. In very old patients (<math>\geq 80</math> years), it may be appropriate to initiate treatment with monotherapy.</li> <li>• In all older patients, when combination therapy is used, it is recommended that this is initiated at the lowest available doses. In all older patients, and especially very old or frail patients, the possible occurrence of postural BP should be closely monitored and symptoms of possible hypotensive episodes checked by ambulatory blood pressure monitoring.</li> <li>• Unless required for concomitant diseases, loop diuretics and alpha-blockers should be avoided because of their association with injurious falls.</li> <li>• Renal function should be frequently assessed to detect possible increases in serum creatinine and reductions in estimated glomerular filtration rate (eGFR) as a result of BP-related reductions in renal perfusion.</li> <li>• When treated, BP should be lowered to a systolic value of 130 to 139 mmHg and a diastolic value of <math>&lt; 80</math> mmHg if tolerated. Treated values of <math>&lt; 130</math> mmHg should be avoided.</li> </ul> <p><u>Treatment strategies in hypertensive women</u></p> <ul style="list-style-type: none"> <li>• Hormone therapy and selective estrogen receptor modulators are not recommended and should not be used for primary or secondary prevention of CVD.</li> <li>• In women with gestational hypertension, pre-existing hypertension superimposed by gestational hypertension, or with hypertension and subclinical organ damage or symptoms, initiation of drug treatments is recommended when SBP is <math>\geq 140</math> mmHg or DBP <math>\geq 90</math> mmHg. In all other cases, initiation of drug treatment is recommended when SBP is <math>\geq 150</math> mmHg or DBP is <math>\geq 95</math> mmHg.</li> <li>• Methyldopa, labetalol, and CCBs are recommended as the drugs of choice for the treatment of hypertension in pregnancy.</li> <li>• ACE inhibitors, ARBs, or direct renin inhibitors are not recommended during pregnancy.</li> <li>• SBP <math>\geq 170</math> mmHg or DBP <math>\geq 110</math> mmHg in a pregnant woman is an emergency, and admission to hospital is recommended.</li> <li>• In severe hypertension, drug treatment with intravenous (IV) labetalol, oral methyldopa, or nifedipine is recommended.</li> <li>• The recommended treatment for hypertensive crisis is IV labetalol or nicardipine and magnesium.</li> <li>• In pre-eclampsia associated with pulmonary edema, nitroglycerin given as an IV infusion is recommended.</li> <li>• In women with gestational hypertension or mild-pre-eclampsia, delivery is recommended at 37 weeks.</li> <li>• It is recommended to expedite delivery in pre-eclampsia with adverse conditions, such as visual disturbances or hemostatic disorders</li> <li>• In women at high risk of pre-eclampsia, provided they are at low risk of gastrointestinal hemorrhage, treatment with low dose aspirin from 12 weeks until delivery may be considered.</li> <li>• Methyldopa, labetalol, and nifedipine should be considered preferential antihypertensive drugs in pregnancy. Intravenous labetalol or infusion of nitroprusside should be considered in case of emergency (pre-eclampsia).</li> </ul> <p><u>Treatment strategies in patients with diabetes</u></p>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• Antihypertensive drug treatment is recommended for people with diabetes when office BP is <math>\geq 140/90</math> mmHg.</li> <li>• A SBP goal <math>&lt; 130</math> mmHg is recommended in patients with diabetes and <math>&lt; 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg.</li> <li>• In older people, the target SBP range is 130 to 139 mmHg.</li> <li>• The DBP target in patients with diabetes is recommended to be <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• It is recommended to initiate treatment with a combination of a RAS blocker with a CCB or thiazide/thiazide-like diuretic.</li> <li>• It is recommended that individual drug choice takes comorbidities into account.</li> <li>• Simultaneous administration of two blockers of the RAS is not recommended and should be avoided in patients with diabetes.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with nephropathy</u></p> <ul style="list-style-type: none"> <li>• In patients with diabetic and non-diabetic CKD, it is recommended that an office BP of <math>\geq 140/90</math> mmHg be treated with lifestyle advice and BP-lowering medication.</li> <li>• In patients with diabetic or non-diabetic CKD, it is recommended to lower SBP to a range of 130 to 139 mmHg. And individualized treatments should be considered according to its tolerability and impact on renal function and electrolytes.</li> <li>• A combination of a RAS blocker with a CCB or a diuretic is recommended as initial therapy.</li> <li>• RAS blockers are more effective in reducing albuminuria than other antihypertensive agents, and are indicated in hypertensive patients in the presence of microalbuminuria or overt proteinuria.</li> <li>• Combination of two RAS blockers, though potentially more effective in reducing proteinuria, is not recommended.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with cerebrovascular disease</u></p> <ul style="list-style-type: none"> <li>• In patients with acute intracerebral hemorrhage, immediate BP lowering is not recommended for patients with SBP <math>&lt; 220</math> mmHg. In patients with SBP <math>\geq 220</math> mmHg, care acute BP lowering with IV therapy to <math>&lt; 180</math> mmHg should be considered.</li> <li>• In acute ischemic stroke, routine BP lowering with antihypertensive therapy is not recommended with the exceptions with the exceptions: in patients with acute ischemic stroke who are eligible for IV thrombolysis, BP should be carefully lowered and maintained at <math>&lt; 180/105</math> mmHg for at least the first 24 hours after thrombolysis; In patients with markedly elevated BP who do not receive fibrinolysis, drug therapy may be considered, based on clinical judgement, to reduce BP by 15% during the first 24 hours after the stroke onset.</li> <li>• In hypertensive patients with an acute cerebrovascular event, antihypertensive treatment is recommended immediately for transient ischemic attack (TIA) and after several days in ischemic stroke.</li> <li>• In all hypertensive patients with ischemic stroke or TIA, an SBP target range of 120 to 130 mmHg should be considered.</li> <li>• The recommended antihypertensive drug treatment strategy for stroke prevention is a RAS blocker plus a CCB or a thiazide-like diuretic.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with heart failure (HF) or left ventricular hypertrophy (LVH)</u></p> <ul style="list-style-type: none"> <li>• In hypertensive patients with heart failure (with reduced or preserved ejection fraction), BP-lowering treatment should be considered if <math>\geq 140/90</math> mmHg.</li> <li>• In patients with HFrEF, it is recommended that BP-lowering treatment comprises</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>an ACE inhibitor or ARB, and a beta-blocker and a diuretic and/or mineralocorticoid receptor antagonist (MRA) if required.</p> <ul style="list-style-type: none"> <li>• Dihydropyridine CCBs may be added if BP control is not achieved.</li> <li>• In patients with HFpEF, BP treatment threshold and target values should be the same as for HFrEF).</li> <li>• Because no specific drug has proven its superiority, all major agents can be used.</li> <li>• In all patients with LVH, it is recommended to treat with a RAS blocker or in combination with a CCB or diuretic and SBP should be lowered to a range of 120 to 130 mmHg.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• In patients with CAD receiving BP-lowering drugs, it is recommended to target SBP to <math>\leq 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg. In older patients, the target is an SBP range of 130 to 140 mmHg. The target DBP is <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• In hypertensive patients with a history of myocardial infarction, beta-blockers and RAS blockers are recommended as part of treatment.</li> <li>• In patients with asymptomatic angina, beta-blockers and/or CCBs are recommended.</li> </ul>
<p>National Institute for Health and Clinical Excellence: <b>Hypertension in adults: diagnosis and management (2019)</b><sup>15</sup></p>	<p><u>Choosing antihypertensive drug treatment (for people with or without type II diabetes)</u></p> <ul style="list-style-type: none"> <li>• Where possible, recommend treatment with drugs taken only once a day.</li> <li>• Prescribe non-proprietary drugs where these are appropriate and minimize cost.</li> <li>• Offer people with isolated systolic hypertension (systolic blood pressure <math>\geq 160</math> mmHg) the same treatment as people with both raised systolic and diastolic blood pressure.</li> <li>• Offer antihypertensive drug treatment to women of child-bearing potential with diagnosed hypertension in line with recommendations in this guideline. For women considering pregnancy or who are pregnant or breastfeeding, manage hypertension in line with the recommendations on Management of pregnancy with chronic hypertension and Breastfeeding in 'Hypertension in pregnancy'.</li> <li>• When choosing antihypertensive drug treatment for adults of black African or African-Caribbean family origin, consider an angiotensin II receptor blocker, in preference to an angiotensin-converting enzyme inhibitor.</li> </ul> <p><u>Step one treatment</u></p> <ul style="list-style-type: none"> <li>• Patients <math>&lt; 55</math> years of age should be offered a step one antihypertensive with an angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB).</li> <li>• Offer an ACE inhibitor or an ARB to adults starting step 1 antihypertensive treatment who have type II diabetes and are of any age or family origin or those aged <math>&lt; 55</math> years but not of black African or African-Caribbean family origin.</li> <li>• If an ACE inhibitor is not tolerated, offer an ARB.</li> <li>• Do not combine an ACE inhibitor with an ARB for the treatment of hypertension.</li> <li>• Offer a calcium channel blocker (CCB) to adults starting step 1 antihypertensive treatment who are <math>&gt; 55</math> years of age and do not have diabetes and are of black African or African-Caribbean family origin and do not have type II diabetes and of any age.</li> <li>• If a CCB is not suitable, for example because of edema or intolerance, or if there is evidence of heart failure or a high risk of heart failure, offer a thiazide-like diuretic.</li> <li>• If diuretic treatment is to be initiated or changed, offer a thiazide-like diuretic, such as indapamide in preference to a conventional thiazide diuretic such as</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>bendroflumethiazide or hydrochlorothiazide.</p> <ul style="list-style-type: none"> <li>• For adults with hypertension who are already receiving treatment with bendroflumethiazide or hydrochlorothiazide, who have stable, well-controlled blood pressure, continue with their treatment.</li> </ul> <p><u>Step two treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering next step treatment for hypertension discuss with the person if they are taking their medicine as prescribed and support adherence in line with NICE's guideline on “Medicines adherence: involving patients decisions about prescribed medicines and supporting adherence”.</li> <li>• If hypertension is not controlled with a step one treatment of an ACE inhibitor or ARB, offer choice of one of the following drugs in addition to the step one treatment: a CCB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults taking step one treatment of a CCB, offer the choice of one of the following drugs in addition to the step one treatment: an ACE inhibitor or an ARB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults of black African or African–Caribbean family origin who do not have type 2 diabetes taking step one treatment, consider an ARB, in preference to an ACE inhibitor, in addition to step one treatment.</li> </ul> <p><u>Step three treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering step three treatment, review the person’s medications to ensure they are being taken at the optimal doses and discuss adherence (see recommendation under step two).</li> <li>• If hypertension is not controlled in adults taking step two treatment, offer a combination of an ACE inhibitor or ARB and a CCB and a thiazide-like diuretic.</li> </ul> <p><u>Step four treatment</u></p> <ul style="list-style-type: none"> <li>• If hypertension is not controlled in adults taking the optimal tolerated doses of an ACE inhibitor or an ARB plus a CCB and a thiazide-like diuretic, regard them as having resistant hypertension.</li> <li>• Before considering further treatment for a person with resistant hypertension, confirm elevated clinic blood pressure measurements using ambulatory or home blood pressure recordings, assess for postural hypotension, and discuss adherence.</li> <li>• For people with confirmed resistant hypertension, consider adding a fourth antihypertensive drug as step four treatment or seeking specialist advice.</li> <li>• Consider further diuretic therapy with low-dose spironolactone for adults with resistant hypertension starting step four treatment who have a blood potassium level of 4.5 mmol/l or less. Use particular caution in people with a reduced estimated glomerular filtration rate because they have an increased risk of hyperkalemia.</li> <li>• When using further diuretic therapy for step four treatment of resistant hypertension, monitor blood sodium and potassium and renal function within one month of starting treatment and repeat as needed thereafter.</li> <li>• Consider an alpha-blocker or beta-blocker for adults with resistant hypertension starting step four treatment who have a blood potassium level of more than 4.5 mmol/l.</li> <li>• If blood pressure remains uncontrolled in people with resistant hypertension taking the optimal tolerated doses of four drugs, seek specialist advice.</li> </ul>
<p>International Society on Hypertension in Blacks: <b>Management of High Blood Pressure in</b></p>	<ul style="list-style-type: none"> <li>• To attain and maintain blood pressure (BP) below target levels, multiple antihypertensive drugs will be required in most hypertensive blacks.</li> <li>• Use of two-drug combination therapy when SBP is &gt;15 mm Hg and/or DBP is &gt;10 mm Hg above goal levels is increasingly recommended as first-line therapy.</li> <li>• Two-drug regimens have generally contained a thiazide-type diuretic; however,</li> </ul>

Clinical Guideline	Recommendation(s)
<p><b>Blacks (2010)<sup>16</sup></b></p>	<p>the combination of a calcium channel blocker (CCB) with either an ACE inhibitor or an ARB has been shown equally efficacious in BP lowering but with demonstrated superiority (CCB+ACE) for hard clinical outcomes compared with the same ACE inhibitor plus a thiazide-type diuretic.</p> <ul style="list-style-type: none"> <li>• In secondary prevention patients, the combination therapy should include a drug(s) with the appropriate compelling indications.</li> <li>• Certain classes of antihypertensive medications, specifically diuretics and CCBs, lower BP on average more than <math>\beta</math>-blockers and renin-angiotensin system (RAS) blockers in black patients when used as monotherapies.</li> <li>• In the absence of compelling indications, when BP is near goal levels, monotherapy with a diuretic or a CCB is preferred.</li> <li>• Lifestyle modifications should be initiated in all patients with hypertension, whether or not pharmacotherapy is planned.</li> <li>• ACE inhibitors or ARBs are recommended as alternative monotherapy options in the treatment of hypertension in blacks. The rationale for their lower tier monotherapy recommendation is because they have consistently achieved lesser average reductions in BP relative to that observed with monotherapy using either a diuretic or CCB.</li> </ul>
<p><b>Kidney Disease Improving Clinical Outcomes Group: KDIGO Clinical Practice Guideline for the Management of Blood Pressure in Chronic Kidney Disease (2021)<sup>17</sup></b></p>	<p><u>Blood pressure measurement</u></p> <ul style="list-style-type: none"> <li>• The Work Group recommends standardized office blood pressure (BP) measurement in preference to routine office BP measurements for the management of high BP in adults.</li> <li>• The Work Group suggests that out-of-office BP measurements with ambulatory BP monitoring (ABPM) or home BP monitoring (HBPM) be used to complement standardized office BP readings for the management of high BP.</li> </ul> <p><u>Lifestyle interventions for lowering BP in patients with chronic kidney disease (CKD) not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>• The Work Group suggests targeting a sodium intake &lt;2 grams of sodium per day (or &lt;90 mmol of sodium per day, or &lt;5 grams of sodium chloride per day) in patients with high BP and CKD.</li> <li>• The Work Group suggests that patients with high BP and CKD be advised to undertake moderate-intensity physical activity for a cumulative duration of at least 150 minutes per week, or to a level compatible with their cardiovascular and physical tolerance.</li> </ul> <p><u>BP management in patients with CKD, with or without diabetes, not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>• The Work Group suggests that adults with high BP and CKD be treated with a target systolic BP (SBP) of &lt;120 mmHg, when tolerated, using standardized office BP measurement.</li> <li>• The Work Group recommends starting renin-angiotensin-system inhibitors (RASi) (angiotensin-converting enzyme inhibitor [ACEi] or angiotensin II receptor blocker [ARB]) for people with high BP, CKD, and severely increased albuminuria without diabetes.</li> <li>• The Work Group suggests starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately increased albuminuria without diabetes.</li> <li>• The Work Group recommends starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately-to-severely increased albuminuria with diabetes.</li> <li>• The Work Group recommends avoiding any combination of ACEi, ARB, and direct renin inhibitor (DRI) therapy in patients with CKD, with or without diabetes.</li> </ul> <p><u>BP management in kidney transplant recipients</u></p> <ul style="list-style-type: none"> <li>• Treat adult kidney transplant recipients with high BP to a target BP of &lt;130</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>mmHg systolic and &lt;80 mmHg diastolic using standardized office BP measurement.</p> <ul style="list-style-type: none"> <li>The Work Group recommends that a dihydropyridine calcium channel blocker (CCB) or an ARB be used as the first-line antihypertensive agent in adult kidney transplant recipients.</li> </ul> <p><b>BP management in children with CKD</b></p> <ul style="list-style-type: none"> <li>The Work Group suggests that in children with CKD, 24-hour mean arterial pressure by ABPM should be lowered to &lt;50<sup>th</sup> percentile for age, sex, and height.</li> </ul>
<p>American College of Cardiology/ American Heart Association Task Force: <b>Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults (2017)</b><sup>18</sup></p>	<p><u>Initiation of Blood Pressure (BP) Treatment for Overall Cardiovascular Disease (CVD) Risk</u></p> <ul style="list-style-type: none"> <li>Use of BP-lowering medications is recommended for secondary prevention of recurrent CVD events in patients with clinical CVD and an average systolic blood pressure (SBP) <math>\geq 130</math> mmHg or an average diastolic blood pressure (DBP) of <math>\geq 80</math> mmHg and for primary prevention in adults with an estimated 10-year atherosclerotic cardiovascular disease (ASCVD) risk of <math>\geq 10\%</math> and an average SBP of <math>\geq 130</math> mmHg or an average <math>\geq 80</math> mmHg.</li> <li>Use of BP-lowering medication is recommended for primary prevention of CVD in adults with no history of CVD and with an estimated 10-year ASCVD risk <math>&lt; 10\%</math> and an SBP of <math>\geq 140</math> mmHg or a DBP of <math>\geq 90</math> mmHg.</li> <li>Simultaneous use of an angiotensin converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), and/or renin inhibitor is potentially harmful and is not recommended to treat adults with hypertension.</li> <li>For adults with confirmed hypertension and known CVD or 10-year ASCVD risk of <math>\geq 10\%</math>, a BP target <math>&lt; 130/80</math> mmHg is recommended. For adults with confirmed hypertension without additional markers of increased CVD risk, a BP target <math>&lt; 130/80</math> mmHg may be reasonable.</li> <li>For initiation of antihypertensive drug therapy, first-line agents include thiazide diuretics, calcium channel blockers (CCBs), and ACE inhibitors or ARBs.</li> <li>Initiation of antihypertensive drug therapy with two first-line agents of different classes, either as separate agents or in a fixed-dose combination, is recommended in adults with stage 2 hypertension and an average BP <math>&gt; 20/10</math> mmHg above their BP target.</li> <li>Initiation of antihypertensive drug therapy with a single antihypertensive drug is reasonable in adults with stage 1 hypertension and BP goal <math>&lt; 130/80</math> mmHg with dosage titration and sequential addition of other agents to achieve the BP target.</li> </ul> <p><u>Stable Ischemic Heart Disease (SIHD)</u></p> <ul style="list-style-type: none"> <li>In adults with SIHD and hypertension, a BP target <math>&lt; 130/80</math> is recommended.</li> <li>Adults with SIHD and hypertension (BP <math>\geq 130/80</math> mmHg) should be treated with medications [e.g., guideline-directed medical therapy (GDMT) beta-blockers, ACE inhibitors, or ARBs] for compelling indications [e.g., previous myocardial infarction (MI), stable angina] as first-line therapy, with the addition of other drugs (e.g., dihydropyridine CCBs, thiazide diuretics, and/or mineralocorticoid receptor antagonists) as needed to further control hypertension.</li> <li>In adults with SIHD with angina and persistent uncontrolled hypertension, the addition of dihydropyridine CCBs to GDMT beta-blockers is recommended.</li> <li>In adults who have had a MI or acute coronary syndrome, it is reasonable to continue GDMT beta-blockers beyond three years as long-term therapy for hypertension.</li> <li>Beta-blockers and/or CCBs might be considered to control hypertension in patients with coronary artery disease (CAD) had an MI more than three years ago and have angina.</li> </ul> <p><u>Heart Failure</u></p>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• In adults with increased risk of HF, the optimal BP in those with hypertension should be &lt;130 mmHg.</li> <li>• Adults with HFrEF and hypertension should be prescribed GDMT titrated to attain a BP &lt;130/80 mmHg.</li> <li>• Non-dihydropyridine CCBs are not recommended in the treatment of hypertension in adults with HFrEF.</li> <li>• In adults with HFpEF who present with symptoms of volume overload, diuretics should be prescribed to control hypertension.</li> <li>• Adults with HFpEF and persistent hypertension after management of volume overload should be prescribed ACE inhibitors or ARBs and beta-blockers titrated to attain SBP &lt;130 mmHg.</li> </ul> <p><u>CKD</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and CKD should be treated to a BP goal &lt;130/80 mmHg.</li> <li>• In adults with hypertension and CKD [stage 3 or higher or stage 1 or 2 with albuminuria (<math>\geq 300</math> mg/d, or <math>\geq 300</math> mg/g albumin-to-creatinine ratio or the equivalent in the first morning void)], treatment with an ACE inhibitor is reasonable to slow kidney disease progression. Treatment with an ARB may be reasonable if an ACE inhibitor is not tolerated.</li> <li>• After kidney transplantation, it is reasonable to treat patients with hypertension to a BP goal &lt;130/80 mmHg and with a CCB on the basis of improved glomerular filtration rate (GFR) and kidney survival.</li> </ul> <p><u>Cerebrovascular Disease</u></p> <ul style="list-style-type: none"> <li>• In adults with intracerebral hemorrhage (ICH) who present with SBP &gt;220 mmHg, it is reasonable to use continuous intravenous (IV) drug infusion and close BP monitoring to lower levels. Immediate lowering of SBP to &lt;140 mmHg in adults with spontaneous ICH who present within six hours of the acute event and have an SBP between 150 mmHg and 220 mmHg is not of benefit to reduce death or severe disability and can be potentially harmful.</li> <li>• Adults with acute ischemic stroke and elevated BP who are eligible for treatment with IV tissue plasminogen activator (tPA) should have their BP slowly lowered to &lt;185/110 mmHg before thrombolytic therapy is initiated.</li> <li>• In adults with an acute ischemic stroke, BP should be &lt;185/110 mmHg before administration of IV tPA and should be maintained below 180/105 mmHg for at least the first 24 hours after initiation drug therapy.</li> <li>• Starting or restarting antihypertensive therapy during hospitalization in patients with BP &gt;140/90 mmHg who are neurologically stable is safe and reasonable to improve long-term BP control, unless contraindicated.</li> <li>• In patient with BP <math>\geq 220/120</math> mmHg who did not receive IV alteplase or endovascular treatment and have no comorbid conditions requiring acute antihypertensive treatment, the benefit of initiating or reinitiating treatment of hypertension within the first 48 to 72 hours is uncertain. It might be reasonable to lower BP by 15% during the first 24 hours after onset of stroke. In patients with BP &lt;220/120 mmHg with the same conditions, initiating or reinitiating treatment of hypertension within the first 48 to 72 hours after an acute ischemic stroke is not effective to prevent death or dependency.</li> <li>• Adults with previously treated stroke or transient ischemic attack should be restarted on antihypertensive treatment after the first few days of the index event to reduce the risk of recurrent stroke and other vascular events. Treatment with a thiazide diuretic, ACE inhibitor, or ARB, or combination treatment consisting of a thiazide diuretic plus ACE inhibitor, is useful.</li> <li>• Adults not previously treated for hypertension who experienced a stroke or transient ischemic attack and have an established BP <math>\geq 140/90</math> mmHg should be</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>prescribed antihypertensive treatment a few days after the index event to reduce the risk of recurrent stroke and other vascular event.</p> <ul style="list-style-type: none"> <li>• For adults who experience a stroke or transient ischemic attack, selection of specific drugs should be individualized on the basis of patient comorbidities and agent pharmacological class.</li> <li>• For adults who experience a stroke or transient ischemic attack, a BP goal &lt;130/80 mmHg may be reasonable.</li> <li>• For adults with a lacunar stroke, a target SBP goal &lt;130 mmHg may be reasonable.</li> <li>• In adults previously untreated for hypertension who experience an ischemic stroke or transient ischemic attack and have an SBP &lt;140 mmHg and a DBP &lt;90 mmHg, the usefulness of initiating antihypertensive treatment is not well established.</li> </ul> <p><u>Peripheral Artery Disease (PAD)</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and PAD should be treated similarly to patients with hypertension without PAD.</li> </ul> <p><u>Diabetes Mellitus (DM)</u></p> <ul style="list-style-type: none"> <li>• In adults with DM and hypertension, antihypertensive drug treatment should be initiated at a BP of <math>\geq 130/80</math> mmHg with a treatment goal &lt;130/80 mmHg.</li> <li>• In adults with DM and hypertension, all first-line classes of antihypertensive agents (i.e., diuretics, ACE inhibitors, ARBs, and CCBs) are useful and effective.</li> <li>• In adults with DM and hypertension, ACE inhibitors or ARBs may be considered in the presence of albuminuria.</li> </ul> <p><u>Atrial Fibrillation, Valvular Heart Disease, and Aortic disease</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension can be useful for prevention of recurrence of AF.</li> <li>• In adults with asymptomatic aortic stenosis, hypertension should be treated with pharmacotherapy, starting at a low dose and gradually titrating upward as needed.</li> <li>• In patients with chronic aortic insufficiency, treatment of systolic hypertension with agents that do not slow the heart rate (i.e., avoid beta-blockers) is reasonable.</li> <li>• Beta-blockers are recommended as the preferred antihypertensive agents in patients with hypertension and thoracic aortic disease.</li> </ul> <p><u>Racial and Ethnic Differences in Treatment</u></p> <ul style="list-style-type: none"> <li>• In black adults with hypertension but without HF or CKD, including those with DM, initial antihypertensive treatment should include a thiazide-type diuretic or CCB. Two or more antihypertensive medications are recommended to achieve a BP target &lt;130/80 mmHg in most adults with hypertension, especially in black adults with hypertension.</li> </ul> <p><u>Pregnancy</u></p> <ul style="list-style-type: none"> <li>• Women with hypertension who become pregnant, or are planning to become pregnant, should be transitioned to methyldopa, nifedipine, and/or labetalol during pregnancy.</li> <li>• Women with hypertension who become pregnant should not be treated with ACE inhibitors, ARBs, or direct renin inhibitors.</li> </ul> <p><u>Older Persons</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension with an SBP treatment goal &lt;130 mmHg is recommended for noninstitutionalized ambulatory community-dwelling adults (<math>\geq 65</math> years of age) with an average SBP of <math>\geq 130</math> mmHg.</li> <li>• For older adults (<math>\geq 65</math> years of age) with hypertension and a higher burden of</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>comorbidity and limited life expectancy, clinical judgment, patient preference, and a team-based approach to assess risk/benefit is reasonable for decisions regarding intensity of BP lowering and choice of antihypertensive drugs.</p> <p><u>Hypertensive Crises</u></p> <ul style="list-style-type: none"> <li>• In adults with a hypertensive emergency, admission to an intensive care unit is recommended for continuous monitoring of BP and target organ damage and for parenteral administration of an appropriate agent.</li> <li>• For adults with a compelling condition (i.e., aortic dissection, severe pre-eclampsia or eclampsia, or pheochromocytoma crisis), SBP should be reduced to &lt;140 mmHg during the first hour and to &lt;120 mmHg in aortic dissection.</li> <li>• For adults without a compelling condition, SBP should be reduced by no more than 25% within the first hours; then, if stable, to 160/100 mmHg within the next two to six hours; and then cautiously to normal during the following 24 to 48 hours.</li> </ul> <p><u>Cognitive Decline and Dementia</u></p> <ul style="list-style-type: none"> <li>• In adults with hypertension, BP lowering is reasonable to prevent cognitive decline and dementia.</li> </ul> <p><u>Patients Undergoing Surgical Procedures</u></p> <ul style="list-style-type: none"> <li>• In patients with hypertension undergoing major surgery who have been on beta-blockers chronically, beta-blockers should be continued.</li> <li>• In patients with hypertension undergoing planned elective major surgery, it is reasonable to continue medical therapy for hypertension until surgery.</li> <li>• In patients with hypertension undergoing major surgery, discontinuation of ACE inhibitors or ARBs perioperatively may be considered.</li> <li>• In patients with planned elective major surgery and SBP <math>\geq</math>180 mmHg or DBP <math>\geq</math>110 mmHg, deferring surgery may be considered.</li> <li>• For patients undergoing surgery, abrupt pre-operative discontinuation of beta-blockers or clonidine is potentially harmful.</li> <li>• Beta-blockers should not be started on the day of surgery in beta-blocker-naïve patients.</li> <li>• Patients with intraoperative hypertension should be managed with IV medications until such time as oral medications can be resumed.</li> </ul>
<p>American Diabetes Association: <b>Standards of Medical Care in Diabetes (2022)</b><sup>19</sup></p>	<p><u>Hypertension/blood pressure control</u></p> <ul style="list-style-type: none"> <li>• Blood pressure should be measured at every routine visit. When possible, patients found to have elevated blood pressure (<math>\geq</math>140/90) should have blood pressure confirmed using multiple readings, including measurements on a separate day, to diagnose hypertension. Patients with blood pressure <math>\geq</math>180/110 and cardiovascular disease could be diagnosed with hypertension at a single visit.</li> <li>• All hypertensive patients with diabetes should monitor their blood pressure at home.</li> <li>• For patients with diabetes and hypertension, with diabetes and hypertension, blood pressure targets should be individualized through a shared decision-making process that addresses cardiovascular risk, potential adverse effects of antihypertensive medications, and patient preferences.</li> <li>• For individuals with diabetes and hypertension at higher cardiovascular risk (existing atherosclerotic cardiovascular disease [ASCVD] or 10-year ASCVD risk <math>\geq</math>15%), a blood pressure target of &lt;130/80 mmHg may be appropriate, if it can be safely attained.</li> <li>• For individuals with diabetes and hypertension at lower risk for cardiovascular disease (10-year atherosclerotic cardiovascular disease risk &lt;15%), treat to blood pressure target of &lt;140/90.</li> <li>• In pregnant patients with diabetes and preexisting hypertension, a blood pressure</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>target of 110 to 135/85 is suggested in the interest of reducing the risk for accelerated maternal hypertension and minimizing impaired fetal growth.</p> <ul style="list-style-type: none"> <li>• For patients with blood pressure &gt;120/80, lifestyle intervention consists of weight loss when indicated, a Dietary Approaches to Stop Hypertension (DASH)-style eating pattern including reducing sodium and increasing potassium intake, moderation of alcohol intake, and increased physical activity.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq</math>140/90 mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of pharmacologic therapy to achieve blood pressure goals.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq</math>160/100 mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of two drugs or a single pill combination of drugs demonstrated to reduce cardiovascular events in patients with diabetes.</li> <li>• Treatment for hypertension should include drug classes demonstrated to reduce cardiovascular events in patients with diabetes (ACE inhibitors, angiotensin receptor blockers, thiazide-like diuretics, or dihydropyridine calcium channel blockers). ACE inhibitors or angiotensin receptor blockers are recommended first-line therapy for hypertension in people with diabetes and coronary artery disease.</li> <li>• Multiple-drug therapy is generally required to achieve blood pressure targets (but not a combination of ACE inhibitors and angiotensin receptor blockers).</li> <li>• An ACE inhibitor or angiotensin receptor blocker, at the maximum tolerated dose indicated for blood pressure treatment, is the recommended first-line treatment for hypertension in patients with diabetes and urinary albumin-to-creatinine ratio <math>\geq</math>300 mg/g creatinine or 30 to 299 mg/g creatinine. If one class is not tolerated, the other should be substituted.</li> <li>• For patients treated with an ACE inhibitor, angiotensin receptor blocker, or diuretic, serum creatinine/estimated glomerular filtration rate and serum potassium levels should be monitored at least annually.</li> <li>• Patients with hypertension who are not meeting blood pressure targets on three classes of antihypertensive medications (including a diuretic) should be considered for mineralocorticoid receptor antagonist therapy.</li> </ul> <p><b>Chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>• At least once a year, assess urinary albumin (e.g., spot urinary albumin-to-creatinine ratio) and estimated glomerular filtration rate in patients with type 1 diabetes with duration of five or more years and in all patients with type 2 diabetes.</li> <li>• Patients with diabetes and urinary albumin <math>\geq</math>300 mg/g creatinine and/ or an estimated glomerular filtration rate 30 to 60 mL/min/1.73 m<sup>2</sup> should be monitored twice annually to guide therapy.</li> <li>• Optimize glucose control to reduce the risk or slow the progression of chronic kidney disease (CKD).</li> <li>• For patients with type 2 diabetes and diabetic kidney disease, use of a sodium-glucose cotransporter 2 inhibitor in patients with an estimated glomerular filtration rate <math>\geq</math>25 mL/min/1.73 m<sup>2</sup> and urinary albumin <math>\geq</math>300 mg/g creatinine is recommended to reduce CKD progression and cardiovascular events.</li> <li>• In patients with type 2 diabetes and CKD, consider use of sodium-glucose cotransporter 2 inhibitors additionally for cardiovascular risk reduction when estimated glomerular filtration rate and urinary albumin creatinine are <math>\geq</math>25 mL/min/1.73 m<sup>2</sup> or <math>\geq</math>300 mg/g, respectively.</li> <li>• In patients with CKD who are at increased risk for cardiovascular events or CKD progression and are unable to use a sodium-glucose cotransporter 2 inhibitor, a nonsteroidal mineralocorticoid receptor antagonist (finerenone) is recommended to reduce CKD progression and cardiovascular events.</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• Optimize blood pressure control and reduce blood pressure variability to reduce the risk or slow the progression of CKD.</li> <li>• Do not discontinue renin-angiotensin system blockade for minor increases in serum creatinine (<math>\leq 30\%</math>) in the absence of volume depletion.</li> <li>• For people with nondialysis-dependent stage 3 or higher CKD, dietary protein intake should be a maximum of 0.8 g/kg body weight per day (the recommended daily allowance). For patients on dialysis, higher levels of dietary protein intake should be considered, since malnutrition is a major problem in some dialysis patients.</li> <li>• In nonpregnant patients with diabetes and hypertension, either an ACE inhibitor or an angiotensin receptor blocker is recommended for those with modestly elevated urinary albumin-to-creatinine ratio (30 to 299 mg/g creatinine) and is strongly recommended for those with urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine and/or estimated glomerular filtration rate <math>&lt; 60</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Periodically monitor serum creatinine and potassium levels for the development of increased creatinine or changes in potassium when ACE inhibitors, angiotensin receptor blockers, or diuretics are used.</li> <li>• An ACE inhibitor or an angiotensin receptor blocker is not recommended for the primary prevention of CKD in patients with diabetes who have normal blood pressure, normal urinary albumin-to-creatinine ratio (<math>&lt; 30</math> mg/g creatinine), and normal estimated glomerular filtration rate.</li> <li>• Patients should be referred for evaluation by a nephrologist if they have an estimated glomerular filtration rate <math>&lt; 30</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Promptly refer to a nephrologist for uncertainty about the etiology of kidney disease, difficult management issues, and rapidly progressing kidney disease.</li> </ul>
<p>American Association for the Study of Liver Diseases: <b>Diagnosis, Evaluation, and Management of Ascites, Spontaneous Bacterial Peritonitis and Hepatorenal Syndrome: 2021 Practice Guidance (2021)</b><sup>20</sup></p>	<p><u>Treatment of ascites</u></p> <ul style="list-style-type: none"> <li>• Moderate sodium restriction (2 g or 90 mmol/day) and diuretics (spironolactone with or without furosemide) are the first-line treatment in patients with cirrhosis and grade 2 ascites.</li> <li>• After ascites is adequately mobilized, attempts should be made to taper the diuretics to the lowest dose necessary to maintain minimal or no ascites to prevent the development of adverse effects.</li> <li>• Fluid restriction is not necessary unless serum sodium is <math>&lt; 125</math> mmol/L.</li> <li>• In patients receiving diuretics, body weight and serum creatinine and sodium should be regularly monitored to assess response and to detect the development of adverse effects.</li> <li>• Human albumin solution (20 to 40 g/week) or baclofen administration (10 mg/day, with a weekly increase of 10 mg/day, up to 30 mg/day) can be considered in cases of severe muscle cramps.</li> <li>• Large-volume paracentesis is the first-line treatment of grade 3 ascites. After paracentesis, sodium restriction and diuretics should be started.</li> <li>• Referral for liver transplant evaluation should be considered in patients with grade 2 or 3 ascites.</li> <li>• Nonsteroidal anti-inflammatory drugs, angiotensin-converting enzyme inhibitors, and angiotensin receptor blockers should be avoided in patients with cirrhosis and ascites.</li> <li>• Aminoglycosides should be avoided whenever possible in the treatment of bacterial infections.</li> <li>• For patients with cirrhosis and diuretic-responsive ascites, controversial data suggest potential benefits of long-term infusion of human albumin solution. At present, no recommendation can be made for its use in routine clinical practice.</li> </ul>

### III. Indications

The Food and Drug Administration (FDA)-approved indications for the loop diuretics are noted in Table 3. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 3. FDA-Approved Indications for the Loop Diuretics<sup>3-6</sup>**

Indication	Bumetanide	Ethacrynic Acid	Furosemide	Torsemide
<b>Edema</b>				
Adjunctive therapy in acute pulmonary edema			✓* (injection)	
Treatment of edema associated with congestive heart failure, hepatic disease, and renal disease	✓ †	✓ ‡	✓ §	✓
Rapid onset of diuresis is desired (e.g., in acute pulmonary edema) or when gastrointestinal absorption is impaired or oral therapy is not practical				✓ (injection)
Short-term management of ascites due to malignancy, idiopathic edema, and lymphedema		✓		
Short-term management of hospitalized pediatric patients, other than infants, with congenital heart disease or nephrotic syndrome		✓		
<b>Hypertension</b>				
Treatment of hypertension			✓    ¶	✓

\*The intravenous administration of furosemide is indicated when a rapid onset of diuresis is desired.

†If impaired gastrointestinal absorption is suspected or oral administration is not practical, bumetanide should be given by the intramuscular or intravenous route.

‡Treatment of edema when an agent with greater diuretic potential than those commonly employed is required.

§If impaired gastrointestinal absorption is suspected or oral administration is not practical, furosemide should be given by the intramuscular or intravenous route.

|| Alone or in combination with other antihypertensive agents.

¶If impaired gastrointestinal absorption is suspected or oral administration is not practical, furosemide should be given by the intramuscular or intravenous route.

### IV. Pharmacokinetics

The pharmacokinetic parameters of the loop diuretics are listed in Table 4.

**Table 4. Pharmacokinetic Parameters of the Loop Diuretics<sup>7</sup>**

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life (hours)
Bumetanide	80 to 95	90 to 99	Liver, partial (% not reported)	Bile (2) Feces (10 to 20) Renal (50 to 81)	1 to 1.5
Ethacrynic acid	100	90	Liver (% not reported)	Renal (66)	1 to 4
Furosemide	47 to 70	91 to 99	Liver (10)	Feces (7 to 9) Renal (60 to 90)	0.5 to 2
Torsemide	80 to 90	99	Liver (80)	Renal (69)	3 to 6

### V. Drug Interactions

Major drug interactions with the loop diuretics are listed in Table 5.

**Table 5. Major Drug Interactions with the Loop Diuretics<sup>7</sup>**

Generic Name(s)	Interaction	Mechanism
Loop diuretics (bumetanide, ethacrynic acid, furosemide, torsemide)	Desmopressin	Concomitant use of desmopressin nasal spray and a loop diuretic is contraindicated due to an increased risk of severe hyponatremia.
Loop diuretics (bumetanide, ethacrynic acid, furosemide, torsemide)	Cisapride	Possible additive prolongation of the QT interval due to electrolyte loss increases the risk of life-threatening cardiac arrhythmias, including torsades de pointes.
Loop diuretics (bumetanide, ethacrynic acid, furosemide)	Digitalis Glycosides	Diuretic-induced electrolyte disturbances may predispose patients to digitalis-induced arrhythmias.
Loop diuretics (ethacrynic acid, furosemide, torsemide)	Aminoglycosides	Auditory toxicity may be increased by possible synergistic activity. The mechanism is unknown.
Loop diuretics (bumetanide, ethacrynic acid, furosemide, torsemide)	Cisplatin	The combination of loop diuretics and cisplatin may cause additive ototoxicity through an unknown mechanism.
Loop diuretics (bumetanide, ethacrynic acid, furosemide, torsemide)	Lithium	Increased plasma lithium concentrations increase risk of toxicity. The mechanism is unknown.
Loop diuretics (bumetanide, ethacrynic acid, furosemide, torsemide)	Thiazide diuretics	The two classes of agents exhibit their diuretic action at different sites in the renal tubules and have synergistic effects that may result in profound diuresis and serious electrolyte abnormalities.
Loop diuretics (bumetanide, ethacrynic acid, furosemide, torsemide)	Dofetilide	Concurrent use of dofetilide and diuretics may result in an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest).
Loop diuretics (bumetanide, ethacrynic acid, furosemide, torsemide)	Sotalol	Concurrent use of sotalol and diuretics may result in an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest).
Loop diuretics (bumetanide)	Indomethacin	Concurrent use of bumetanide and indomethacin may result in reduced diuretic effectiveness and possible nephrotoxicity.

## VI. Adverse Drug Events

The most common adverse drug events reported with the loop diuretics are listed in Table 6. The boxed warning for the loop diuretics is listed in Table 7.

**Table 6. Adverse Drug Events (%) Reported with the Loop Diuretics<sup>3-7</sup>**

Adverse Events	Bumetanide	Ethacrynic Acid	Furosemide	Torsemide

**Table 7. Boxed Warning for Bumetanide and Furosemide<sup>6</sup>**

<b>WARNING</b>
Loop diuretics are potent diuretics which, if given in excessive amounts, can lead to a profound diuresis with water and electrolyte depletion. Therefore, careful medical supervision is required and dose and dosage schedule have to be adjusted to the individual patient's needs.

## VII. Dosing and Administration

The usual dosing regimens for the loop diuretics are listed in Table 8.

**Table 8. Usual Dosing Regimens for the Loop Diuretics<sup>3-7</sup>**

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
Bumetanide	<u>Edema:</u> Injection: 0.5 to 1 mg over one minute; maximum, 10 mg/day  Tablet: 0.5 to 2 mg/day; maximum, 10 mg/day	Safety and efficacy in children have not been established.	Injection: 0.25 mg/mL  Tablet: 0.5 mg 1 mg 2 mg
Ethacrynic acid	<u>Edema:</u> Tablet: 50 to 200 mg/day	<u>Edema (13 months and older):</u> Tablet: initial, 25 mg	Tablet: 25 mg
Furosemide	<u>Edema:</u> Injection (acute pulmonary edema): 40 mg intravenously over 1 to 2 minutes; maintenance, may increase to 80 mg intravenously  Injection: 20 to 40 mg as a single intravenous or intramuscular injection; maintenance, may repeat in two hours or increased by 20 mg until desired response	<u>Edema:</u> Injection: initial, 1 mg/kg; maintenance, may increase by 1 mg/kg not sooner than two hours after the previous dose; maximum, 6 mg/kg per dose  Solution, tablet: 2 mg/kg as a single dose; maximum, 6 mg/kg per dose	Injection: 10 mg/mL  Solution: 10 mg/mL 40 mg/5 mL  Tablet: 20 mg 40 mg 80 mg

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
	<p>Oral: 20 to 80 mg/days; maximum, 600 mg/day</p> <p><u>Hypertension:</u> Injection, solution, tablet: 80 mg/day</p>		
Toremide	<p><u>Edema:</u> Injection, tablet (chronic renal failure): initial, 20 mg once daily; maintenance, 200 mg/day</p> <p>Injection, tablet (congestive heart failure): initial, 10 to 20 mg once daily; maximum, 200 mg/day</p> <p>Injection, tablet (hepatic cirrhosis): initial, 5 to 10 mg once daily; maximum, 40 mg/day</p> <p><u>Hypertension:</u> Injection, tablet: initial, 5 to 10 mg/day; maximum, 10 mg/day</p>	Safety and efficacy in children have not been established.	Tablet: 5 mg 10 mg 20 mg 100 mg

## VIII. Effectiveness

Clinical studies evaluating the safety and efficacy of the loop diuretics are summarized in Table 9.

**Table 9. Comparative Clinical Trials with the Loop Diuretics**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<b>Cirrhosis</b>				
Laffi et al. <sup>21</sup> (1991)  Furosemide 25 mg/day  vs  torasemide* 10 mg/day	DB, RCT  Nonazotemic cirrhotic patients with ascites	N=24  3 days	Primary: Percent increase in natriuresis, body weight loss, percent increase in diuresis, plasma aldosterone concentration, plasma renin activity  Secondary: Not reported	Primary: Treatment with torasemide led to significantly greater natriuresis than furosemide (P<0.02). There was a greater percentage increase in basal values (day 1: 130 vs 50%; day 2: 104 vs 42%; and day 3: 65 vs 26%, respectively).  Body weight loss was significantly higher with torasemide (2.5 kg) than with furosemide (1.3 kg; P<0.02).  There was no significant difference (P=0.08) in the percent increase in diuresis among the treatment groups (day 1: 60 vs 26%; day 2: 35 vs 27%; day 3: 31 vs 24%).  Plasma aldosterone concentrations (ng/mL) with torasemide were 0.79 and 0.94 at baseline and day three, respectively. Plasma aldosterone concentrations with furosemide were 0.54 and 0.52 at baseline and day three, respectively.  Plasma renin activity (ng/mL/hr) with torasemide were 5.8 and 9.4 at baseline and day three, respectively. Plasma renin activity with furosemide were 4.2 and 5.4 at baseline and day three, respectively.  Secondary: Not reported
Gerbes et al. <sup>22</sup> (1993)  Furosemide 80 mg as a single dose  vs	DB, RCT, XO  Patients with cirrhosis and ascites	N=28  24 hours	Primary: Urine volume, urine sodium volume, urine potassium volume, plasma aldosterone concentration,	Primary: Treatment with torasemide led to greater cumulative 24 hour diuresis than furosemide (2,863 vs 2,111; P<0.05).  There was no difference in cumulative 0 to 6 hour sodium excretion with torasemide or furosemide (95.7 vs 92.1 mmol, respectively; P value not significant). There was greater cumulative 6 to 24 hour sodium excretion

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>torasemide* 20 mg as a single dose</p>			<p>plasma renin activity</p> <p>Secondary: Not reported</p>	<p>with torasemide compared to furosemide (38.4 vs 16.6 mmol; P&lt;0.05). There was no difference in cumulative 0 to 24 hour sodium excretion with torasemide or furosemide (134.0 vs 108.5 mmol, respectively; P value not significant).</p> <p>There was no difference in cumulative 0 to 6 hour potassium excretion with torasemide or furosemide (57.5 vs 39.9 mmol, respectively; P value not significant). There was greater cumulative 6 to 24 hour potassium excretion with torasemide compared to furosemide (36.0 vs 27.6 mmol; P&lt;0.05). There was no difference in cumulative 0 to 24 hour potassium excretion with torasemide or furosemide (88.3 vs 68.0 mmol, respectively; P value not significant).</p> <p>Plasma aldosterone concentrations (ng/100 mL) with torasemide were 111.9 and 132 at baseline and 24 hours, respectively. Plasma aldosterone concentrations with furosemide were 105.7 and 131 at baseline and 24 hours, respectively.</p> <p>Plasma renin activity (ng/mL/hr) with torasemide were 29.9 and 30.6 at baseline and 24 hours, respectively. Plasma renin activity with furosemide were 34.7 and 36.8 at baseline and 24 hours, respectively.</p> <p>Secondary: Not reported</p>
<p>Fiaccadori et al.<sup>23</sup> (1993)</p> <p>Furosemide 50 mg/day</p> <p>vs</p> <p>torasemide* 20 mg/day</p> <p>Patients also received</p>	<p>DB, RCT</p> <p>Nonazotemic cirrhotic patients with controlled ascites</p>	<p>N=28</p> <p>10 weeks</p>	<p>Primary: Excretion of phosphate, free water, sodium, potassium, calcium, and uric acid</p> <p>Secondary: Not reported</p>	<p>Primary: Furosemide produced more excretion of phosphates (P&lt;0.001) and magnesium (P&lt;0.05) compared to torasemide.</p> <p>Torasemide produced more excretion of free water (P&lt;0.02).</p> <p>There was no difference in the excretion of sodium, potassium, calcium, or uric acid among the treatment groups.</p> <p>Secondary: Not reported</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
spironolactone 200 mg/day				
Abecasis et al. <sup>24</sup> (2001)  Frusemide† 40 mg/day  vs  torsemide 20 mg/day  Patients also received spironolactone 200 mg/day	OL, RCT  Cirrhotic patients with ascites	N=46  11 to 12 days	Primary: Resolution of ascites, weight loss, diuretic dosage, diuretic response  Secondary: Not reported	Primary: There was no difference in the percentages of patients with resolution of ascites with torsemide compared to frusemide (73 vs 75%; P value not significant).  There was no difference in weight loss with torsemide compared to frusemide (8 vs 8.5 kg; P value not significant).  More patients receiving frusemide required an increase in diuretic dosage (37.5%) than with torsemide (9%; P<0.05).  Torsemide produced a greater diuretic response in 24 hours than frusemide (P<0.007).
<b>Heart Failure/Edema</b>				
Galløe et al. <sup>25</sup> (2006)  Bumetanide 0.5 mg (0, 1, 2 or 4 tablets BID) plus trandolapril 0.5 mg (0, 1, 2 or 4 tablets QD)  Treatment was combined to achieve 16 different dosage combinations.	DB, DD, RCT, multiple XO  Patients with previous MI ≥3 years ago, had medical treatment for heart failure and ejection fraction between 0.36 and 0.54 estimated by echocardiography	N=16  14 days	Primary: Patient reported quality of life  Secondary: Effects on kidney function, left ventricular function and blood pressure	Primary: Bumetanide 0.5 mg-treated patients experienced a 12% increase in well-being, but higher doses of bumetanide decreased patient's well-being by 12% compared to placebo (P<0.002). Increasing doses of bumetanide tended to increase tiredness (P=0.072). There were no significant effects of bumetanide therapy on the patients' opinion of their health, degree of dyspnea, appetite or work capacity.  Secondary: Bumetanide therapy increased 24 hour urine production in a straight dose-dependent manner (P<0.0001), while trandolapril therapy had no effect (P=0.53). Bumetanide and trandolapril therapy did not alter the 24 hour creatinine excretion and creatinine clearance (P=0.33, P=0.11 and P=0.53, P=0.97, respectively).  Bumetanide therapy decreased left ventricular function and increased heart rate in a dose-dependent manner (P<0.001). Left ventricular function was also nonsignificantly decreased with trandolapril therapy (P>0.062).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				Trandolapril therapy significantly reduced SBP by maximally of 7.6 mm Hg (5.8%) with the lowest dose of 0.5 mg/day (P=0.007). Bumetanide therapy had no significant effect on DBP (P=0.23).
Hutcheon et al. <sup>26</sup> (1981)  Bumetanide 1 to 2 mg/day  vs  furosemide 80 mg/day	DB, PG  Patients with severe edema associated with CHF	N=20  3 days	Primary: Edema, symptoms of heart failure, safety and tolerability  Secondary: Not reported	Primary: Each agent was effective in decreasing the edema and relieving the symptoms of heart failure.  Side effects were not severe and were similar in both treatment groups. Muscle cramps and abdominal pain were deemed not severe. Electrolyte shifts indicative of hypochloremic alkalosis and hyponatremia were seen in two patients in the bumetanide group.  Secondary: Not reported
Konecke et al. <sup>27</sup> (1981)  Bumetanide  vs  furosemide  No dose or frequency reported.	OL, PG, RCT  Men and women with clinically detectable edema and signs and symptoms of CHF (e.g., rales, gallop rhythm, orthopnea, dyspnea, engorged neck veins, paroxysmal nocturnal dyspnea, congested liver, etc.)	N=42  6 months	Primary: Changes in weight, blood pressure, pulse, signs and symptoms of CHF, electrolytes and functional capacity, safety and tolerability  Secondary: Not reported	Primary: There were no statistical differences in changes in body weight, blood pressure, edema, abdominal girth, and hepatomegaly and other signs and symptoms of CHF in patients receiving bumetanide vs furosemide.  There were variable minor changes in serum sodium, potassium, chloride, and uric acid in both groups throughout the treatment. Changes remained within normal limits and reached significance for chloride at weeks eight and 16 in the bumetanide group.  Functional capacity improved slightly or remained unchanged throughout treatment in both treatment groups.  There were no major side effects that were medication related in both treatment groups.  Secondary: Not reported
Nicholson et al. <sup>28</sup> (1977)  Bumetanide 1 mg/day alternating	RCT, XO  Patients with cirrhosis and fluid overload	N=10  6 months	Primary: Ascites and edema  Secondary: Adverse events	Primary: Bumetanide and frusemide were both effective in controlling ascites and edema, with nine out of 10 patients showing a satisfactory response.  Secondary:

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>with 3 mg/day for 3 months</p> <p>vs</p> <p>frusemide† 40 mg/day alternating with 160 mg/day for 3 months</p>				<p>Side effects were reported in six patients. The most common side effects were urinary frequency and nocturia, which occurred in four patients taking bumetanide and 1 patient taking frusemide. There was one patient on bumetanide and one patient on frusemide who developed symptoms of postural hypotension.</p>
<p>Eshaghian et al.<sup>29</sup> (2006)</p> <p>Furosemide 0 to 40 mg/day (group 1)</p> <p>vs</p> <p>furosemide 41 to 80 mg/day (group 2)</p> <p>vs</p> <p>furosemide 81 to 160 mg/day (group 3)</p> <p>vs</p> <p>furosemide &gt;160 mg/day (group 4)</p>	<p>Cohort</p> <p>Men and women with advanced systolic heart failure referred to a single university medical center for heart failure management and/or transplant evaluation from 1985 to 2004</p>	<p>N=1,354</p> <p>2 years</p>	<p>Primary: All-cause mortality</p> <p>Secondary: Composite endpoint of death or urgent transplant</p>	<p>Primary: There were 269 deaths during the two year follow-up, with 182 deaths by year one and 87 deaths during year two. Of the 269 deaths, 91 deaths were due to progressive heart failure, 72 deaths were sudden, eight deaths were secondary to myocardial infarction and 101 were unknown.</p> <p>Survival estimates at one year were 91, 88, 80, and 69% for groups 1, 2, 3, and 4, respectively (P&lt;0.0001). Survival estimates at two years were 83, 81, 68, and 53%, respectively (P&lt;0.0001).</p> <p>Secondary: There were a total of 431 patients who received heart transplants by the end of the two year follow up: 223 urgent and 208 elective.</p> <p>The HRs for death from any cause, death and urgent transplantation, death from progressive heart failure, and sudden death for group 4 compared with group 1 were similar.</p> <p>On univariate analysis, compared with group 1, increasing loop diuretic dose were associated with a progressive increase in mortality (group 2: HR, 1.2; 95% CI, 0.8 to 1.7, group 3: HR, 2.1; 95% CI, 1.5 to 2.9, and group 4: HR, 3.4; 95% CI, 2.4 to 4.7).</p>
<p>Mentz et al.<sup>30</sup> (2016)</p> <p>ASCEND-HF</p> <p>Furosemide</p>	<p>Cohort analysis of ASCEND-HF (diuretic choice not randomized)</p> <p>Patients enrolled in</p>	<p>N=4,177</p>	<p>Primary: All-cause mortality or HF hospitalization through 30-days after discharge</p>	<p>Primary &amp; Secondary: Of the 4,177 patients in the outcomes analysis cohort, 87% (n=3,620) received furosemide and 13% (n=557) received torsemide. Torsemide was associated with similar outcomes on unadjusted analysis (30-day mortality/HF hospitalization OR, 1.03; 95% CI, 0.73 to 1.45, P=0.88 and 180-day mortality HR, 0.97; 95% CI, 0.73 to 1.29; P=0.83). On inverse</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs torsemide	the ASCEND-HF Trial (patients with acute HF) discharged alive on either furosemide or torsemide		Secondary: 30-day all-cause mortality, 30-day HF hospitalization and 180-day all-cause mortality post-discharge	propensity weighted-adjusted analysis, torsemide use was associated with nominally lower 30-day mortality or HF hospitalization (OR, 0.89; 95% CI, 0.62 to 1.29; P=0.55), 30-day mortality (OR, 0.89; 95% CI, 0.40 to 1.97; P=0.78), 30-day HF hospitalization (OR, 0.87; 95% CI, 0.58 to 1.30; P=0.49) and 180-day mortality (HR, 0.86; 95% CI, 0.63 to 1.19; P=0.37) compared with furosemide.
Murray et al. <sup>31</sup> (2001)  Furosemide  vs  torsemide	OL, RCT  Patients with CHF	N=234  12 months	Primary: Readmission to the hospital for heart failure  Secondary: Readmission for all cardiovascular causes and for all causes, numbers of hospital days, health-related quality of life	Primary: Patients receiving torsemide were less likely to need readmission for heart failure (32%) compared to furosemide (17%; P<0.01).  Secondary: Patients receiving torsemide were less likely to need readmission for all cardiovascular causes (59%) compared to furosemide (44%; P=0.03).  There was no difference in the rate of admissions for all causes among the treatment groups (76 vs 71%; P=0.36).  Patients treated with torsemide had significantly fewer hospital days for heart failure (106 vs 296 days; P=0.02).  Improvements in fatigue scores from baseline were significantly greater among patients treated with torsemide compared to furosemide at months 2, 8, and 12 (P<0.05).
Cosín et al. <sup>32</sup> (2002)  Furosemide 40 mg/day orally or other diuretics  vs  torasemide* 10 mg/day orally	OL  Patients with NYHA functional class II to III heart failure	N=1,377  12 months	Primary: Mortality, morbidity, functional class and serum potassium levels (<3.5 or >5 mEq/L)  Secondary: Not reported	Primary: Total mortality was significantly lower in the torasemide group (2.2%) compared to the furosemide/other diuretics group (4.5%; P<0.05).  Cardiac mortality was lower in patients receiving torasemide (1.4%) than in those receiving furosemide/other diuretics (3.5%; P<0.05).  NYHA improvement in at least 1 class occurred in more patients who received torasemide (45.8%) than those who received furosemide/other diuretics (37.2%; P=0.00017).  Abnormal potassium levels were observed in fewer torasemide patients

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				(12.9%) than furosemide/other diuretics patients (17.9%; P=0.013).
Muller et al. <sup>33</sup> (2003)  Furosemide  vs  torasemide*	R, OL  Patients with NYHA functional class II-IV congestive heart failure	N=237  9 months	Primary: Clinical improvement in heart failure, quality of life, hospitalizations, safety and tolerability  Secondary: Not reported	Primary: Clinical improvement in chronic heart failure was seen in both groups, but the trend to improve by at least one NYHA class was significant with torasemide (P=0.014) compared to furosemide-treated patients.  There were no differences in adverse reactions and hospitalizations due to CHF.  Secondary: Not reported
Kasama et al. <sup>34</sup> (2006)  Furosemide 20 to 40 mg/day  vs  torasemide* 4 to 8 mg/day	RCT  Patients with non-ischemic CHF (LVEF <45%) also being treated with an ACE inhibitor	N=40  6 months	Primary: Effect on cardiac sympathetic nerve activity (delayed heart to mediastinum count ratio, delayed total defect score, washout rate)  Secondary: Effect on left ventricular remodeling (left ventricular end diastolic volume, left ventricular end systolic volume)	Primary: In the furosemide group at the end of treatment, mean heart to mediastinum count ratio increased from 1.68±0.18 to 1.71±0.19 (P value not significant), mean total defect score decreased from 42±11 to 40±12 (P value not significant), and mean washout rate decreased from 50±8% to 47±12% (P value not significant).  In the torasemide group at the end of treatment, mean heart to mediastinum count ratio increased from 1.61±0.19 to 1.77±0.24 (P<0.001), mean total defect score decreased from 44±8 to 36±8 (P<0.001), and mean washout rate decreased from 52±12 to 41±14% (P=0.001).  Secondary: In the furosemide group left ventricular end diastolic volume decreased from 174±24 to 165±34 mL (P value not significant), left ventricular end systolic volume decreased from 120±15 to 109±33 mL (P value not significant), and LVEF increased from 31±7 to 32±7% (P value not significant).  In the torasemide group left ventricular end diastolic volume decreased from 173±22 to 147±30 mL (P<0.01), left ventricular end systolic volume decreased from 117±19 to 95±25 mL (P<0.001), and LVE increased from 31±7 to 34±7% (P value not significant).

(replacement group) was converted from furosemide dosage using 0.2 mg torasemide* corresponding to 1 mg furosemide	CHF or previously treated with furosemide		levels, and adverse events	natriuretic peptide and aldosterone levels (P<0.05); however, plasma rennin activity was not significantly decreased among both groups.  Serum potassium levels were significantly increased in the replacement group (P<0.05), but not in the de novo group.  The most commonly reported adverse events of torasemide were those associated with loop diuretics in general.
Faris et al. <sup>39</sup> (2006)  Loop diuretics (furosemide, bumetanide), thiazide diuretics (chlorothiazide), or potassium-sparing diuretics (amiloride, triamterene)  vs  placebo or active control (ACE inhibitors, digoxin)	MA  Adult patients with chronic heart failure	N=525 (14 trials)  2 to 52 weeks	Primary: Mortality  Secondary: Effect of diuretic withdrawal on worsening of heart failure and exercise capacity	Primary: Mortality was reported in three of the seven placebo-controlled trials, and this analysis showed that mortality was lower for patients treated with diuretics than with placebo (3/111 [2.7%] vs 12/110 [10.9%], respectively; OR, 0.24; 95% CI, 0.07 to 0.83; P=0.02).  These results showed that patients treated with diuretics had an absolute risk reduction of 8% when compared to placebo and a number needed to treat of 12.5.  Secondary: An analysis of pooled data from two trials showed lower admission rates for worsening heart failure in patients taking diuretics than in patients taking placebo (OR, 0.07; 95% CI, 0.01 to 0.52; P=0.01).  Diuretics were found to improve exercise capacity, with a difference in means of 0.74 (95% CI, 0.37 to 1.11; P<0.0001) and of 0.67 (95% CI, 0.02 to 1.31; P=0.04.), respectively. The combined results of these 4 trials indicated that diuretics improved exercise capacity in participants with chronic heart failure with a difference in means of 0.72 (95% CI, 0.40 to 1.04; P<0.0001).
<b>Hypertension</b>				
Van der Heijden et al. <sup>40</sup> (1998)  Bumetanide 1 mg/day for 6 weeks	DB, PC, XO  Patients with HTN	N=27  24 weeks	Primary: Changes in blood pressure, serum lipid levels, lab values, safety and tolerability	Primary: Bumetanide and furosemide reduced SBP by 8.2% (P<0.0002) and DBP by 4.5% (P<0.002). Overall SBP and DBP measurements were 12 and 4 mm Hg lower, respectively, when receiving bumetanide or furosemide vs placebo.  Both furosemide and bumetanide increased TC by 5.0% (P<0.002), HDL-

## IX. Cost

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of '\$' signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 10. Relative Cost of the Loop Diuretics**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost
Bumetanide	injection, tablet	N/A	N/A	\$\$
Ethacrynic acid	tablet	Edecrin®*	\$\$\$\$\$	\$\$\$\$\$
Furosemide	injection, solution, tablet	Lasix®*	\$\$\$	\$
Torsemide	tablet	N/A	N/A	\$

\*Generic is available in at least one dosage form or strength.

N/A=Not available

## X. Conclusions

All of the loop diuretics are approved for the treatment of edema associated with congestive heart failure, hepatic disease, or renal disease. Furosemide and torsemide are also approved for the treatment of hypertension. Additionally, ethacrynic acid is approved for the short-term treatment of ascites (due to malignancy, idiopathic edema, and lymphedema) and for the short-term treatment of hospitalized pediatric patients with congenital heart disease or the nephrotic syndrome.<sup>3-6</sup> All agents are available in a generic formulation.

Guidelines recommend the use of diuretics and sodium restriction for the management of ascites due to cirrhosis. Spironolactone is recommended as first-line therapy, either as monotherapy or in combination with furosemide.

Amiloride or eplerenone are alternative treatment options in patients experiencing gynecomastia with

**spironolactone**.<sup>20</sup> Several studies have compared furosemide and torsemide in cirrhotic patients with ascites. Although torsemide significantly increased natriuresis and diuresis compared to furosemide, these effects were not consistently demonstrated across the studies. There was no difference in plasma renin or aldosterone concentrations among the treatment groups.<sup>21-24</sup>

For the treatment of chronic heart failure, guidelines recommend the use of diuretics in all patients who have evidence of volume overload. Loop diuretics are generally recommended as initial therapy in patients with left ventricular dysfunction. For those with persistent fluid retention despite treatment with a loop diuretic, a thiazide diuretic or metolazone may be added to the regimen. In patients with normal left ventricular function, either a thiazide diuretic or loop diuretic may be used as initial therapy to manage fluid overload.<sup>9-10</sup> There are relatively few studies that have directly compared the loop diuretics for the treatment of chronic heart failure. In open-label trials, torsemide decreased mortality, hospitalizations and improved NYHA functional class compared to treatment with furosemide. However, due to limitations in the study designs, it is difficult to draw firm conclusions about the results of these studies.<sup>31-33</sup>

There are several published guidelines on the treatment of hypertension. Thiazide-type diuretics are frequently recommended as initial therapy in patients with uncomplicated hypertension.<sup>11-18</sup> According to the National Heart, Lung, and Blood Institute's Eighth Report of The Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 8), thiazide-type diuretics should be utilized first-line for most patients with hypertension, either alone or in combination with another hypertensive from a different medication class (e.g., ACE inhibitors, ARBs,  $\beta$ -blockers, calcium channel blockers).<sup>11</sup> Several guidelines consistently recommend that the selection of an antihypertensive agent be based on compelling indications for use.<sup>11-18</sup> Most patients will require more than one antihypertensive medication to achieve blood pressure goals.<sup>11-18</sup>

In clinical trials, the thiazide diuretics have been shown to effectively lower blood pressure.<sup>40-49</sup> Some studies suggest that hydrochlorothiazide is more effective than a loop diuretic for lowering blood pressure.<sup>8</sup> However, a loop diuretic should be used when the glomerular filtration rate is  $<30$  mL/min.<sup>1,2</sup>

Serious adverse events reported with the loop diuretics include electrolyte abnormalities, hypersensitivity reactions, and ototoxicity. Ethacrynic acid has a higher rate of ototoxicity than other loop diuretics and is less commonly used. Patients allergic to sulfonamides may also show hypersensitivity to bumetanide, furosemide, and torsemide. Ethacrynic acid is the only loop diuretic that is not a sulfonamide derivative and can be safely used in patients with a sulfonamide allergy.<sup>3-7</sup>

There is insufficient evidence to support that one brand loop diuretic is safer or more efficacious than another. Formulations without a generic alternative should be managed through the medical justification portion of the prior authorization process.

Therefore, all brand loop diuretics within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

## **XI. Recommendations**

No brand loop diuretic is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

**Alabama Medicaid Agency  
Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Potassium-Sparing Diuretics  
AHFS Class 402816  
May 4, 2022**

## 1. Overview

The potassium-sparing diuretics are approved for the treatment of congestive heart failure, edema, and hypertension.<sup>1-5</sup> They inhibit sodium-potassium ion exchange at the distal convoluted tubule, cortical collecting tubule, and collecting duct. This reduces both potassium and hydrogen secretion and their subsequent excretion.<sup>1-9</sup> When used alone, potassium-sparing diuretics have a weak diuretic and antihypertensive effect and increased risk of hyperkalemia.<sup>5</sup> The potassium-sparing diuretics are generally used in combination with other diuretics to help restore normal serum potassium levels or to prevent the development of hypokalemia.<sup>1-5</sup> Amiloride and triamterene are both available as a fixed-dose combination with hydrochlorothiazide. Hydrochlorothiazide inhibits the reabsorption of sodium and chloride in the cortical thick ascending limb of the loop of Henle and the early distal tubules. This action leads to an increase in the urinary excretion of sodium and chloride.<sup>5-8</sup>

The potassium-sparing diuretics that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. All of the products are available in a generic formulation. This class was last reviewed in February 2020.

**Table 1. Potassium-Sparing Diuretics Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
<b>Single Entity Agents</b>			
Amiloride	tablet	N/A	amiloride
Triamterene	capsule	N/A	triamterene
<b>Combination Products</b>			
Amiloride and hydrochlorothiazide	tablet	N/A	amiloride and hydrochlorothiazide
Triamterene and hydrochlorothiazide	capsule, tablet	Maxzide®*	triamterene and hydrochlorothiazide

\*Generic is available in at least one dosage form or strength.

PDL=Preferred Drug List

N/A=Not available

## II. Evidence-Based Medicine and Current Treatment Guidelines

Current treatment guidelines that incorporate the use of the potassium-sparing diuretics are summarized in Table 2.

**Table 2. Treatment Guidelines Using the Potassium-Sparing Diuretics**

Clinical Guideline	Recommendation(s)
American Heart Association/American College of Cardiology/Heart Failure Society of America: <b>2022 AHA/ACC/HFSA Guideline for the Management of Heart Failure (2022)</b> <sup>9</sup>	<b>Treatment of Stage A heart failure (HF)</b> <ul style="list-style-type: none"> <li>Hypertension should be controlled in accordance with guideline-directed medication therapy for hypertension to prevent symptomatic HF. (LoE: A)</li> <li>In patients with type 2 diabetes and either established CVD or at high cardiovascular risk, SGLT-2 inhibitors should be used to prevent hospitalizations for HF. (LoE: A)</li> <li>In the general population, healthy lifestyle habits such as regular physical activity, maintaining normal weight, healthy dietary patterns, and avoiding smoking are helpful to reduce future risk of HF. (LoE: B)</li> <li>Patients at risk of developing HF, natriuretic peptide biomarker-based screening followed by team-based care, including a cardiovascular specialist optimizing therapy, can be useful to prevent the development of LV dysfunction (systolic or diastolic) or new-onset HF. (LoE: B)</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><b>Treatment of Stage B heart failure</b></p> <ul style="list-style-type: none"> <li>• In patients with LVEF≤40%, ACE inhibitors should be used to prevent HF and reduce mortality. (LoE: A)</li> <li>• In patients with a recent or remote history of MI or ACS, statins should be used to prevent symptomatic HF and adverse cardiovascular events. (LoE: A)</li> <li>• In patients with a recent MI and LVEF≤40% who are intolerant to ACE inhibitors, ARB should be used to prevent symptomatic HF and reduce mortality. (LoE: B)</li> <li>• In patients with a recent or remote history of MI or ACS and LVEF≤40%, evidence-based beta blockers should be used to reduce mortality. (LoE: B)</li> <li>• In patients who are at least 40 days post-MI with LVEF ≤30% and NYHA class I symptoms while receiving guideline-directed medication therapy and have reasonable expectation of meaningful survival for greater than one year, an implantable cardioverter-defibrillator is recommended for primary prevention of sudden cardiac death to reduce total mortality. (LoE: B)</li> <li>• In patients with LVEF ≤40%, beta blockers should be used to prevent symptomatic HF. (LoE: C)</li> <li>• In patients with LVEF ≤50%, thiazolidinediones should not be used because they increase the risk of HF, including hospitalizations. (LoE: B)</li> <li>• In patients with LVEF ≤50%, nondihydropyridine calcium channel blockers with negative inotropic effects may be harmful. (LoE: C)</li> </ul> <p><b>Treatment for Stage C Heart Failure with Reduced Ejection Fraction (HFrEF)</b></p> <ul style="list-style-type: none"> <li>• For patients with stage C HF, avoiding excessive sodium intake is reasonable to reduce congestive symptoms. (LoE: C)</li> <li>• In patients with HF who have fluid retention, diuretics are recommended to relieve congestion, improve symptoms, and prevent worsening HF. (LoE: B)</li> <li>• For patients with HF and congestive symptoms, addition of a thiazide (e.g., metolazone) to treatment with a loop diuretic should be reserved for patients who do not respond to moderate or high dose loop diuretics to minimize electrolyte abnormalities. (LoE: B)</li> <li>• In patients with HFrEF and NYHA class II to III symptoms, the use of an ARNI is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, the use of an ACE inhibitor is beneficial to reduce morbidity and mortality when the use of an ARNI is not feasible. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, who are intolerant to an ACE inhibitor because of cough or angioedema, and when the use of an ARNI is not feasible, the use of an ARB is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with chronic symptomatic HFrEF NYHA class II or III who tolerate an ACE inhibitor or ARB, replacement by an ARNI is recommended to further reduce morbidity and mortality. (LoE: B)</li> <li>• ARNIs should not be administered concomitantly with ACE inhibitors or within 36 hours of the last dose of an ACE inhibitor. (LoE: B)</li> <li>• ARNI or ACE inhibitors should not be administered in patients with a history of angioedema. (LoE: C)</li> <li>• In patients with HFrEF, with current or previous symptoms, use of one of the three β-blockers proven to reduce mortality (e.g., bisoprolol, carvedilol, sustained-release metoprolol succinate) is recommended to reduce mortality and hospitalizations. (LoE: A)</li> <li>• In patients with HFrEF and NYHA class II to IV symptoms, a mineralocorticoid receptor antagonist (spironolactone or eplerenone) is recommended to reduce morbidity and mortality, if eGFR is &gt;30 mL/min/1.73 m<sup>2</sup> and serum potassium</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>is &lt;5.0 mEq/L. Careful monitoring of potassium, renal function, and diuretic dosing should be performed at initiation and closely followed thereafter to minimize risk of hyperkalemia and renal insufficiency. (LoE: A)</p> <ul style="list-style-type: none"> <li>• In patients taking a mineralocorticoid receptor antagonist whose serum potassium cannot be maintained at &lt;5.5 mEq/L, mineralocorticoid receptor antagonist should be discontinued to avoid life threatening hyperkalemia. (LoE: B)</li> <li>• In patients with symptomatic chronic HFrEF, SGLT-2 an inhibitor is recommended to reduce hospitalization for HF and cardiovascular mortality, irrespective of the presence of type 2 diabetes. (LoE: A)</li> <li>• The combination of hydralazine and isosorbide dinitrate is recommended to improve symptoms and reduce morbidity and mortality for patients self-identified as African Americans with NYHA class III to IV HFrEF receiving optimal therapy. (LoE: A)</li> <li>• In patients with current or previous symptomatic HFrEF who cannot be given first-line agents, such as an ARNI, ACE inhibitor or ARB because of drug intolerance or renal insufficiency, a combination of hydralazine and isosorbide dinitrate might be considered to reduce morbidity and mortality. (LoE: C)</li> <li>• In patients with HF class II to IV symptoms, omega-3 polyunsaturated fatty acid supplementation may be reasonable to use as adjunctive therapy to reduce mortality and cardiovascular hospitalizations. (LoE: B)</li> <li>• In patients with chronic HFrEF without specific indication (e.g., venous thromboembolism, atrial fibrillation, a previous thromboembolic event, or a cardioembolic source, anticoagulation is not recommended. (LoE: B)</li> <li>• Dihydropyridine and non-dihydropyridine calcium channel blockers are not recommended for patients with HFrEF. (LoE: A)</li> <li>• In patients with HFrEF, vitamins, nutritional supplements, and hormonal therapy are not recommended other than to correct specific deficiencies. (LoE: B)</li> <li>• In patients with HFrEF, class IC antiarrhythmic medication and dronedarone may increase risk of mortality. (LoE: A)</li> <li>• In patients with HFrEF, thiazolidinediones increase the risk of worsening HF symptoms and hospitalizations. (LoE: A)</li> <li>• In patients with type 2 diabetes and high cardiovascular risk, the DPP-4 inhibitors, saxagliptin and alogliptin, increase the risk of HF hospitalization and should be avoided in patients with HF. (LoE: B)</li> <li>• In patients with HFrEF, nonsteroidal anti-inflammatory drugs worsen HF symptoms and should be avoided or withdrawn whenever possible. (LoE: B)</li> <li>• For patients with symptomatic (NYHA class II to III) stable chronic HFrEF (LVEF ≤35%) who are receiving guideline-directed medical therapy, including a maximally tolerated dose of a beta blocker, and who are in sinus rhythm with a heart rate of ≥70 beats per minute at rest, ivabradine can be beneficial to reduce HF hospitalizations and cardiovascular death. (LoE: B)</li> <li>• In patients with symptomatic HFrEF despite guideline-directed medical therapy or who are unable to tolerate guideline-directed medical therapy, digoxin might be considered to decrease hospitalizations for HF. (LoE: B)</li> <li>• In select high-risk patients with HFrEF and recent worsening of HF already on guideline-directed medical therapy, an oral soluble guanylate cyclase stimulator (vericiguat) may be considered to reduce HF hospitalization and cardiovascular death. (LoE: B)</li> </ul> <p><u>Pharmacological treatment for Stage C HF with mildly reduced EF and improved EF</u></p> <ul style="list-style-type: none"> <li>• In patients with HF with mildly reduced EF, SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• Among patients with current or previous symptomatic HF with mildly reduced EF (LVEF, 41 to 49%), use of evidence-based beta blockers for HFrEF, ARNI, ACE inhibitor or ARB, and mineralocorticoid receptor antagonists may be considered to reduce the risk of HF hospitalization and cardiovascular mortality, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• In patients with HF with improved EF after treatment, guideline-directed medical therapy should be continued to prevent relapse of HF and LV dysfunction, even in patients who may become asymptomatic. (LoE: B)</li> </ul> <p><u>Pharmacological treatment for Stage C HF with preserved EF (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• Patients with hypertension and HFpEF should have medication titrated to attain blood pressure targets in accordance with published clinical practice guidelines to prevent morbidity. (LoE: C)</li> <li>• SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• In patients with HFpEF, the use of a mineralocorticoid receptor antagonist, ARB, or ARNI may be considered to decrease hospitalizations, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• Routine use of nitrates or phosphodiesterase-5 inhibitors to increase activity or quality of life in patients with HFpEF is ineffective. (LoE: B)</li> </ul> <p><u>Treatment of Stage D (advanced/refractory) HF</u></p> <ul style="list-style-type: none"> <li>• For patients with advanced HF and hyponatremia, the benefit of fluid restriction to reduce congestive symptoms is uncertain. (LoE: C)</li> <li>• Continuous intravenous inotropic support is reasonable as “bridge therapy” in patients with HF (Stage D) refractory to guideline-directed medical therapy and device therapy who are eligible for and awaiting mechanical circulatory support or cardiac transplantation. (LoE: B)</li> <li>• In select patients with HF Stage D, despite optimal guideline-directed medical therapy and device therapy who are ineligible for either mechanical circulatory support or cardiac transplantation, continuous intravenous inotropic support may be considered as palliative therapy for symptom control and improvement in functional status. (LoE: B)</li> <li>• Long-term use of either continuous or intermittent, intravenous inotropic agents, for reasons other than palliative care or as a bridge to advanced therapies, is potentially harmful. (LoE: B)</li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure (2021)</b><sup>10</sup></p>	<p><u>Pharmacological treatments indicated in patients with (NYHA Class II-IV) heart failure with reduced ejection fraction</u></p> <ul style="list-style-type: none"> <li>• An ACE inhibitor is recommended, in addition to a <math>\beta</math>-blocker, for symptomatic patients with HFrEF to reduce the risk of HF hospitalization and death.</li> <li>• A mineralocorticoid receptor antagonist (MRA) is recommended for patients with HFrEF, who remain symptomatic despite treatment with an ACE inhibitor and a <math>\beta</math>-blocker, to reduce the risk of HF hospitalization and death.</li> <li>• Dapagliflozin or empagliflozin are recommended for patients with HFrEF to reduce the risk of HF hospitalization and death. Dapagliflozin or empagliflozin are recommended, in addition to optimal medical therapy with an ACE-I/ARNI, a <math>\beta</math>-blocker and an MRA, for patients with HFrEF regardless of diabetes status.</li> <li>• Sacubitril-valsartan is recommended as a replacement for an ACE inhibitor to further reduce the risk of HF hospitalization and death in ambulatory patients with HFrEF who remain symptomatic despite optimal treatment with an ACE inhibitor, a <math>\beta</math>-blocker, and a mineralocorticoid receptor antagonist.</li> <li>• Diuretics are recommended in order to improve symptoms and exercise capacity in patients with signs and/or symptoms of congestion.</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization or</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm despite treatment with an evidence-based dose of <math>\beta</math>-blocker (or maximum tolerated dose below that), ACE inhibitor (or ARB), and a mineralocorticoid receptor antagonist (or ARB).</p> <ul style="list-style-type: none"> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm who are unable to tolerate or have contraindications for a <math>\beta</math>-blocker. Patients should also receive an ACE inhibitor (or ARB) and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• An ARB is recommended to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients unable to tolerate an ACE inhibitor (patients should also receive a <math>\beta</math>-blocker and mineralocorticoid receptor antagonist).</li> <li>• An ARB may be considered to reduce the risk of HF hospitalization and death in patients who are symptomatic despite treatment with a <math>\beta</math>-blocker who are unable to tolerate a mineralocorticoid receptor antagonist.</li> <li>• Vericiguat may be considered in patients in NYHA class II-IV who have had worsening HF despite treatment with an ACE-I (or ARNI), a <math>\beta</math>-blocker and an MRA to reduce the risk of CV mortality or HF hospitalization.</li> <li>• Hydralazine and isosorbide dinitrate should be considered in self-identified black patients with LVEF <math>\leq 35\%</math> or with an LVEF <math>&lt; 45\%</math> combined with a dilated LV in NYHA Class III-IV despite treatment with an ACE-I a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist to reduce the risk of HF hospitalization and death.</li> <li>• Hydralazine and isosorbide dinitrate may be considered in symptomatic patients with HFrEF who can tolerate neither an ACE inhibitor nor an ARB (or they are contraindicated) to reduce the risk of death.</li> <li>• Digoxin is a treatment with less-certain benefits and may be considered in symptomatic patients in sinus rhythm despite treatment with an ACE inhibitor (or ARB), a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist, to reduce the risk of hospitalization (both all-cause and HF-hospitalizations).</li> </ul> <p><u>Recommendations for treatment of patients with (NYHA class II-IV) heart failure with mildly reduced ejection fraction (HFmrEF)</u></p> <ul style="list-style-type: none"> <li>• Diuretics are recommended in patients with congestion and HFmrEF in order to alleviate symptoms and signs.</li> <li>• An ACE inhibitor may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An ARB may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• A <math>\beta</math>-blocker may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An MRA may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• Sacubitril/valsartan may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> </ul> <p><u>Recommendations for treatment of patients with heart failure with preserved ejection fraction (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• It is recommended to screen patients with HFpEF for both cardiovascular and noncardiovascular comorbidities, which, if present, should be treated provided safe and effective interventions exist to improve symptoms, well-being and/or prognosis.</li> <li>• Diuretics are recommended in congested patients with HFpEF in order to alleviate symptoms and signs.</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><u>Recommendations for the primary prevention of heart failure in patients with risk factors for its development</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension is recommended to prevent or delay the onset of HF and prolong life.</li> <li>• Treatment with statins is recommended in patients at high risk of CV disease or with CV disease in order to prevent or delay the onset of HF, and to prevent HF hospitalizations.</li> <li>• SGLT2 inhibitors (canagliflozin, dapagliflozin, empagliflozin, ertugliflozin, sotagliflozin) are recommended in patients with diabetes at high risk of CV disease or with CV disease in order to prevent HF hospitalizations.</li> <li>• Counselling against sedentary habit, obesity, cigarette smoking, and alcohol abuse is recommended to prevent or delay the onset of HF.</li> </ul> <p><u>Recommendations for the initial management of patients with acute heart failure – pharmacotherapy</u></p> <ul style="list-style-type: none"> <li>• Intravenous loop diuretics are recommended for all patients with acute HF admitted with signs/symptoms of fluid overload to improve symptoms. It is recommended to regularly monitor symptoms, urine output, renal function and electrolytes during use of intravenous diuretics.</li> <li>• Combination of a loop diuretic with thiazide type diuretic should be considered in patients with resistant oedema who do not respond to an increase in loop diuretic doses.</li> <li>• In patients with acute HF and SBP &gt;110 mmHg, intravenous vasodilators may be considered as initial therapy to improve symptoms and reduce congestion.</li> <li>• Inotropic agents may be considered in patients with SBP &lt;90 mmHg and evidence of hypoperfusion who do not respond to standard treatment, including fluid challenge, to improve peripheral perfusion and maintain end-organ function.</li> <li>• Inotropic agents are not recommended routinely, due to safety concerns, unless the patient has symptomatic hypotension and evidence of hypoperfusion.</li> <li>• A vasopressor, preferably norepinephrine, may be considered in patients with cardiogenic shock to increase blood pressure and vital organ perfusion.</li> <li>• Thromboembolism prophylaxis (e.g. with LMWH) is recommended in patients not already anticoagulated and with no contraindication to anticoagulation, to reduce the risk of deep venous thrombosis and pulmonary embolism.</li> <li>• Routine use of opiates is not recommended, unless in selected patients with severe/intractable pain or anxiety.</li> </ul>
<p>Eighth Joint National Committee (JNC 8): <b>2014 Evidence-based Guideline for the Management of High Blood Pressure in Adults</b> (2014)<sup>11</sup></p>	<ul style="list-style-type: none"> <li>• Pharmacologic treatment should be initiated in patients ≥60 years of age to lower blood pressure at systolic blood pressure ≥150 mm Hg or diastolic blood pressure ≥90 mm Hg and to a goal systolic blood pressure &lt;150 mm Hg and goal diastolic blood pressure &lt;90 mm Hg. Adjustment of treatment is not necessary if treatment results in lower blood pressure and treatment is well tolerated and without adverse effects on health or quality of life.</li> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at diastolic blood pressure ≥90 mm Hg to a goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥150 mm Hg to a goal diastolic blood pressure &lt;140 mm Hg.</li> <li>• For patients ≥18 years of age with chronic kidney disease or diabetes, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥140 mm Hg or diastolic blood pressure ≥90 mm Hg and to a goal systolic blood pressure &lt;140 mm Hg and goal diastolic blood pressure &lt;90 mm Hg.</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• Initial antihypertensive treatment for the general nonblack population, including those with diabetes, should include thiazide-type diuretic, calcium channel blocker (CCB), ACE inhibitor, or ARB.</li> <li>• Initial antihypertensive treatment for the general black population, including those with diabetes, should include thiazide-type diuretic or CCB.</li> <li>• For patients <math>\geq 18</math> years of age with chronic kidney disease regardless of race or diabetes status, initial (or add-on) treatment should include an ACE inhibitor or ARB to improve kidney outcomes.</li> <li>• The main goal of antihypertensive treatment is to attain and maintain goal blood pressure.</li> <li>• If goal blood pressure is not attained within a month of treatment, the dose of the initial drug should be increased or second drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• If goal is not achieved with two drugs, a third drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• An ACE inhibitor and ARB should not be used together.</li> <li>• Antihypertensive classes can be used if the patient is unable to achieve goal blood pressure with three agents or had a contraindication to a preferred class.</li> <li>• If blood pressure is not able to be achieved or in complicated patients, referral to a hypertension specialist may be indicated.</li> </ul>
<p>International Society of Hypertension: <b>Global Hypertension Practice Guidelines (2020)</b><sup>12</sup></p>	<p><b>Lifestyle modifications</b></p> <ul style="list-style-type: none"> <li>• Lifestyle modification is the first line of antihypertensive treatment.</li> <li>• Salt reduction: Reduce salt added when preparing foods, and at the table. Avoid or limit consumption of high salt foods such as soy sauce, fast foods and processed food including breads and cereals high in salt.</li> <li>• Healthy diet: Eating a diet that is rich in whole grains, fruits, vegetables, polyunsaturated fats and dairy products and reducing food high in sugar, saturated fat and trans fats, such as the DASH diet.</li> <li>• Healthy drinks: Moderate consumption of coffee, green and black tea. Other beverages that can be beneficial include karkadé (hibiscus) tea, pomegranate juice, beetroot juice and cocoa.</li> <li>• Moderation of alcohol consumption: The recommended daily limit for alcohol consumptions is 2 standard drinks for men and 1.5 for women (10 g alcohol/standard drink). Avoid binge drinking.</li> <li>• Weight reduction: Body weight control is indicated to avoid obesity. Particularly abdominal obesity should be managed. Ethnic-specific cut-offs for BMI and waist circumference should be used. Alternatively, a waist-to-height ratio <math>&lt; 0.5</math> is recommended for all populations.</li> <li>• Smoking cessation: Smoking is a major risk factor for cardiovascular disease (CVD), COPD and cancer. Smoking cessation and referral to smoking cessation programs are advised.</li> <li>• Regular physical activity: Studies suggest that regular aerobic and resistance exercise may be beneficial for both the prevention and treatment of hypertension. Moderate intensity aerobic exercise (walking, jogging, cycling, yoga, or swimming) for 30 minutes on five to seven days per week. Strength training also can help reduce blood pressure. Performance of resistance/strength exercises on two to three days per week.</li> <li>• Reduce stress and induce mindfulness: Stress should be reduced and mindfulness or meditation introduced into the daily routine.</li> <li>• Reduce exposure to air pollution and cold temperature: Evidence from studies support a negative effect of air pollution on blood pressure in the long-term.</li> </ul> <p><b>Pharmacological Treatment</b></p> <ul style="list-style-type: none"> <li>• Ideal characteristics of drug treatment <ul style="list-style-type: none"> <li>○ Treatments should be evidence-based in relation to morbidity/mortality</li> </ul> </li> </ul>

Clinical Guideline	Recommendation(s)
	<p>prevention.</p> <ul style="list-style-type: none"> <li>○ Use a once-daily regimen which provides 24-hour blood pressure control.</li> <li>○ Treatment should be affordable and/or cost-effective relative to other agents.</li> <li>○ Treatments should be well-tolerated.</li> <li>○ Evidence of benefits of use of the medication in populations to which it is to be applied.</li> </ul> <ul style="list-style-type: none"> <li>● General scheme for drug treatment           <ul style="list-style-type: none"> <li>○ Lifestyle modification is the first line of antihypertensive treatment.</li> <li>○ Grade 1 hypertension (BP 140 to 159/ 90 to 99): Immediate drug treatment in high-risk patients or those with CVD, chronic kidney disease (CKD), diabetes mellitus (DM), or hypertension-mediated organ damage (HMOD). Drug treatment after three to six months of lifestyle intervention if BP still not controlled in low to moderate risk patients.</li> <li>○ Grade 2 hypertension (BP <math>\geq</math>160/100): Immediate drug treatment in all patients.</li> </ul> </li> <li>● Core drug-treatment strategy           <ul style="list-style-type: none"> <li>○ Step 1: Dual low-dose combination (ACE inhibitor or ARB plus dihydropyridine-calcium channel blockers (DHP-CCB)); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance; consider ACE/ARB plus DHP-CCB or DHP-CCB plus thiazide-like diuretics in black patients.</li> <li>○ Step 2: Dual full-dose combination (ACE inhibitor or ARB plus DHP-CCB); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance.</li> <li>○ Step 3: Triple combination (ACE/ARB plus DHP-CCB plus thiazide-like diuretic).</li> <li>○ Step 4, resistant hypertension: triple combination plus spironolactone or other drug, alternatives include amiloride, doxazosin, eplerenone, clonidine, or <math>\beta</math>-blocker. Caution with spironolactone or other potassium sparing diuretics when estimated GFR <math>&lt;</math>45 mL/min/1.73m<sup>2</sup> or K<sup>+</sup> <math>&gt;</math>4.5 mmol/L.</li> <li>○ Consider <math>\beta</math>-blockers at any treatment step when there is a specific indications for their use, e.g., heart failure, angina, post-MI, atrial fibrillation, or younger women planning pregnancy or pregnant.</li> </ul> </li> </ul>
<p>Hypertension Canada: 2020 Guidelines for the Prevention, Diagnosis, Risk Assessment, and Treatment of Hypertension in Adults and Children (2020)<sup>13</sup></p>	<p><u>Indications for drug therapy for adults with hypertension without compelling indications for specific agents</u></p> <ul style="list-style-type: none"> <li>● Antihypertensive therapy should be prescribed for average diastolic blood pressure (DBP) measurements of <math>\geq</math>100 mmHg or average systolic blood pressure (SBP) measurements of <math>\geq</math>160 mmHg in patients without macrovascular target organ damage or other cardiovascular risk factors.</li> <li>● Antihypertensive therapy should be strongly considered for average DPB readings <math>\geq</math>90 mmHg or for average SBP readings <math>\geq</math>140 mmHg in the presence of macrovascular target organ damage or other independent cardiovascular risk factors.</li> <li>● For high-risk patients, aged 50 years or older, with SBP levels <math>\geq</math>130 mmHg, intensive management to target a SBP <math>&lt;</math>120 mmHg should be considered. Patient selection for intensive management is recommended and caution should be taken in certain high-risk groups.</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><u>Indications for drug therapy for adults with diastolic and with or without systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be with either monotherapy or single pill combination (SPC). <ul style="list-style-type: none"> <li>○ Recommended monotherapy choices are: <ul style="list-style-type: none"> <li>▪ A thiazide/thiazide-like diuretic, with longer-acting diuretics preferred;</li> <li>▪ A <math>\beta</math>-blocker (in patients &lt;60 years of age);</li> <li>▪ An angiotensin-converting enzyme (ACE) inhibitor (in nonblack patients);</li> <li>▪ An angiotensin receptor blocker (ARB); or</li> <li>▪ A long-acting calcium channel blocker (CCB).</li> </ul> </li> <li>○ Recommended SPC choices are those in which an ACE inhibitor is combined with a CCB, ARB with a CCB, or ACE inhibitor or ARB with a diuretic.</li> <li>○ Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> </ul> </li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line choices. Useful choices include a thiazide/thiazide-like diuretic or CCB with either: ACE inhibitor, ARB, or <math>\beta</math>-blocker. Caution should be exercised in combining a nondihydropyridine CCB and a <math>\beta</math>-blocker. The combination of an ACE inhibitor and an ARB is not recommended.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other antihypertensive drugs may be added.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated hypertension; <math>\beta</math>-blockers are not recommended as first-line therapy for uncomplicated hypertension in patients <math>\geq 60</math> years of age; and ACE inhibitors are not recommended as first-line therapy for uncomplicated hypertension in black patients. However, these agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Indications for drug therapy for adults with isolated systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be single-agent therapy with a thiazide/thiazide-like diuretic, a long-acting dihydropyridine CCB, or an ARB. If there are adverse effects, another drug from this group should be substituted. Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line options.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other classes of drugs (such as <math>\alpha</math>-blockers, ACE inhibitors, centrally acting agents, or nondihydropyridine CCBs) may be combined or substituted.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated isolated systolic hypertension; and <math>\beta</math>-blockers are not recommended as first-line therapy for isolated systolic hypertension in patients <math>\geq 60</math> years of age. However, both agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Guidelines for hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• For most hypertensive patients with CAD, an ACE inhibitor or ARB is recommended.</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• For hypertensive patients with CAD, but without coexisting systolic heart failure, the combination of an ACE inhibitor and ARB is not recommended.</li> <li>• For high-risk hypertensive patients, when combination therapy is being used, choices should be individualized. The combination of an ACE inhibitor and a dihydropyridine CCB is preferable to an ACE inhibitor and a thiazide/thiazide-like diuretic in selected patients.</li> <li>• For patients with stable angina pectoris but without previous heart failure, myocardial infarction, or coronary artery bypass surgery, either a <math>\beta</math>-blocker or CCB can be used as initial therapy.</li> <li>• Short-acting nifedipine should not be used.</li> <li>• When decreasing SBP to target levels in patients with established CAD (especially if isolated systolic hypertension is present), be cautious when the DBP is <math>\leq 60</math> mmHg because of concerns that myocardial ischemia might be exacerbated, especially in patients with left ventricular hypertrophy (LVH).</li> </ul> <p><u>Guidelines for patients with hypertension who have had a recent myocardial infarction</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should include a <math>\beta</math>-blocker as well as an ACE inhibitor.</li> <li>• An ARB can be used if the patient is intolerant of an ACE inhibitor.</li> <li>• CCBs may be used in patients after myocardial infarction when <math>\beta</math>-blockers are contraindicated or not effective. Nondihydropyridine CCBs should not be used when there is heart failure, evidenced by pulmonary congestion on examination or radiography.</li> </ul> <p><u>Treatment of hypertension in association with heart failure</u></p> <ul style="list-style-type: none"> <li>• In patients with systolic dysfunction (ejection fraction <math>&lt;40\%</math>), ACE inhibitors and <math>\beta</math>-blockers are recommended for initial therapy. Aldosterone antagonists (mineralocorticoid receptor antagonists) may be combined in treatment for patients with a recent cardiovascular hospitalization, acute myocardial infarction, elevated B-type natriuretic peptide or N-terminal pro-B-type natriuretic peptide level, or New York Heart Association (NYHA) Class II-IV symptoms. Careful monitoring for hyperkalemia is recommended when combining an aldosterone antagonist with ACE inhibitor or ARB treatment. Other diuretics are recommended as additional therapy if needed. Beyond considerations of BP control, doses of ACE inhibitors or ARBs should be titrated to those reported to be effective in trials unless adverse effects become manifest.</li> <li>• An ARB is recommended if ACE inhibitors are not tolerated.</li> <li>• A combination of hydralazine and isosorbide dinitrate is recommended if ACE inhibitors and ARBs are contraindicated or not tolerated.</li> <li>• For hypertensive patients whose BP is not controlled, an ARB may be combined with an ACE inhibitor and other antihypertensive drug treatment. Careful monitoring should be used if combining an ACE inhibitor and an ARB because of potential adverse effects such as hypotension, hyperkalemia, and worsening renal function. Additional therapies may also include dihydropyridine CCBs.</li> <li>• An angiotensin receptor-neprilysin inhibitor (ARNI) should be used in place of an ACE inhibitor or ARB for patients with HFrEF (<math>&lt;40\%</math>) who remain symptomatic despite treatment with appropriate dose of guideline directed HF therapy. Eligible patients must have a serum potassium <math>&lt;5.2</math> mmol/L, an eGFR <math>\leq 30</math> mL/min/1.73m<sup>2</sup> and close surveillance of serum potassium and creatinine.</li> </ul> <p><u>Treatment of hypertension in association with stroke</u></p> <ul style="list-style-type: none"> <li>• BP management in acute ischemic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> <li>• BP management after acute ischemic stroke</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>○ Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack.</li> <li>○ After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently &lt;140/90 mmHg.</li> <li>○ Treatment with an ACE inhibitor and thiazide/thiazide-like diuretic combination is preferred.</li> <li>○ For patients with stroke, the combination of an ACE inhibitor and ARB is not recommended.</li> </ul> <ul style="list-style-type: none"> <li>● BP management in hemorrhagic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> </ul> <p><u>Treatment of hypertension in association with LVH</u></p> <ul style="list-style-type: none"> <li>● Hypertensive patients with LVH should be treated with antihypertensive therapy to decrease the rate of subsequent cardiovascular events.</li> <li>● The choice of initial therapy can be influenced by the presence of LVH. Initial therapy can be drug treatment using ACE inhibitors, ARBs, long-acting CCBs, or thiazide/thiazide-like diuretics. Direct arterial vasodilators such as hydralazine or minoxidil should not be used.</li> </ul> <p><u>Treatment of hypertension in association with nondiabetic chronic kidney disease</u></p> <ul style="list-style-type: none"> <li>● Individualize BP targets in patients with chronic kidney disease. Consider intensive targets (SBP &lt;120 mmHg) in appropriate patients.</li> <li>● For patients with hypertension and proteinuric chronic kidney disease (urinary protein &gt;150 mg per 24 hours or albumin to creatinine ratio &gt;30 mg/mmol), initial therapy should be an ACE inhibitor or an ARB if there is intolerance to ACE inhibitors.</li> <li>● In most cases, combination therapy with other antihypertensive agents might be needed to reach target BP levels.</li> <li>● The combination of an ACE inhibitor and ARB is not recommended for patients with nonproteinuric chronic kidney disease.</li> </ul> <p><u>Treatment of hypertension in association with renovascular disease</u></p> <ul style="list-style-type: none"> <li>● Patients with hypertension attributable to atherosclerotic renal artery stenosis should be primarily medically managed because renal angioplasty and stenting offers no benefit over optimal medical therapy alone.</li> <li>● Renal artery angioplasty and stenting for atherosclerotic hemodynamically significant renal artery stenosis could be considered for patients with uncontrolled hypertension resistant to maximally tolerated pharmacotherapy, progressive renal function loss, and acute pulmonary edema.</li> <li>● Patients with confirmed renal fibromuscular dysplasia (FMD) should be referred to a hypertension specialist.</li> <li>● Renal artery angioplasty without stenting is recommended for treatment of FMD-related renal artery stenosis. Stenting is not recommended unless needed because of a periprocedural dissection. Surgical revascularization should be considered in cases of complex lesions less amendable to angioplasty, stenosis associated with complex aneurysm, and restenosis despite two unsuccessful attempts of angioplasty.</li> </ul> <p><u>Treatment of hypertension in association with diabetes mellitus</u></p> <ul style="list-style-type: none"> <li>● Persons with diabetes mellitus should be treated to attain SBP of &lt;130 mmHg and DBP of &lt;80 mmHg.</li> <li>● For persons with cardiovascular or kidney disease, including microalbuminuria, or with cardiovascular risk factors in addition to diabetes and hypertension, an ACE inhibitor or an ARB is recommended as initial therapy.</li> <li>● For persons with diabetes and hypertension not included in other guidelines in</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>this section, appropriate choices include (in alphabetical order): ACE inhibitors, ARBs, dihydropyridine CCBs, and thiazide/thiazide-like diuretics.</p> <ul style="list-style-type: none"> <li>• If target BP levels are not achieved with standard-dose monotherapy, additional antihypertensive therapy should be used. For persons in whom combination therapy with an ACE inhibitor is being considered, a dihydropyridine CCB is preferable to a thiazide/thiazide-like diuretic.</li> </ul> <p><u>Resistant hypertension</u></p> <ul style="list-style-type: none"> <li>• Resistant hypertension is defined as BP above target despite three or more BP-lowering drugs at optimal doses preferably including a diuretic (and usually a renin-angiotensin-aldosterone system blocker and a CCB).</li> <li>• Accurate office and out-of-office BP measurement is essential.</li> <li>• Other reasons for apparent resistant hypertension should be eliminated before diagnosing true resistant hypertension, including nonadherence, white coat effect, and secondary hypertension.</li> <li>• Pharmacotherapy with the additional use of spironolactone, bisoprolol, doxazosin, amiloride, eplerenone, or clonidine with the baseline regimen decreases BP significantly, with the greatest BP-lowering shown with spironolactone.</li> <li>• Patients with resistant hypertension should be referred to providers with expertise in diagnosis and management of hypertension.</li> </ul> <p><u>Hypertension and pediatrics</u></p> <ul style="list-style-type: none"> <li>• BP should be measured regularly in children three years of age or older; the auscultatory method is the gold-standard at present.</li> <li>• Initial therapy should be monotherapy, with an ACE inhibitor or ARB (not first-line in black children), or a long-acting dihydropyridine CCB.</li> <li>• The treatment goal is systolic and diastolic office BP and/or ABPM &lt; 95<sup>th</sup> percentile or &lt;90<sup>th</sup> percentile in children with risk factors or target organ damage.</li> <li>• Complex cases should be referred to an expert in pediatric hypertension.</li> </ul> <p><u>Hypertension and pregnancy</u></p> <ul style="list-style-type: none"> <li>• Up to 7% of pregnancies are complicated by a hypertensive disorder of pregnancy, and approximately 5% of women will have chronic hypertension when they become pregnant.</li> <li>• The prevalence of hypertension in pregnancy is expected to increase with women becoming pregnant later in their reproductive years and the increasing prevalence of cardiovascular comorbidities such as increased preconception body mass index and maternal diabetes.</li> <li>• The possibility of pregnancy should be considered when managing women with hypertension who are of reproductive age.</li> <li>• Preconception counselling should be offered to all women with hypertension who are considering pregnancy.</li> <li>• ACE inhibitor and ARB therapy should be avoided before conception and during pregnancy unless there is a compelling indication for their use (i.e., proteinuric kidney disease).</li> <li>• Hypertension during pregnancy can increase the risk of adverse maternal and fetal outcomes, including an increased risk of preeclampsia, placental abruption, prematurity, small for gestational age infants, stillbirth, and maternal renal and retinal injury, thus generally requires involvement of an interdisciplinary team including obstetrical care providers.</li> <li>• Antihypertensive therapy is recommended for average SBP measurements of <math>\geq 140</math> mmHg or DBP measurements of <math>\geq 90</math> mmHg in pregnant women with chronic hypertension, gestational hypertension, or preeclampsia. Initial</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>antihypertensive therapy should be monotherapy from the following first-line drugs: oral labetalol, oral methyldopa, long-acting oral nifedipine, or other oral b-blockers (acebutolol, metoprolol, pindolol, and propranolol). Other antihypertensive drugs can be considered as second-line drugs including: clonidine, hydralazine, and thiazide diuretics.</p> <ul style="list-style-type: none"> <li>• Women with severe hypertension with SBP <math>\geq</math>160 mmHg or DBP <math>\geq</math>110 mmHg in pregnancy or postpartum require urgent antihypertensive therapy because it is considered an obstetrical emergency.</li> <li>• Antihypertensive drugs used in breastfeeding women include: labetalol, methyldopa, long-acting nifedipine, enalapril, or captopril.</li> </ul>
<p>European Society of Hypertension/ European Society of Cardiology: <b>2018 Guidelines for the management of arterial hypertension (2018)</b><sup>14</sup></p>	<p><u>Treatment strategies and choice of antihypertensive drugs</u></p> <ul style="list-style-type: none"> <li>• Diuretics (including thiazides, chlorthalidone, and indapamide), <math>\beta</math>-blockers, calcium channel blocker (CCB), angiotensin-converting enzyme (ACE) inhibitors, and angiotensin receptor blockers (ARBs) are all suitable for the initiation and maintenance of antihypertensive treatment, either as monotherapy or in some combinations.</li> <li>• Some agents should be considered as the preferential choice in specific conditions because used in trials in those conditions or because of greater effectiveness in specific types of organ damage. Preferred combinations should comprise a renin-angiotensin system (RAS) blocker (either an ACE inhibitor or an ARB) with a CCB or diuretic.</li> <li>• It is recommended that beta-blockers are combined with any of the other major drug classes when there are specific clinical situations, e.g. angina, post-myocardial infarction, heart failure, or heart rate control.</li> <li>• Initiation of antihypertensive therapy with a two-drug combination may be considered in patients with markedly high baseline blood pressure (BP) or at high cardiovascular (CV) risk.</li> <li>• The combination of two antagonists of the RAS is not recommended and should be discouraged.</li> <li>• Other drug combinations should be considered and probably are beneficial in proportion to the extent of BP reduction. However, combinations that have been successfully used in trials may be preferable.</li> <li>• Combinations of two antihypertensive drugs at fixed doses in a single tablet may be recommended and favored, because reducing the number of daily pills improves adherence, which is low in patients with hypertension. Exceptions are frail older patients and those at low risk and with grade one hypertension (particularly if systolic BP is <math>&lt;</math>150 mmHg).</li> <li>• It is recommended that if BP is not controlled with a three-drug combination, treatment should be increased by the addition of spironolactone or, if not tolerated, other diuretics such as amiloride or higher doses of other diuretics, a beta-blocker, or an alpha-blocker.</li> </ul> <p><u>Treatment strategies in white-coat and masked hypertension</u></p> <ul style="list-style-type: none"> <li>• In white-coat hypertensives without additional risk factors, therapeutic intervention may be limited to lifestyle changes only, but this decision should be accompanied by close follow-up.</li> <li>• In white-coat hypertensives with a higher CV risk or hypertension-mediated organ damage, drug treatment may be considered in addition to lifestyle changes.</li> <li>• In masked hypertension, both lifestyle measures and antihypertensive drug treatment should be considered, because this type of hypertension has been consistently found to have a CV risk very close to that of in- and out-of-office hypertension.</li> <li>• Antihypertensive drug up-titration should be considered in treated patients whose out-of-office BP is not controlled (i.e., masked uncontrolled</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>hypertension), because of the high CV risk of these patients.</p> <p><u>Antihypertensive treatment strategies in the elderly</u></p> <ul style="list-style-type: none"> <li>• It is recommended that older patients (<math>\geq 65</math> years) are treated with the same recommendations in non-older patient population. In very old patients (<math>\geq 80</math> years), it may be appropriate to initiate treatment with monotherapy.</li> <li>• In all older patients, when combination therapy is used, it is recommended that this is initiated at the lowest available doses. In all older patients, and especially very old or frail patients, the possible occurrence of postural BP should be closely monitored and symptoms of possible hypotensive episodes checked by ambulatory blood pressure monitoring.</li> <li>• Unless required for concomitant diseases, loop diuretics and alpha-blockers should be avoided because of their association with injurious falls.</li> <li>• Renal function should be frequently assessed to detect possible increases in serum creatinine and reductions in estimated glomerular filtration rate (eGFR) as a result of BP-related reductions in renal perfusion.</li> <li>• When treated, BP should be lowered to a systolic value of 130 to 139 mmHg and a diastolic value of <math>&lt; 80</math> mmHg if tolerated. Treated values of <math>&lt; 130</math> mmHg should be avoided.</li> </ul> <p><u>Treatment strategies in hypertensive women</u></p> <ul style="list-style-type: none"> <li>• Hormone therapy and selective estrogen receptor modulators are not recommended and should not be used for primary or secondary prevention of CVD.</li> <li>• In women with gestational hypertension, pre-existing hypertension superimposed by gestational hypertension, or with hypertension and subclinical organ damage or symptoms, initiation of drug treatments is recommended when SBP is <math>\geq 140</math> mmHg or DBP <math>\geq 90</math> mmHg. In all other cases, initiation of drug treatment is recommended when SBP is <math>\geq 150</math> mmHg or DBP is <math>\geq 95</math> mmHg.</li> <li>• Methyldopa, labetalol, and CCBs are recommended as the drugs of choice for the treatment of hypertension in pregnancy.</li> <li>• ACE inhibitors, ARBs, or direct renin inhibitors are not recommended during pregnancy.</li> <li>• SBP <math>\geq 170</math> mmHg or DBP <math>\geq 110</math> mmHg in a pregnant woman is an emergency, and admission to hospital is recommended.</li> <li>• In severe hypertension, drug treatment with intravenous (IV) labetalol, oral methyldopa, or nifedipine is recommended.</li> <li>• The recommended treatment for hypertensive crisis is IV labetalol or nicardipine and magnesium.</li> <li>• In pre-eclampsia associated with pulmonary edema, nitroglycerin given as an IV infusion is recommended.</li> <li>• In women with gestational hypertension or mild-pre-eclampsia, delivery is recommended at 37 weeks.</li> <li>• It is recommended to expedite delivery in pre-eclampsia with adverse conditions, such as visual disturbances or hemostatic disorders</li> <li>• In women at high risk of pre-eclampsia, provided they are at low risk of gastrointestinal hemorrhage, treatment with low dose aspirin from 12 weeks until delivery may be considered.</li> <li>• Methyldopa, labetalol, and nifedipine should be considered preferential antihypertensive drugs in pregnancy. Intravenous labetalol or infusion of nitroprusside should be considered in case of emergency (pre-eclampsia).</li> </ul> <p><u>Treatment strategies in patients with diabetes</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive drug treatment is recommended for people with diabetes when office BP is <math>\geq 140/90</math> mmHg.</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• A SBP goal &lt;130 mmHg is recommended in patients with diabetes and &lt;130 mmHg if tolerated, but not &lt;120 mmHg.</li> <li>• In older people, the target SBP range is 130 to 139 mmHg.</li> <li>• The DBP target in patients with diabetes is recommended to be &lt;80 mmHg, but not &lt;70 mmHg.</li> <li>• It is recommended to initiate treatment with a combination of a RAS blocker with a CCB or thiazide/thiazide-like diuretic.</li> <li>• It is recommended that individual drug choice takes comorbidities into account.</li> <li>• Simultaneous administration of two blockers of the RAS is not recommended and should be avoided in patients with diabetes.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with nephropathy</u></p> <ul style="list-style-type: none"> <li>• In patients with diabetic and non-diabetic CKD, it is recommended that an office BP of <math>\geq 140/90</math> mmHg be treated with lifestyle advice and BP-lowering medication.</li> <li>• In patients with diabetic or non-diabetic CKD, it is recommended to lower SBP to a range of 130 to 139 mmHg. And individualized treatments should be considered according to its tolerability and impact on renal function and electrolytes.</li> <li>• A combination of a RAS blocker with a CCB or a diuretic is recommended as initial therapy.</li> <li>• RAS blockers are more effective in reducing albuminuria than other antihypertensive agents, and are indicated in hypertensive patients in the presence of microalbuminuria or overt proteinuria.</li> <li>• Combination of two RAS blockers, though potentially more effective in reducing proteinuria, is not recommended.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with cerebrovascular disease</u></p> <ul style="list-style-type: none"> <li>• In patients with acute intracerebral hemorrhage, immediate BP lowering is not recommended for patients with SBP &lt;220 mmHg. In patients with SBP <math>\geq 220</math> mmHg, care acute BP lowering with IV therapy to &lt;180 mmHg should be considered.</li> <li>• In acute ischemic stroke, routine BP lowering with antihypertensive therapy is not recommended with the exceptions with the exceptions: in patients with acute ischemic stroke who are eligible for IV thrombolysis, BP should be carefully lowered and maintained at &lt;180/105 mmHg for at least the first 24 hours after thrombolysis; In patients with markedly elevated BP who do not receive fibrinolysis, drug therapy may be considered, based on clinical judgement, to reduce BP by 15% during the first 24 hours after the stroke onset.</li> <li>• In hypertensive patients with an acute cerebrovascular event, antihypertensive treatment is recommended immediately for transient ischemic attack (TIA) and after several days in ischemic stroke.</li> <li>• In all hypertensive patients with ischemic stroke or TIA, an SBP target range of 120 to 130 mmHg should be considered.</li> <li>• The recommended antihypertensive drug treatment strategy for stroke prevention is a RAS blocker plus a CCB or a thiazide-like diuretic.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with heart failure (HF) or left ventricular hypertrophy (LVH)</u></p> <ul style="list-style-type: none"> <li>• In hypertensive patients with heart failure (with reduced or preserved ejection fraction), BP-lowering treatment should be considered if <math>\geq 140/90</math> mmHg.</li> <li>• In patients with HFrEF, it is recommended that BP-lowering treatment comprises an ACE inhibitor or ARB, and a beta-blocker and a diuretic and/or mineralocorticoid receptor antagonist (MRA) if required.</li> <li>• Dihydropyridine CCBs may be added if BP control is not achieved.</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• In patients with HFpEF, BP treatment threshold and target values should be the same as for HFrEF).</li> <li>• Because no specific drug has proven its superiority, all major agents can be used.</li> <li>• In all patients with LVH, it is recommended to treat with a RAS blocker or in combination with a CCB or diuretic and SBP should be lowered to a range of 120 to 130 mmHg.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• In patients with CAD receiving BP-lowering drugs, it is recommended to target SBP to <math>\leq 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg. In older patients, the target is an SBP range of 130 to 140 mmHg. The target DBP is <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• In hypertensive patients with a history of myocardial infarction, beta-blockers and RAS blockers are recommended as part of treatment.</li> <li>• In patients with asymptomatic angina, beta-blockers and/or CCBs are recommended.</li> </ul>
<p>National Institute for Health and Clinical Excellence: <b>Hypertension in adults: diagnosis and management (2019)</b><sup>15</sup></p>	<p><u>Choosing antihypertensive drug treatment (for people with or without type II diabetes)</u></p> <ul style="list-style-type: none"> <li>• Where possible, recommend treatment with drugs taken only once a day.</li> <li>• Prescribe non-proprietary drugs where these are appropriate and minimize cost.</li> <li>• Offer people with isolated systolic hypertension (systolic blood pressure <math>\geq 160</math> mmHg) the same treatment as people with both raised systolic and diastolic blood pressure.</li> <li>• Offer antihypertensive drug treatment to women of child-bearing potential with diagnosed hypertension in line with recommendations in this guideline. For women considering pregnancy or who are pregnant or breastfeeding, manage hypertension in line with the recommendations on Management of pregnancy with chronic hypertension and Breastfeeding in 'Hypertension in pregnancy'.</li> <li>• When choosing antihypertensive drug treatment for adults of black African or African-Caribbean family origin, consider an angiotensin II receptor blocker, in preference to an angiotensin-converting enzyme inhibitor.</li> </ul> <p><u>Step one treatment</u></p> <ul style="list-style-type: none"> <li>• Patients <math>&lt; 55</math> years of age should be offered a step one antihypertensive with an angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB).</li> <li>• Offer an ACE inhibitor or an ARB to adults starting step 1 antihypertensive treatment who have type II diabetes and are of any age or family origin or those aged <math>&lt; 55</math> years but not of black African or African-Caribbean family origin.</li> <li>• If an ACE inhibitor is not tolerated, offer an ARB.</li> <li>• Do not combine an ACE inhibitor with an ARB for the treatment of hypertension.</li> <li>• Offer a calcium channel blocker (CCB) to adults starting step 1 antihypertensive treatment who are <math>&gt; 55</math> years of age and do not have diabetes and are of black African or African-Caribbean family origin and do not have type II diabetes and of any age.</li> <li>• If a CCB is not suitable, for example because of edema or intolerance, or if there is evidence of heart failure or a high risk of heart failure, offer a thiazide-like diuretic.</li> <li>• If diuretic treatment is to be initiated or changed, offer a thiazide-like diuretic, such as indapamide in preference to a conventional thiazide diuretic such as bendroflumethiazide or hydrochlorothiazide.</li> <li>• For adults with hypertension who are already receiving treatment with bendroflumethiazide or hydrochlorothiazide, who have stable, well-controlled</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>blood pressure, continue with their treatment.</p> <p><u>Step two treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering next step treatment for hypertension discuss with the person if they are taking their medicine as prescribed and support adherence in line with NICE's guideline on “Medicines adherence: involving patients decisions about prescribed medicines and supporting adherence”.</li> <li>• If hypertension is not controlled with a step one treatment of an ACE inhibitor or ARB, offer choice of one of the following drugs in addition to the step one treatment: a CCB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults taking step one treatment of a CCB, offer the choice of one of the following drugs in addition to the step one treatment: an ACE inhibitor or an ARB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults of black African or African–Caribbean family origin who do not have type 2 diabetes taking step one treatment, consider an ARB, in preference to an ACE inhibitor, in addition to step one treatment.</li> </ul> <p><u>Step three treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering step three treatment, review the person’s medications to ensure they are being taken at the optimal doses and discuss adherence (see recommendation under step two).</li> <li>• If hypertension is not controlled in adults taking step two treatment, offer a combination of an ACE inhibitor or ARB and a CCB and a thiazide-like diuretic.</li> </ul> <p><u>Step four treatment</u></p> <ul style="list-style-type: none"> <li>• If hypertension is not controlled in adults taking the optimal tolerated doses of an ACE inhibitor or an ARB plus a CCB and a thiazide-like diuretic, regard them as having resistant hypertension.</li> <li>• Before considering further treatment for a person with resistant hypertension, confirm elevated clinic blood pressure measurements using ambulatory or home blood pressure recordings, assess for postural hypotension, and discuss adherence.</li> <li>• For people with confirmed resistant hypertension, consider adding a fourth antihypertensive drug as step four treatment or seeking specialist advice.</li> <li>• Consider further diuretic therapy with low-dose spironolactone for adults with resistant hypertension starting step four treatment who have a blood potassium level of 4.5 mmol/l or less. Use particular caution in people with a reduced estimated glomerular filtration rate because they have an increased risk of hyperkalemia.</li> <li>• When using further diuretic therapy for step four treatment of resistant hypertension, monitor blood sodium and potassium and renal function within one month of starting treatment and repeat as needed thereafter.</li> <li>• Consider an alpha-blocker or beta-blocker for adults with resistant hypertension starting step four treatment who have a blood potassium level of more than 4.5 mmol/l.</li> <li>• If blood pressure remains uncontrolled in people with resistant hypertension taking the optimal tolerated doses of four drugs, seek specialist advice.</li> </ul>
<p>International Society on Hypertension in Blacks: <b>Management of High Blood Pressure in Blacks (2010)</b><sup>16</sup></p>	<ul style="list-style-type: none"> <li>• To attain and maintain blood pressure (BP) below target levels, multiple antihypertensive drugs will be required in most hypertensive blacks.</li> <li>• Use of two-drug combination therapy when SBP is &gt;15 mm Hg and/or DBP is &gt;10 mm Hg above goal levels is increasingly recommended as first-line therapy.</li> <li>• Two-drug regimens have generally contained a thiazide-type diuretic; however,</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>the combination of a calcium channel blocker (CCB) with either an ACE inhibitor or an ARB has been shown equally efficacious in BP lowering but with demonstrated superiority (CCB+ACE) for hard clinical outcomes compared with the same ACE inhibitor plus a thiazide-type diuretic.</p> <ul style="list-style-type: none"> <li>• In secondary prevention patients, the combination therapy should include a drug(s) with the appropriate compelling indications.</li> <li>• Certain classes of antihypertensive medications, specifically diuretics and CCBs, lower BP on average more than <math>\beta</math>-blockers and renin-angiotensin system (RAS) blockers in black patients when used as monotherapies.</li> <li>• In the absence of compelling indications, when BP is near goal levels, monotherapy with a diuretic or a CCB is preferred.</li> <li>• Lifestyle modifications should be initiated in all patients with hypertension, whether or not pharmacotherapy is planned.</li> <li>• ACE inhibitors or ARBs are recommended as alternative monotherapy options in the treatment of hypertension in blacks. The rationale for their lower tier monotherapy recommendation is because they have consistently achieved lesser average reductions in BP relative to that observed with monotherapy using either a diuretic or CCB.</li> </ul>
<p>Kidney Disease Improving Clinical Outcomes Group; <b>KDIGO Clinical Practice Guideline for the Management of Blood Pressure in Chronic Kidney Disease (2021)</b><sup>17</sup></p>	<p><u>Blood pressure measurement</u></p> <ul style="list-style-type: none"> <li>• The Work Group recommends standardized office blood pressure (BP) measurement in preference to routine office BP measurements for the management of high BP in adults.</li> <li>• The Work Group suggests that out-of-office BP measurements with ambulatory BP monitoring (ABPM) or home BP monitoring (HBPM) be used to complement standardized office BP readings for the management of high BP.</li> </ul> <p><u>Lifestyle interventions for lowering BP in patients with chronic kidney disease (CKD) not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>• The Work Group suggests targeting a sodium intake &lt;2 grams of sodium per day (or &lt;90 mmol of sodium per day, or &lt;5 grams of sodium chloride per day) in patients with high BP and CKD.</li> <li>• The Work Group suggests that patients with high BP and CKD be advised to undertake moderate-intensity physical activity for a cumulative duration of at least 150 minutes per week, or to a level compatible with their cardiovascular and physical tolerance.</li> </ul> <p><u>BP management in patients with CKD, with or without diabetes, not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>• The Work Group suggests that adults with high BP and CKD be treated with a target systolic BP (SBP) of &lt;120 mmHg, when tolerated, using standardized office BP measurement.</li> <li>• The Work Group recommends starting renin-angiotensin-system inhibitors (RASi) (angiotensin-converting enzyme inhibitor [ACEi] or angiotensin II receptor blocker [ARB]) for people with high BP, CKD, and severely increased albuminuria without diabetes.</li> <li>• The Work Group suggests starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately increased albuminuria without diabetes.</li> <li>• The Work Group recommends starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately-to-severely increased albuminuria with diabetes.</li> <li>• The Work Group recommends avoiding any combination of ACEi, ARB, and direct renin inhibitor (DRI) therapy in patients with CKD, with or without diabetes.</li> </ul> <p><u>BP management in kidney transplant recipients</u></p> <ul style="list-style-type: none"> <li>• Treat adult kidney transplant recipients with high BP to a target BP of &lt;130</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>mmHg systolic and &lt;80 mmHg diastolic using standardized office BP measurement.</p> <ul style="list-style-type: none"> <li>The Work Group recommends that a dihydropyridine calcium channel blocker (CCB) or an ARB be used as the first-line antihypertensive agent in adult kidney transplant recipients.</li> </ul> <p><b>BP management in children with CKD</b></p> <ul style="list-style-type: none"> <li>The Work Group suggests that in children with CKD, 24-hour mean arterial pressure by ABPM should be lowered to &lt;50<sup>th</sup> percentile for age, sex, and height.</li> </ul>
<p>American College of Cardiology/ American Heart Association Task Force: <b>Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults (2017)</b><sup>18</sup></p>	<p><u>Initiation of Blood Pressure (BP) Treatment for Overall Cardiovascular Disease (CVD) Risk</u></p> <ul style="list-style-type: none"> <li>Use of BP-lowering medications is recommended for secondary prevention of recurrent CVD events in patients with clinical CVD and an average systolic blood pressure (SBP) <math>\geq 130</math> mmHg or an average diastolic blood pressure (DBP) of <math>\geq 80</math> mmHg and for primary prevention in adults with an estimated 10-year atherosclerotic cardiovascular disease (ASCVD) risk of <math>\geq 10\%</math> and an average SBP of <math>\geq 130</math> mmHg or an average <math>\geq 80</math> mmHg.</li> <li>Use of BP-lowering medication is recommended for primary prevention of CVD in adults with no history of CVD and with an estimated 10-year ASCVD risk <math>&lt; 10\%</math> and an SBP of <math>\geq 140</math> mmHg or a DBP of <math>\geq 90</math> mmHg.</li> <li>Simultaneous use of an angiotensin converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), and/or renin inhibitor is potentially harmful and is not recommended to treat adults with hypertension.</li> <li>For adults with confirmed hypertension and known CVD or 10-year ASCVD risk of <math>\geq 10\%</math>, a BP target <math>&lt; 130/80</math> mmHg is recommended. For adults with confirmed hypertension without additional markers of increased CVD risk, a BP target <math>&lt; 130/80</math> mmHg may be reasonable.</li> <li>For initiation of antihypertensive drug therapy, first-line agents include thiazide diuretics, calcium channel blockers (CCBs), and ACE inhibitors or ARBs.</li> <li>Initiation of antihypertensive drug therapy with two first-line agents of different classes, either as separate agents or in a fixed-dose combination, is recommended in adults with stage 2 hypertension and an average BP <math>&gt; 20/10</math> mmHg above their BP target.</li> <li>Initiation of antihypertensive drug therapy with a single antihypertensive drug is reasonable in adults with stage 1 hypertension and BP goal <math>&lt; 130/80</math> mmHg with dosage titration and sequential addition of other agents to achieve the BP target.</li> </ul> <p><u>Stable Ischemic Heart Disease (SIHD)</u></p> <ul style="list-style-type: none"> <li>In adults with SIHD and hypertension, a BP target <math>&lt; 130/80</math> is recommended.</li> <li>Adults with SIHD and hypertension (BP <math>\geq 130/80</math> mmHg) should be treated with medications [e.g., guideline-directed medical therapy (GDMT) beta-blockers, ACE inhibitors, or ARBs] for compelling indications [e.g., previous myocardial infarction (MI), stable angina] as first-line therapy, with the addition of other drugs (e.g., dihydropyridine CCBs, thiazide diuretics, and/or mineralocorticoid receptor antagonists) as needed to further control hypertension.</li> <li>In adults with SIHD with angina and persistent uncontrolled hypertension, the addition of dihydropyridine CCBs to GDMT beta-blockers is recommended.</li> <li>In adults who have had a MI or acute coronary syndrome, it is reasonable to continue GDMT beta-blockers beyond three years as long-term therapy for hypertension.</li> <li>Beta-blockers and/or CCBs might be considered to control hypertension in patients with coronary artery disease (CAD) had an MI more than three years ago and have angina.</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><u>Heart Failure</u></p> <ul style="list-style-type: none"> <li>• In adults with increased risk of HF, the optimal BP in those with hypertension should be &lt;130 mmHg.</li> <li>• Adults with HFrEF and hypertension should be prescribed GDMT titrated to attain a BP &lt;130/80 mmHg.</li> <li>• Non-dihydropyridine CCBs are not recommended in the treatment of hypertension in adults with HFrEF.</li> <li>• In adults with HFpEF who present with symptoms of volume overload, diuretics should be prescribed to control hypertension.</li> <li>• Adults with HFpEF and persistent hypertension after management of volume overload should be prescribed ACE inhibitors or ARBs and beta-blockers titrated to attain SBP &lt;130 mmHg.</li> </ul> <p><u>CKD</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and CKD should be treated to a BP goal &lt;130/80 mmHg.</li> <li>• In adults with hypertension and CKD [stage 3 or higher or stage 1 or 2 with albuminuria (<math>\geq 300</math> mg/d, or <math>\geq 300</math> mg/g albumin-to-creatinine ratio or the equivalent in the first morning void)], treatment with an ACE inhibitor is reasonable to slow kidney disease progression. Treatment with an ARB may be reasonable if an ACE inhibitor is not tolerated.</li> <li>• After kidney transplantation, it is reasonable to treat patients with hypertension to a BP goal &lt;130/80 mmHg and with a CCB on the basis of improved glomerular filtration rate (GFR) and kidney survival.</li> </ul> <p><u>Cerebrovascular Disease</u></p> <ul style="list-style-type: none"> <li>• In adults with intracerebral hemorrhage (ICH) who present with SBP &gt;220 mmHg, it is reasonable to use continuous intravenous (IV) drug infusion and close BP monitoring to lower levels. Immediate lowering of SBP to &lt;140 mmHg in adults with spontaneous ICH who present within six hours of the acute event and have an SBP between 150 mmHg and 220 mmHg is not of benefit to reduce death or severe disability and can be potentially harmful.</li> <li>• Adults with acute ischemic stroke and elevated BP who are eligible for treatment with IV tissue plasminogen activator (tPA) should have their BP slowly lowered to &lt;185/110 mmHg before thrombolytic therapy is initiated.</li> <li>• In adults with an acute ischemic stroke, BP should be &lt;185/110 mmHg before administration of IV tPA and should be maintained below 180/105 mmHg for at least the first 24 hours after initiation drug therapy.</li> <li>• Starting or restarting antihypertensive therapy during hospitalization in patients with BP &gt;140/90 mmHg who are neurologically stable is safe and reasonable to improve long-term BP control, unless contraindicated.</li> <li>• In patient with BP <math>\geq 220/120</math> mmHg who did not receive IV alteplase or endovascular treatment and have no comorbid conditions requiring acute antihypertensive treatment, the benefit of initiating or reinitiating treatment of hypertension within the first 48 to 72 hours is uncertain. It might be reasonable to lower BP by 15% during the first 24 hours after onset of stroke. In patients with BP &lt;220/120 mmHg with the same conditions, initiating or reinitiating treatment of hypertension within the first 48 to 72 hours after an acute ischemic stroke is not effective to prevent death or dependency.</li> <li>• Adults with previously treated stroke or transient ischemic attack should be restarted on antihypertensive treatment after the first few days of the index event to reduce the risk of recurrent stroke and other vascular events. Treatment with a thiazide diuretic, ACE inhibitor, or ARB, or combination treatment consisting of a thiazide diuretic plus ACE inhibitor, is useful.</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• Adults not previously treated for hypertension who experienced a stroke or transient ischemic attack and have an established BP <math>\geq 140/90</math> mmHg should be prescribed antihypertensive treatment a few days after the index event to reduce the risk of recurrent stroke and other vascular event.</li> <li>• For adults who experience a stroke or transient ischemic attack, selection of specific drugs should be individualized on the basis of patient comorbidities and agent pharmacological class.</li> <li>• For adults who experience a stroke or transient ischemic attack, a BP goal <math>&lt;130/80</math> mmHg may be reasonable.</li> <li>• For adults with a lacunar stroke, a target SBP goal <math>&lt;130</math> mmHg may be reasonable.</li> <li>• In adults previously untreated for hypertension who experience an ischemic stroke or transient ischemic attack and have an SBP <math>&lt;140</math> mmHg and a DBP <math>&lt;90</math> mmHg, the usefulness of initiating antihypertensive treatment is not well established.</li> </ul> <p><u>Peripheral Artery Disease (PAD)</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and PAD should be treated similarly to patients with hypertension without PAD.</li> </ul> <p><u>Diabetes Mellitus (DM)</u></p> <ul style="list-style-type: none"> <li>• In adults with DM and hypertension, antihypertensive drug treatment should be initiated at a BP of <math>\geq 130/80</math> mmHg with a treatment goal <math>&lt;130/80</math> mmHg.</li> <li>• In adults with DM and hypertension, all first-line classes of antihypertensive agents (i.e., diuretics, ACE inhibitors, ARBs, and CCBs) are useful and effective.</li> <li>• In adults with DM and hypertension, ACE inhibitors or ARBs may be considered in the presence of albuminuria.</li> </ul> <p><u>Atrial Fibrillation, Valvular Heart Disease, and Aortic disease</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension can be useful for prevention of recurrence of AF.</li> <li>• In adults with asymptomatic aortic stenosis, hypertension should be treated with pharmacotherapy, starting at a low dose and gradually titrating upward as needed.</li> <li>• In patients with chronic aortic insufficiency, treatment of systolic hypertension with agents that do not slow the heart rate (i.e., avoid beta-blockers) is reasonable.</li> <li>• Beta-blockers are recommended as the preferred antihypertensive agents in patients with hypertension and thoracic aortic disease.</li> </ul> <p><u>Racial and Ethnic Differences in Treatment</u></p> <ul style="list-style-type: none"> <li>• In black adults with hypertension but without HF or CKD, including those with DM, initial antihypertensive treatment should include a thiazide-type diuretic or CCB. Two or more antihypertensive medications are recommended to achieve a BP target <math>&lt;130/80</math> mmHg in most adults with hypertension, especially in black adults with hypertension.</li> </ul> <p><u>Pregnancy</u></p> <ul style="list-style-type: none"> <li>• Women with hypertension who become pregnant, or are planning to become pregnant, should be transitioned to methyldopa, nifedipine, and/or labetalol during pregnancy.</li> <li>• Women with hypertension who become pregnant should not be treated with ACE inhibitors, ARBs, or direct renin inhibitors.</li> </ul> <p><u>Older Persons</u></p>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• Treatment of hypertension with an SBP treatment goal &lt;130 mmHg is recommended for noninstitutionalized ambulatory community-dwelling adults (≥65 years of age) with an average SBP of ≥130 mmHg.</li> <li>• For older adults (≥65 years of age) with hypertension and a higher burden of comorbidity and limited life expectancy, clinical judgment, patient preference, and a team-based approach to assess risk/benefit is reasonable for decisions regarding intensity of BP lowering and choice of antihypertensive drugs.</li> </ul> <p><u>Hypertensive Crises</u></p> <ul style="list-style-type: none"> <li>• In adults with a hypertensive emergency, admission to an intensive care unit is recommended for continuous monitoring of BP and target organ damage and for parenteral administration of an appropriate agent.</li> <li>• For adults with a compelling condition (i.e., aortic dissection, severe pre-eclampsia or eclampsia, or pheochromocytoma crisis), SBP should be reduced to &lt;140 mmHg during the first hour and to &lt;120 mmHg in aortic dissection.</li> <li>• For adults without a compelling condition, SBP should be reduced by no more than 25% within the first hours; then, if stable, to 160/100 mmHg within the next two to six hours; and then cautiously to normal during the following 24 to 48 hours.</li> </ul> <p><u>Cognitive Decline and Dementia</u></p> <ul style="list-style-type: none"> <li>• In adults with hypertension, BP lowering is reasonable to prevent cognitive decline and dementia.</li> </ul> <p><u>Patients Undergoing Surgical Procedures</u></p> <ul style="list-style-type: none"> <li>• In patients with hypertension undergoing major surgery who have been on beta-blockers chronically, beta-blockers should be continued.</li> <li>• In patients with hypertension undergoing planned elective major surgery, it is reasonable to continue medical therapy for hypertension until surgery.</li> <li>• In patients with hypertension undergoing major surgery, discontinuation of ACE inhibitors or ARBs perioperatively may be considered.</li> <li>• In patients with planned elective major surgery and SBP ≥180 mmHg or DBP ≥110 mmHg, deferring surgery may be considered.</li> <li>• For patients undergoing surgery, abrupt pre-operative discontinuation of beta-blockers or clonidine is potentially harmful.</li> <li>• Beta-blockers should not be started on the day of surgery in beta-blocker-naïve patients.</li> <li>• Patients with intraoperative hypertension should be managed with IV medications until such time as oral medications can be resumed.</li> </ul>
<p>American Diabetes Association: <b>Standards of Medical Care in Diabetes (2022)</b><sup>19</sup></p>	<p><u>Hypertension/blood pressure control</u></p> <ul style="list-style-type: none"> <li>• Blood pressure should be measured at every routine visit. When possible, patients found to have elevated blood pressure (≥140/90) should have blood pressure confirmed using multiple readings, including measurements on a separate day, to diagnose hypertension. Patients with blood pressure ≥180/110 and cardiovascular disease could be diagnosed with hypertension at a single visit.</li> <li>• All hypertensive patients with diabetes should monitor their blood pressure at home.</li> <li>• For patients with diabetes and hypertension, with diabetes and hypertension, blood pressure targets should be individualized through a shared decision-making process that addresses cardiovascular risk, potential adverse effects of antihypertensive medications, and patient preferences.</li> <li>• For individuals with diabetes and hypertension at higher cardiovascular risk (existing atherosclerotic cardiovascular disease [ASCVD] or 10-year ASCVD risk ≥15%), a blood pressure target of &lt;130/80 mmHg may be appropriate, if it</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>can be safely attained.</p> <ul style="list-style-type: none"> <li>• For individuals with diabetes and hypertension at lower risk for cardiovascular disease (10-year atherosclerotic cardiovascular disease risk &lt;15%), treat to blood pressure target of &lt;140/90.</li> <li>• In pregnant patients with diabetes and preexisting hypertension, a blood pressure target of 110 to 135/85 is suggested in the interest of reducing the risk for accelerated maternal hypertension and minimizing impaired fetal growth.</li> <li>• For patients with blood pressure &gt;120/80, lifestyle intervention consists of weight loss when indicated, a Dietary Approaches to Stop Hypertension (DASH)-style eating pattern including reducing sodium and increasing potassium intake, moderation of alcohol intake, and increased physical activity.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq</math>140/90 mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of pharmacologic therapy to achieve blood pressure goals.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq</math>160/100 mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of two drugs or a single pill combination of drugs demonstrated to reduce cardiovascular events in patients with diabetes.</li> <li>• Treatment for hypertension should include drug classes demonstrated to reduce cardiovascular events in patients with diabetes (ACE inhibitors, angiotensin receptor blockers, thiazide-like diuretics, or dihydropyridine calcium channel blockers). ACE inhibitors or angiotensin receptor blockers are recommended first-line therapy for hypertension in people with diabetes and coronary artery disease.</li> <li>• Multiple-drug therapy is generally required to achieve blood pressure targets (but not a combination of ACE inhibitors and angiotensin receptor blockers).</li> <li>• An ACE inhibitor or angiotensin receptor blocker, at the maximum tolerated dose indicated for blood pressure treatment, is the recommended first-line treatment for hypertension in patients with diabetes and urinary albumin-to-creatinine ratio <math>\geq</math>300 mg/g creatinine or 30 to 299 mg/g creatinine. If one class is not tolerated, the other should be substituted.</li> <li>• For patients treated with an ACE inhibitor, angiotensin receptor blocker, or diuretic, serum creatinine/estimated glomerular filtration rate and serum potassium levels should be monitored at least annually.</li> <li>• Patients with hypertension who are not meeting blood pressure targets on three classes of antihypertensive medications (including a diuretic) should be considered for mineralocorticoid receptor antagonist therapy.</li> </ul> <p><b>Chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>• At least once a year, assess urinary albumin (e.g., spot urinary albumin-to-creatinine ratio) and estimated glomerular filtration rate in patients with type 1 diabetes with duration of five or more years and in all patients with type 2 diabetes.</li> <li>• Patients with diabetes and urinary albumin <math>\geq</math>300 mg/g creatinine and/ or an estimated glomerular filtration rate 30 to 60 mL/min/1.73 m<sup>2</sup> should be monitored twice annually to guide therapy.</li> <li>• Optimize glucose control to reduce the risk or slow the progression of chronic kidney disease (CKD).</li> <li>• For patients with type 2 diabetes and diabetic kidney disease, use of a sodium-glucose cotransporter 2 inhibitor in patients with an estimated glomerular filtration rate <math>\geq</math>25 mL/min/1.73 m<sup>2</sup> and urinary albumin <math>\geq</math>300 mg/g creatinine is recommended to reduce CKD progression and cardiovascular events.</li> <li>• In patients with type 2 diabetes and CKD, consider use of sodium-glucose cotransporter 2 inhibitors additionally for cardiovascular risk reduction when estimated glomerular filtration rate and urinary albumin creatinine are <math>\geq</math>25</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>mL/min/1.73 m<sup>2</sup> or ≥300 mg/g, respectively.</p> <ul style="list-style-type: none"> <li>• In patients with CKD who are at increased risk for cardiovascular events or CKD progression and are unable to use a sodium–glucose cotransporter 2 inhibitor, a nonsteroidal mineralocorticoid receptor antagonist (finerenone) is recommended to reduce CKD progression and cardiovascular events.</li> <li>• Optimize blood pressure control and reduce blood pressure variability to reduce the risk or slow the progression of CKD.</li> <li>• Do not discontinue renin-angiotensin system blockade for minor increases in serum creatinine (≤30%) in the absence of volume depletion.</li> <li>• For people with nondialysis-dependent stage 3 or higher CKD, dietary protein intake should be a maximum of 0.8 g/kg body weight per day (the recommended daily allowance). For patients on dialysis, higher levels of dietary protein intake should be considered, since malnutrition is a major problem in some dialysis patients.</li> <li>• In nonpregnant patients with diabetes and hypertension, either an ACE inhibitor or an angiotensin receptor blocker is recommended for those with modestly elevated urinary albumin–to–creatinine ratio (30 to 299 mg/g creatinine) and is strongly recommended for those with urinary albumin–to–creatinine ratio ≥300 mg/g creatinine and/or estimated glomerular filtration rate &lt;60 mL/min/1.73 m<sup>2</sup>.</li> <li>• Periodically monitor serum creatinine and potassium levels for the development of increased creatinine or changes in potassium when ACE inhibitors, angiotensin receptor blockers, or diuretics are used.</li> <li>• An ACE inhibitor or an angiotensin receptor blocker is not recommended for the primary prevention of CKD in patients with diabetes who have normal blood pressure, normal urinary albumin–to–creatinine ratio (&lt;30 mg/g creatinine), and normal estimated glomerular filtration rate.</li> <li>• Patients should be referred for evaluation by a nephrologist if they have an estimated glomerular filtration rate &lt;30 mL/min/1.73 m<sup>2</sup>.</li> <li>• Promptly refer to a nephrologist for uncertainty about the etiology of kidney disease, difficult management issues, and rapidly progressing kidney disease.</li> </ul>

### III. Indications

The Food and Drug Administration (FDA)-approved indications for the potassium-sparing diuretics are noted in Table 3. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 3. FDA-Approved Indications for the Potassium-Sparing Diuretics<sup>1-4</sup>**

Indication(s)	Single Entity Agents		Combination Products	
	Amiloride	Triamterene	Amiloride and HCTZ	Triamterene and HCTZ
<b>Congestive Heart Failure (or Edema) and Hypertension</b>				
Help restore normal serum potassium levels in patients who develop hypokalemia on the kaliuretic diuretic	✓ *			
Prevent development of hypokalemia in patients who would be exposed to particular risk if hypokalemia were to develop	✓ *			
Treatment of edema associated with congestive heart failure, cirrhosis of the liver and the nephrotic syndrome; steroid-induced edema,		✓ †		

Indication(s)	Single Entity Agents		Combination Products	
	Amiloride	Triamterene	Amiloride and HCTZ	Triamterene and HCTZ
idiopathic edema and edema due to secondary hyperaldosteronism				
Use in patients who develop hypokalemia when thiazide or other kaliuretic diuretics are used alone, or in whom maintenance of normal serum potassium levels is considered to be clinically important			✓ ‡	
Use in patients who develop hypokalemia on hydrochlorothiazide alone, or in whom require a thiazide diuretic and in whom the development of hypokalemia cannot be risked				✓ ‡

\*As adjunctive treatment with thiazide diuretics or other kaliuretic-diuretic agents.

†May be used alone or with other diuretics, either for its added diuretic effect or its potassium-sparing potential.

‡The fixed combination drug is not indicated for the initial therapy of edema or hypertension except in individuals in whom the development of hypokalemia cannot be risked.

HCTZ=hydrochlorothiazide

#### IV. Pharmacokinetics

The pharmacokinetic parameters of the potassium-sparing diuretics are listed in Table 4.

**Table 4. Pharmacokinetic Parameters of the Potassium-Sparing Diuretics<sup>6</sup>**

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life (hours)
<b>Single Entity Agents</b>					
Amiloride	30 to 90	Not significant (% not reported)	Not metabolized	Feces (40 to 50) Renal (50)	6 to 9
Triamterene	30 to 70	55 to 67	Liver (80)	Renal (21)	1.5 to 2.5
<b>Combination Products</b>					
Amiloride and HCTZ	30 to 90/60 to 80	Not significant (% not reported)/ 10	Not metabolized	Feces (40 to 50) Renal (50)/ Renal (>60)	6 to 9/ 10 to 12
Triamterene and HCTZ	30 to 70/60 to 80	55 to 67/40	Liver (80)/ not reported	Renal (21)/ Renal (>60)	1.5 to 2.5/ 10 to 12

HCTZ=hydrochlorothiazide

#### V. Drug Interactions

Major drug interactions with the potassium-sparing diuretics are listed in Table 5.

**Table 5. Major Drug Interactions with the Potassium-Sparing Diuretics<sup>6</sup>**

Generic Name(s)	Interaction	Mechanism
Potassium-sparing diuretics (amiloride, triamterene)	Aldosterone blockers	Aldosterone blockers and potassium-sparing diuretics may exert additive pharmacologic effects. Hyperkalemia with the potential for cardiac arrhythmias may result.
Potassium-sparing diuretics (amiloride, triamterene)	Potassium preparations	Use of potassium preparations and potassium-sparing diuretics may increase the risk of hyperkalemia. Cardiac arrhythmias or cardiac arrest may occur.
Potassium-sparing diuretics (amiloride, triamterene)	ACE inhibitors	Hyperkalemia, possibly with cardiac arrhythmias or arrest may occur with the combination of amiloride and ACE inhibitors. Decreased aldosterone activity by ACE inhibitors may function synergistically with potassium

Generic Name(s)	Interaction	Mechanism
		conservation by amiloride to produce substantial hyperkalemia.
Potassium-sparing diuretics (amiloride, triamterene)	Indomethacin and derivatives	The combination of indomethacin and derivatives and triamterene may cause a sudden onset of nephrotoxicity.
Potassium-sparing diuretics (amiloride)	ARBs	The risk of hyperkalemia may be increased when amiloride is co-administered with ARBs. Decreased aldosterone activity by ARBs may function synergistically with potassium conservation by amiloride to produce substantial hyperkalemia.
Thiazide diuretics (HCTZ)	Dofetilide	Thiazide diuretics increase potassium excretion. Hypokalemia may occur, increasing the risk of torsades de pointes.
Thiazide diuretics (HCTZ)	Lithium	Thiazide diuretics decrease the renal clearance of lithium which leads to increased serum lithium levels. Lithium toxicity has occurred.
Potassium-sparing diuretics (amiloride)	Aliskiren	Hyperkalemia risk may be increased when aliskiren is coadministered with potassium-sparing diuretics. Decreased aldosterone activity by aliskiren may function synergistically with potassium conservation leading to the development of hyperkalemia.
Potassium-sparing diuretics (amiloride)	Macrolide immunosuppressants	Macrolide immunosuppressives and potassium-sparing diuretics may exert additive effects on potassium leading to hyperkalemia.
Thiazide diuretics (HCTZ)	Diazoxide	Hyperglycemia may occur with symptoms similar to diabetes. The mechanism is unknown.
Thiazide diuretics (HCTZ)	Digitalis glycosides	Diuretic-induced electrolyte disturbances may predispose the patient to digitalis-induced cardiac arrhythmias.

ACE inhibitor=angiotensin converting enzyme inhibitor, ARB=angiotensin II receptor blocker, HCTZ=hydrochlorothiazide

## VI. Adverse Drug Events

The most common adverse drug events reported with the potassium-sparing diuretics are listed in Table 6. The boxed warnings are listed in Tables 7 through 9.

**Table 6. Adverse Drug Events (%) Reported with the Potassium-Sparing Diuretics<sup>1-6</sup>**

**Table 7. Boxed Warning for Amiloride<sup>5</sup>**

<b>WARNING</b>
Like other potassium-conserving agents, amiloride may cause hyperkalemia (serum potassium levels greater than 5.5 mEq per liter) which, if uncorrected, is potentially fatal. Hyperkalemia occurs commonly (about 10%) when amiloride is used without a kaliuretic diuretic. This incidence is greater in patients with renal impairment, diabetes mellitus (with or without recognized renal insufficiency), and in the elderly. When amiloride is used concomitantly with a thiazide diuretic in patients without these complications, the risk of hyperkalemia is reduced to about 1 to 2%. It is thus essential to monitor serum potassium levels carefully in any patient receiving amiloride, particularly when it is first introduced, at the time of diuretic dosage adjustments, and during any illness that could affect renal function.

**Table 8. Boxed Warning for Triamterene-Hydrochlorothiazide<sup>5</sup>**

<b>WARNING</b>
Abnormal elevation of serum potassium levels (at least 5.5 mEq/L) can occur with all potassium-sparing agents, including triamterene. Hyperkalemia is more likely to occur in patients with renal impairment and diabetes (even without evidence of renal impairment), and in elderly or severely ill patients. Because uncorrected hyperkalemia may be fatal, serum potassium levels must be monitored at frequent intervals especially in patients receiving triamterene, when dosages are changed, or with any illness that may influence renal function.

**Table 9. Boxed Warning for Amiloride and Hydrochlorothiazide<sup>5</sup>**

<b>WARNING</b>
Like other potassium-conserving diuretic combinations, amiloride and hydrochlorothiazide may cause hyperkalemia (serum potassium levels greater than 5.5 mEq per liter). In patients without renal impairment or diabetes mellitus, the risk of hyperkalemia with this combination product is about 1 to 2 percent. This risk is higher in patients with renal impairment or diabetes mellitus (even without recognized diabetic nephropathy). Since hyperkalemia, if uncorrected, is potentially fatal, it is essential to monitor serum potassium levels carefully in any patient receiving amiloride hydrochloride and hydrochlorothiazide, particularly when it is first introduced, at the time of dosage adjustments, and during any illness that could affect renal function.

## VII. Dosing and Administration

The usual dosing regimens for the potassium-sparing diuretics are listed in Table 10.

**Table 10. Usual Dosing Regimens for the Potassium-Sparing Diuretics<sup>1-6</sup>**

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
-----------------	------------------	----------------------	--------------

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
<b>Single Entity Agents</b>			
Amiloride	<u>Congestive heart failure (or edema) and hypertension:</u> Tablet: initial, 5 mg daily; may increase to 10 mg daily if needed; maximum, 20 mg	Safety and efficacy in children have not been established.	Tablet: 5 mg
Triamterene	<u>Treatment of edema:</u> Capsule: initial, 100 mg twice daily; maximum, 300 mg	Safety and efficacy in children have not been established.	Capsule: 50 mg 100 mg
<b>Combination Products</b>			
Amiloride and HCTZ	<u>Congestive heart failure (or edema) and hypertension:</u> Tablet: initial, 5-50 mg once daily; maintenance, 5-50 to 10-100 mg once daily or in divided doses	Safety and efficacy in children have not been established.	Tablet: 5-50 mg
Triamterene and HCTZ	<u>Congestive heart failure (or edema) and hypertension:</u> Capsule, tablet: initial, 37.5-25 mg once daily; maintenance: 37.5-25 to 75-50 mg once daily	Safety and efficacy in children have not been established.	Capsule: 37.5-25 mg  Tablet: 37.5-25 mg 75-50 mg

HCTZ=hydrochlorothiazide

## VIII. Effectiveness

Clinical studies evaluating the safety and efficacy of the potassium-sparing diuretics are summarized in Table 11.

**Table 11. Comparative Clinical Trials with the Potassium-Sparing Diuretics**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<b>Edema/Heart Failure</b>				
Bayliss et al. <sup>20</sup> (1987)  Amiloride 5 mg QD and furosemide 40 mg	OS  Patients with heart failure, 22 to 75 years of age, referred with breathlessness on moderate exertion (NYHA class 2 to 3) who were not previously treated	N=12  1 month	Primary: Average weight, heart rate at rest and maximal exercise, maximal treadmill exercise time, plasma renin, plasma aldosterone, noradrenaline at rest and maximal exercise  Secondary: Not reported	Primary: Average weight was significantly reduced during treatment from 72.4 to 68.5 kg (P=0.0003).  Resting heart rate decreased from 89 to 75 bpm (P=0.03). There was no significant change during exercise.  Maximal treadmill exercise time significantly increased from 9.1 to 17.6 minutes (P=0.007).  Plasma concentrations of renin increased from 1.1 to 4.2 ng/mL/hr at rest and from 2.5 to 11.3 ng/mL/hr upon exercise (P<0.007).  Plasma concentrations of aldosterone increased from 169 to 488 pmol/L at rest and from 223 to 737 pmol/L upon exercise (P<0.007).  Plasma concentrations of noradrenaline were significantly reduced (decreased to within normal ranges) at rest following treatment (P=0.005) but remained abnormally high at maximal exercise following treatment.  Secondary: Not reported
Rengo et al. <sup>21</sup> (1979)  Amiloride 15 mg QD  vs  amiloride and	RCT  Patients 35 to 60 years of age with liver cirrhosis and ascites or CHF	N=30  15 days	Primary: Body weight, 24 hour diuresis, serum sodium, serum potassium, sodium and potassium urinary loss	Primary: All treatment groups had a significant reduction in body weight from baseline (P<0.001 for all). Amiloride and HCTZ-treated patients achieved a significantly greater reduction compared to amiloride-treated patients (P<0.001).  All treatment groups significantly differed from baseline in 24 hour diuresis (P<0.01). Amiloride and HCTZ- and HCTZ-treated patients achieved greater diuresis compared to amiloride-treated patients (P<0.001 for both).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>HCTZ 15-150 mg QD (fixed-dose combination product)</p> <p>vs</p> <p>HCTZ 150 mg QD</p>			<p>Secondary: Not reported</p>	<p>Serum sodium was reduced from baseline in all treatment groups. HCTZ-treated patients had a significantly greater reduction than amiloride- (P&lt;0.01) and amiloride and HCTZ-treated patients (P&lt;0.001). Sodium urinary loss was seen with all treatments at day two, amiloride and HCTZ therapy had maintained the loss at day five (P&lt;0.001 for both).</p> <p>Serum potassium decreased in HCTZ-treated patients but increased in amiloride- and amiloride and HCTZ-treated patients. HCTZ-treated patients had a marked increase in potassium urinary loss (P&lt;0.001).</p> <p>Secondary: Not reported</p>
<p>Cheitlin et al.<sup>22</sup> (1991)</p> <p>Amiloride 5 or 10 mg QD for 7 days, followed by placebo plus HCTZ 50 or 100 mg QD for 14 days</p> <p>vs</p> <p>placebo for 14 days, followed by amiloride 5 or 10 mg plus HCTZ 50 or 100 mg QD for the next 7 days</p>	<p>DB, PC, RCT, XO</p> <p>Patients with a history CHF and ≥1 episode of pulmonary edema (NYHA class 2 to 3) who were not previously treated</p>	<p>N=11</p> <p>21 days</p>	<p>Primary: Hemodynamic changes at rest and exercise</p> <p>Secondary: Not reported</p>	<p>Primary: At rest, there were no significant differences between placebo- and amiloride-treated patients in right atrial pressure, pulmonary atrial pressure, heart rate, pulmonary artery wedge pressure, systemic arterial pressure, right ventricular stroke work index, left ventricular stroke work index, systemic vascular resistance, cardiac index or stroke volume index (P values not reported).</p> <p>During exercise, there were significant differences between placebo- and amiloride-treated patients at the 50-watt stage in right atrial pressure (15.0 vs 10.5 mm Hg), pulmonary artery wedge pressure (28.6 vs 22.1 mm Hg), pulmonary artery diastolic pressure (32.2 vs 21.6 mm Hg), mean pulmonary artery pressure (44.4 vs 38.9 mm Hg), left ventricular stroke work index (69.5 vs 77.9 g-m/m<sup>2</sup>) and stroke volume index (44.9 vs 46.2 cc/beat/m<sup>2</sup>), respectively (P values not reported).</p> <p>There were no significant differences between placebo and amiloride therapy during exercise in right ventricular stroke work index, heart rate, aortic pressure, cardiac index and total systemic vascular resistance (P values not reported).</p> <p>Secondary: Not reported</p>
<p>Ghosh et al.<sup>23</sup> (1987)</p>	<p>PG, RCT, SB</p>	<p>N=60</p>	<p>Primary: Body weight,</p>	<p>Primary: Body weight was reduced with both treatments (P values not reported).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>Amiloride and HCTZ 2.5-25 mg QD (fixed-dose combination product)</p> <p>vs</p> <p>triamterene and HCTZ 50-25 mg QD (fixed-dose combination product)</p>	<p>Elderly patients with stable, mild to moderate CHF</p>	<p>8 weeks</p>	<p>clinical score, biochemistry</p> <p>Secondary: Not reported</p>	<p>Both treatments resulted in improvements in clinical scores; 95 and 88% of the amiloride/HCTZ- and triamterene/HCTZ-treated patients showed an improvement in heart failure signs with no patient's symptoms becoming worse (P values were not reported).</p> <p>Eighty five and 84% of amiloride/HCTZ- and triamterene/HCTZ-treated patients showed an improvement in heart failure symptoms (P values were not reported).</p> <p>There were no significant differences in serum sodium, potassium or urea between the two treatments (P values were not reported).</p> <p>Secondary: Not reported</p>
<p>Kohvakka.<sup>24</sup> (1998)</p> <p>HCTZ 50 mg BID</p> <p>vs</p> <p>amiloride 5 mg BID plus HCTZ 50 mg BID</p> <p>vs</p> <p>triamterene 75 mg BID plus HCTZ 50 mg BID</p> <p>vs</p> <p>KCl 1,000 mg BID plus HCTZ 50 mg BID</p>	<p>RCT, XO</p> <p>Patients 41 to 69 years of age with CHF (NYHA class 2 to 3) who developed persistent hypokalemia on HCTZ alone</p>	<p>N=25</p> <p>5 months</p>	<p>Primary: Changes in weight, blood pressure, serum sodium, serum potassium and total body potassium</p> <p>Secondary: Percentage with hypokalemia, median days until hypokalemia detection, serum magnesium</p>	<p>Primary: Weight loss was significant in amiloride plus HCTZ- and triamterene plus HCTZ-treated patients (P=0.05 for both), but not in KCl plus HCTZ-treated patients (P value not reported), compared to HCTZ-treated patients.</p> <p>No significant changes in blood pressure were observed (P values not reported).</p> <p>No differences in serum sodium were observed in amiloride plus HCTZ- or triamterene plus HCTZ-treated patients (P values not reported). Serum sodium levels were slightly higher in KCl plus HCTZ-patients compared to HCTZ-treated patients (P=0.01).</p> <p>Serum potassium was found to be significantly higher in all combination treated-patients compared to HCTZ-treated patients (P=0.01 for all comparisons). Total body potassium was significantly higher in amiloride plus HCTZ- and triamterene plus HCTZ-treated patients (P=0.05 for both), but not in KCl plus HCTZ-treated patients (P value not reported), compared to HCTZ-treated patients.</p> <p>Secondary: The percentages of patients that became hypokalemic were 39, 52 and 52% in</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>amiloride plus HCTZ-, triamterene plus HCTZ- and KCl plus HCTZ-treated patients (P values not reported).</p> <p>The median days until hypokalemia detection were 114.0, 75.0 and 51.5 for amiloride plus HCTZ-, triamterene plus HCTZ- and KCl plus HCTZ-treated patients (P values not reported).</p> <p>Serum magnesium was maintained at a significantly higher rate in amiloride plus HCTZ- and triamterene plus HCTZ- patients compared to KCl plus HCTZ-treated patients (P values not reported).</p>
<p>Faris et al.<sup>25</sup> (2006)</p> <p>Potassium-sparing diuretics (amiloride, triamterene), loop diuretics (furosemide, bumetanide), or thiazide diuretics (chlorothiazide)</p> <p>vs</p> <p>placebo or active control (ACE inhibitors, digoxin)</p>	<p>MA (14 trials)</p> <p>Adult patients with chronic heart failure</p>	<p>N=525</p> <p>2 to 52 weeks</p>	<p>Primary: Mortality</p> <p>Secondary: Effect of diuretic withdrawal on worsening of heart failure and exercise capacity</p>	<p>Primary: Pooled data from three PC trials (n=202) reporting on mortality revealed that mortality was lower for diuretic-treated patients compared to placebo-treated patients (2.7 vs 10.9%, respectively; OR, 0.24; 95% CI, 0.07 to 0.83; P=0.02). The difference represents an absolute risk reduction of 8% in mortality in diuretic-treated patients (NNT, 12.5).</p> <p>Secondary: Pooled data from two PC trials (n=169) reporting on the effect of diuretics on worsening heart failure revealed lower admission rates for worsening heart failure in diuretic-treated patients compared to placebo-treated patients (OR, 0.07; 95% CI, 0.01 to 0.52; P=0.01).</p> <p>Pooled data from two parallel RCTs (n=43) reporting on the effect of diuretics on exercise capacity revealed that diuretic therapy improved exercise capacity compared to active control (WMD, 0.74; 95% CI, 0.37 to 1.11; P&lt;0.0001). Pooled data from two XO RCTs (n=48) revealed similar results (WMD, 0.67; 95% CI, 0.02 to 1.31; P=0.04). In total (n=91), diuretic therapy improved exercise capacity in patients with chronic heart failure (WMD, 0.72; 95% CI, 0.40 to 1.04; P&lt;0.0001).</p>
<b>Hypertension</b>

The overall estimate showed no significant effect of potassium sparing diuretics on this outcomes (RR, 0.53; 95% CI, 0.19 to 1.51).</p>
<p>Multicenter Diuretic Cooperative Study Group<sup>27</sup> (1981)</p> <p>Amiloride 5 mg QD</p> <p>vs</p> <p>amiloride and HCTZ 5-50 mg QD (fixed-dose combination product)</p> <p>vs</p>	<p>DB, MC, RCT</p> <p>Patients 21 to 69 years of age with mild to moderate essential HTN (supine DBP 95 to 115 mm Hg)</p>	<p>N=179</p> <p>12 weeks</p>	<p>Primary: Change from baseline in average supine SBP and DBP</p> <p>Secondary: Heart rate, body weight, serum potassium</p>	<p>Primary: Baseline vs 12 week average supine blood pressure was 153/101 vs 139/93 for amiloride-, 160/100 vs 137/90 for amiloride and HCTZ- and 154/101 vs 134/89 mm Hg for HCTZ-treated patients. Reductions in supine blood pressure were significant with all treatments (P&lt;0.01). The SBP reduction was significantly greater with amiloride and HCTZ-treated patients compared to amiloride-treated patients at all weeks and HCTZ-treated patients at four and eight weeks (P&lt;0.05, both).</p> <p>Secondary: No significant changes from baseline in heart rate were observed in amiloride and HCTZ-treated patients (P values not reported). An increase in heart rate of 3.3 bpm was observed in these patients (P&lt;0.05).</p> <p>Changes in body weight from baseline were -1.17 kg in amiloride and HCTZ-, -0.72 kg in HCTZ- and 0.045 kg in amiloride-treated patients (P&lt;0.05, for amiloride plus HCTZ only).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
HCTZ 50 mg QD				Changes in serum potassium from baseline were 0.23 in amiloride- (P<0.01), -0.38 in amiloride and HCTZ- (P<0.01) and -0.59 mEq/L in HCTZ-treated patients (P<0.01). The change in HCTZ-treated patients was statistically greater than the change in the amiloride and HCTZ-treated patients (P<0.05). Twenty three, two and zero percent of HCTZ-, amiloride and HCTZ- and amiloride-treated patients experienced hypokalemia.
Salmela et al. <sup>28</sup> (1986)  Amiloride 2.5 mg/day and HCTZ 25 mg/day  vs  HCTZ 25 mg/day daily	DB, MC, PG, RCT  Adult patients with mild to moderate HTN	N=40  12 weeks	Primary: Changes in blood pressure  Secondary: Not reported	Primary: At the end of the first treatment period (four weeks), mean supine SBP and DBP was 161 and 91 mm Hg in amiloride plus HCTZ-treated patients (P<0.01 and P<0.001, respectively).  At the end of the first treatment period (four weeks), mean supine SBP and DBP was 165 and 96 mm Hg in HCTZ-treated patients (P<0.01 for both).  At the end of the second treatment period (eight weeks), mean supine SBP and DBP was 154 and 86 mm Hg in amiloride plus HCTZ-treated patients (P<0.01 and P<0.001).  At the end of the second treatment period (eight weeks), mean supine SBP and DBP was 155 and 90 mm Hg in HCTZ-treated patients (P<0.001 and P<0.001).  There were no significant differences in blood pressure reduction between the two treatments (P value not reported).  Secondary: Not reported
Hood et al. <sup>29</sup> (2007) SALT study  Amiloride 20 mg/day  vs  amiloride 40	DB, RCT, XO  Adult patients with seated blood pressure of 140/90 to 170/110 mm Hg, plasma renin of ≤12 mU/L, plasma aldosterone-renin	N=57  42 weeks	Primary: Change in blood pressure and plasma renin from baseline between spironolactone 100 mg/day and bendroflumethiazide 5 mg/day	Primary: Spironolactone 100 mg/day- and bendroflumethiazide 5 mg/day-treated patients did not exhibit a significant difference in blood pressure reduction from baseline (P value not reported).  Secondary: Spironolactone 50 mg/day-treated patients exhibited a significant decrease in blood pressure from baseline compared to bendroflumethiazide 2.5 mg/day-treated patients (P<0.01).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
mg/day vs spironolactone 50 mg/day vs spironolactone 100 mg/day vs bendroflumethiazide* 2.5 mg/day vs bendroflumethiazide* 5 mg/day vs losartan 100 mg/day vs placebo	ratio >750, previous fall in SBP $\geq$ 20 mm Hg after 1 month of OL treatment with spironolactone 50 mg/day		Secondary: Change in blood pressure and plasma renin from baseline between amiloride and other diuretics and between lower and higher doses of each diuretic	Losartan 100 mg-treated patients exhibited a significant decrease in blood pressure from baseline compared to bendroflumethiazide 2.5 mg/day-treated patients (P<0.05).  High-dose bendroflumethiazide- and amiloride-treated patients exhibited significantly greater reductions in blood pressure compared to the lower doses (P<0.05).  Spironolactone-treated patients exhibited a four-fold increase in baseline renin level compared to a two-fold increase observed in bendroflumethiazide-treated patients (P=0.003).
Kohvakka et al. <sup>30</sup> (1979)  Amiloride 5 mg QD	PC, RCT, XO  Patients 41 to 70 years of age with uncomplicated	N=31  3 months	Primary: Changes in blood pressure, serum potassium, sodium, creatinine, urate	Primary: No significant changes in blood pressure were observed with any of the treatments (P values not reported).  Mean serum potassium was reduced with all treatments except with

## IX. Cost

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of '\$' signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 11. Relative Cost of the Potassium-Sparing Diuretics**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost
<b>Single Entity Agents</b>				
Amiloride	tablet	N/A	N/A	\$
Triamterene	capsule	N/A	N/A	\$\$\$\$
<b>Combination Products</b>				
Amiloride and HCTZ	tablet	N/A	N/A	\$
Triamterene and HCTZ	capsule, tablet	Maxzide®*	\$\$\$	\$

\*Generic is available in at least one dosage form or strength.

HCTZ=hydrochlorothiazide, N/A=Not available

## X. Conclusions

The potassium-sparing diuretics are approved for the treatment of congestive heart failure, edema, and hypertension.<sup>1-4</sup> When used alone, potassium-sparing diuretics have a weak diuretic and antihypertensive effect and an increased risk of hyperkalemia. The potassium-sparing diuretics are generally used in combination with other diuretics to help restore normal serum potassium levels or to prevent the development of hypokalemia.<sup>1-4</sup> Amiloride and triamterene are available as a fixed-dose combination with hydrochlorothiazide. All of the products are available in a generic formulation.

For the treatment of chronic heart failure, guidelines recommend the use of diuretics in all patients who have evidence of volume overload. The loop diuretics are generally recommended as initial therapy in patients with left ventricular dysfunction. For those with persistent fluid retention despite treatment with a loop diuretic, a thiazide diuretic or metolazone may be added to the regimen. In patients with normal left ventricular function, either a thiazide diuretic or loop diuretic may be used as initial therapy to manage fluid overload.<sup>8-9</sup> As indicated by the FDA-approved indications of the potassium-sparing diuretics, these agents are typically used as adjunctive therapy in patients receiving thiazide diuretics to prevent the development of hypokalemia or to restore normal serum potassium levels.<sup>1-4</sup> Triamterene may be used along or with other diuretics, either for its added diuretic effect or its potassium-sparing potential.<sup>3</sup>

There are several national and international organizations that have published guidelines on the treatment of hypertension.<sup>11-19</sup> Thiazide-type diuretics are frequently recommended as initial therapy in patients with uncomplicated hypertension. According to the National Heart, Lung, and Blood Institute's Eighth Report of The Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 8), thiazide-type diuretics should be utilized first-line for most patients with hypertension, either alone or in combination with another antihypertensive from a different medication class (e.g., ACE inhibitors, ARBs,  $\beta$ -blockers, calcium channel blockers).<sup>11</sup> Several guidelines consistently recommend that the selection of an antihypertensive agent be based on compelling indications for use.<sup>11-19</sup> Most patients will require more than one antihypertensive medication to achieve blood pressure goals.<sup>11-19</sup> The use of a fixed-dose combination product may simplify the treatment regimen and improve adherence.<sup>13,14,17</sup> However, there are no prospective, randomized trials that have demonstrated better clinical outcomes with a fixed-dose combination product compared to the coadministration of the individual components as separate formulations.

Amiloride has been shown to be effective for the treatment of edema and hypertension, as well as for the prevention of serum potassium loss in patients taking a thiazide or loop diuretic. Clinical trials have also demonstrated comparable efficacy with the fixed-dose combination of amiloride-hydrochlorothiazide and triamterene-hydrochlorothiazide in patients with hypertension and heart failure.<sup>20-39</sup>

There is insufficient evidence to support that one brand potassium-sparing diuretic is safer or more efficacious than another. Formulations without a generic alternative should be managed through the medical justification portion of the prior authorization process.

Therefore, all brand potassium-sparing diuretics within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

## **XI. Recommendations**

No brand potassium-sparing diuretic is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

**Alabama Medicaid Agency  
Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Thiazide Diuretics  
AHFS Class 402820  
May 4, 2022**

**I. Overview**

The thiazide diuretics are approved for the treatment hypertension and edema due to renal dysfunction. They are also approved as adjunctive therapy for the management of edema associated with congestive heart failure, hepatic cirrhosis, as well as corticosteroid and estrogen therapy.<sup>1-3</sup> The thiazide diuretics inhibit the reabsorption of sodium and chloride in the cortical thick ascending limb of the loop of Henle and the early distal tubules. This action leads to an increase in the urinary excretion of sodium and chloride in approximately equivalent amounts.<sup>1-5</sup> Additionally, increased potassium and bicarbonate excretion, decreased calcium excretion, and uric acid retention may be observed. During initial thiazide therapy a reduction in cardiac output and extracellular volume occurs. However, with chronic therapy cardiac output normalizes and both peripheral vascular resistance and extracellular volume are reduced. In general, similar therapeutic and adverse effects are seen when equipotent doses are used. Thiazide diuretics are generally recommended when the glomerular filtration rate is above 30 mL/min.<sup>4-6</sup>

The thiazide diuretics that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. All of the agents are available in a generic formulation. This class was last reviewed in February 2020.

**Table 1. Thiazide Diuretics Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
Chlorothiazide	injection*, suspension	Diuril®	chlorothiazide
Hydrochlorothiazide	capsule, tablet	N/A	hydrochlorothiazide

\*Generic is available in at least one dosage form or strength.

PDL=Preferred Drug List

N/A=Not available

**II. Evidence-Based Medicine and Current Treatment Guidelines**

Current treatment guidelines that incorporate the use of the thiazide diuretics are summarized in Table 2.

**Table 2. Treatment Guidelines Using the Thiazide Diuretics**

Clinical Guideline	Recommendation(s)
American Heart Association/American College of Cardiology/Heart Failure Society of America: 2022 AHA/ACC/HFSA Guideline for the Management of Heart Failure (2022) <sup>7</sup>	<p><b>Treatment of Stage A heart failure (HF)</b></p> <ul style="list-style-type: none"> <li>Hypertension should be controlled in accordance with guideline-directed medication therapy for hypertension to prevent symptomatic HF. (LoE: A)</li> <li>In patients with type 2 diabetes and either established CVD or at high cardiovascular risk, SGLT-2 inhibitors should be used to prevent hospitalizations for HF. (LoE: A)</li> <li>In the general population, healthy lifestyle habits such as regular physical activity, maintaining normal weight, healthy dietary patterns, and avoiding smoking are helpful to reduce future risk of HF. (LoE: B)</li> <li>Patients at risk of developing HF, natriuretic peptide biomarker-based screening followed by team-based care, including a cardiovascular specialist optimizing therapy, can be useful to prevent the development of LV dysfunction (systolic or diastolic) or new-onset HF. (LoE: B)</li> </ul> <p><b>Treatment of Stage B heart failure</b></p> <ul style="list-style-type: none"> <li>In patients with LVEF≤40%, ACE inhibitors should be used to prevent HF and reduce mortality. (LoE: A)</li> <li>In patients with a recent or remote history of MI or ACS, statins should be used to</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>prevent symptomatic HF and adverse cardiovascular events. (LoE: A)</p> <ul style="list-style-type: none"> <li>• In patients with a recent MI and LVEF ≤40% who are intolerant to ACE inhibitors, ARB should be used to prevent symptomatic HF and reduce mortality. (LoE: B)</li> <li>• In patients with a recent or remote history of MI or ACS and LVEF ≤40%, evidence-based beta blockers should be used to reduce mortality. (LoE: B)</li> <li>• In patients who are at least 40 days post-MI with LVEF ≤30% and NYHA class I symptoms while receiving guideline-directed medication therapy and have reasonable expectation of meaningful survival for greater than one year, an implantable cardioverter-defibrillator is recommended for primary prevention of sudden cardiac death to reduce total mortality. (LoE: B)</li> <li>• In patients with LVEF ≤40%, beta blockers should be used to prevent symptomatic HF. (LoE: C)</li> <li>• In patients with LVEF ≤50%, thiazolidinediones should not be used because they increase the risk of HF, including hospitalizations. (LoE: B)</li> <li>• In patients with LVEF ≤50%, nondihydropyridine calcium channel blockers with negative inotropic effects may be harmful. (LoE: C)</li> </ul> <p><u>Treatment for Stage C Heart Failure with Reduced Ejection Fraction (HFrEF)</u></p> <ul style="list-style-type: none"> <li>• For patients with stage C HF, avoiding excessive sodium intake is reasonable to reduce congestive symptoms. (LoE: C)</li> <li>• In patients with HF who have fluid retention, diuretics are recommended to relieve congestion, improve symptoms, and prevent worsening HF. (LoE: B)</li> <li>• For patients with HF and congestive symptoms, addition of a thiazide (e.g., metolazone) to treatment with a loop diuretic should be reserved for patients who do not respond to moderate or high dose loop diuretics to minimize electrolyte abnormalities. (LoE: B)</li> <li>• In patients with HFrEF and NYHA class II to III symptoms, the use of an ARNI is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, the use of an ACE inhibitor is beneficial to reduce morbidity and mortality when the use of an ARNI is not feasible. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, who are intolerant to an ACE inhibitor because of cough or angioedema, and when the use of an ARNI is not feasible, the use of an ARB is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with chronic symptomatic HFrEF NYHA class II or III who tolerate an ACE inhibitor or ARB, replacement by an ARNI is recommended to further reduce morbidity and mortality. (LoE: B)</li> <li>• ARNIs should not be administered concomitantly with ACE inhibitors or within 36 hours of the last dose of an ACE inhibitor. (LoE: B)</li> <li>• ARNI or ACE inhibitors should not be administered in patients with a history of angioedema. (LoE: C)</li> <li>• In patients with HFrEF, with current or previous symptoms, use of one of the three β-blockers proven to reduce mortality (e.g., bisoprolol, carvedilol, sustained-release metoprolol succinate) is recommended to reduce mortality and hospitalizations. (LoE: A)</li> <li>• In patients with HFrEF and NYHA class II to IV symptoms, a mineralocorticoid receptor antagonist (spironolactone or eplerenone) is recommended to reduce morbidity and mortality, if eGFR is &gt;30 mL/min/1.73 m<sup>2</sup> and serum potassium is &lt;5.0 mEq/L. Careful monitoring of potassium, renal function, and diuretic dosing should be performed at initiation and closely followed thereafter to minimize risk of hyperkalemia and renal insufficiency. (LoE: A)</li> <li>• In patients taking a mineralocorticoid receptor antagonist whose serum potassium cannot be maintained at &lt;5.5 mEq/L, mineralocorticoid receptor antagonist should be discontinued to avoid life threatening hyperkalemia. (LoE: B)</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• In patients with symptomatic chronic HFrEF, SGLT-2 an inhibitor is recommended to reduce hospitalization for HF and cardiovascular mortality, irrespective of the presence of type 2 diabetes. (LoE: A)</li> <li>• The combination of hydralazine and isosorbide dinitrate is recommended to improve symptoms and reduce morbidity and mortality for patients self-identified as African Americans with NYHA class III to IV HFrEF receiving optimal therapy. (LoE: A)</li> <li>• In patients with current or previous symptomatic HFrEF who cannot be given first-line agents, such as an ARNI, ACE inhibitor or ARB because of drug intolerance or renal insufficiency, a combination of hydralazine and isosorbide dinitrate might be considered to reduce morbidity and mortality. (LoE: C)</li> <li>• In patients with HF class II to IV symptoms, omega-3 polyunsaturated fatty acid supplementation may be reasonable to use as adjunctive therapy to reduce mortality and cardiovascular hospitalizations. (LoE: B)</li> <li>• In patients with chronic HFrEF without specific indication (e.g., venous thromboembolism, atrial fibrillation, a previous thromboembolic event, or a cardioembolic source, anticoagulation is not recommended. (LoE: B)</li> <li>• Dihydropyridine and non-dihydropyridine calcium channel blockers are not recommended for patients with HFrEF. (LoE: A)</li> <li>• In patients with HFrEF, vitamins, nutritional supplements, and hormonal therapy are not recommended other than to correct specific deficiencies. (LoE: B)</li> <li>• In patients with HFrEF, class IC antiarrhythmic medication and dronedarone may increase risk of mortality. (LoE: A)</li> <li>• In patients with HFrEF, thiazolidinediones increase the risk of worsening HF symptoms and hospitalizations. (LoE: A)</li> <li>• In patients with type 2 diabetes and high cardiovascular risk, the DPP-4 inhibitors, saxagliptin and alogliptin, increase the risk of HF hospitalization and should be avoided in patients with HF. (LoE: B)</li> <li>• In patients with HFrEF, nonsteroidal anti-inflammatory drugs worsen HF symptoms and should be avoided or withdrawn whenever possible. (LoE: B)</li> <li>• For patients with symptomatic (NYHA class II to III) stable chronic HFrEF (LVEF <math>\leq</math>35%) who are receiving guideline-directed medical therapy, including a maximally tolerated dose of a beta blocker, and who are in sinus rhythm with a heart rate of <math>\geq</math>70 beats per minute at rest, ivabradine can be beneficial to reduce HF hospitalizations and cardiovascular death. (LoE: B)</li> <li>• In patients with symptomatic HFrEF despite guideline-directed medical therapy or who are unable to tolerate guideline-directed medical therapy, digoxin might be considered to decrease hospitalizations for HF. (LoE: B)</li> <li>• In select high-risk patients with HFrEF and recent worsening of HF already on guideline-directed medical therapy, an oral soluble guanylate cyclase stimulator (vericiguat) may be considered to reduce HF hospitalization and cardiovascular death. (LoE: B)</li> </ul> <p><u>Pharmacological treatment for Stage C HF with mildly reduced EF and improved EF</u></p> <ul style="list-style-type: none"> <li>• In patients with HF with mildly reduced EF, SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• Among patients with current or previous symptomatic HF with mildly reduced EF (LVEF, 41 to 49%), use of evidence-based beta blockers for HFrEF, ARNI, ACE inhibitor or ARB, and mineralocorticoid receptor antagonists may be considered to reduce the risk of HF hospitalization and cardiovascular mortality, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• In patients with HF with improved EF after treatment, guideline-directed medical therapy should be continued to prevent relapse of HF and LV dysfunction, even in patients who may become asymptomatic. (LoE: B)</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><b>Pharmacological treatment for Stage C HF with preserved EF (HFpEF)</b></p> <ul style="list-style-type: none"> <li>• Patients with hypertension and HFpEF should have medication titrated to attain blood pressure targets in accordance with published clinical practice guidelines to prevent morbidity. (LoE: C)</li> <li>• SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• In patients with HFpEF, the use of a mineralocorticoid receptor antagonist, ARB, or ARNI may be considered to decrease hospitalizations, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• Routine use of nitrates or phosphodiesterase-5 inhibitors to increase activity or quality of life in patients with HFpEF is ineffective. (LoE: B)</li> </ul> <p><b>Treatment of Stage D (advanced/refractory) HF</b></p> <ul style="list-style-type: none"> <li>• For patients with advanced HF and hyponatremia, the benefit of fluid restriction to reduce congestive symptoms is uncertain. (LoE: C)</li> <li>• Continuous intravenous inotropic support is reasonable as “bridge therapy” in patients with HF (Stage D) refractory to guideline-directed medical therapy and device therapy who are eligible for and awaiting mechanical circulatory support or cardiac transplantation. (LoE: B)</li> <li>• In select patients with HF Stage D, despite optimal guideline-directed medical therapy and device therapy who are ineligible for either mechanical circulatory support or cardiac transplantation, continuous intravenous inotropic support may be considered as palliative therapy for symptom control and improvement in functional status. (LoE: B)</li> <li>• Long-term use of either continuous or intermittent, intravenous inotropic agents, for reasons other than palliative care or as a bridge to advanced therapies, is potentially harmful. (LoE: B)</li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure (2021)</b><sup>8</sup></p>	<p><b>Pharmacological treatments indicated in patients with (NYHA Class II-IV) heart failure with reduced ejection fraction</b></p> <ul style="list-style-type: none"> <li>• An ACE inhibitor is recommended, in addition to a <math>\beta</math>-blocker, for symptomatic patients with HFrEF to reduce the risk of HF hospitalization and death.</li> <li>• A mineralocorticoid receptor antagonist (MRA) is recommended for patients with HFrEF, who remain symptomatic despite treatment with an ACE inhibitor and a <math>\beta</math>-blocker, to reduce the risk of HF hospitalization and death.</li> <li>• Dapagliflozin or empagliflozin are recommended for patients with HFrEF to reduce the risk of HF hospitalization and death. Dapagliflozin or empagliflozin are recommended, in addition to optimal medical therapy with an ACE-I/ARNI, a <math>\beta</math>-blocker and an MRA, for patients with HFrEF regardless of diabetes status.</li> <li>• Sacubitril-valsartan is recommended as a replacement for an ACE inhibitor to further reduce the risk of HF hospitalization and death in ambulatory patients with HFrEF who remain symptomatic despite optimal treatment with an ACE inhibitor, a <math>\beta</math>-blocker, and a mineralocorticoid receptor antagonist.</li> <li>• Diuretics are recommended in order to improve symptoms and exercise capacity in patients with signs and/or symptoms of congestion.</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization or cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm despite treatment with an evidence-based dose of <math>\beta</math>-blocker (or maximum tolerated dose below that), ACE inhibitor (or ARB), and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm who are unable to tolerate or have contraindications for a <math>\beta</math>-blocker. Patients should also receive an ACE inhibitor (or ARB) and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• An ARB is recommended to reduce the risk of HF hospitalization and</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>cardiovascular death in symptomatic patients unable to tolerate an ACE inhibitor (patients should also receive a <math>\beta</math>-blocker and mineralocorticoid receptor antagonist).</p> <ul style="list-style-type: none"> <li>• An ARB may be considered to reduce the risk of HF hospitalization and death in patients who are symptomatic despite treatment with a <math>\beta</math>-blocker who are unable to tolerate a mineralocorticoid receptor antagonist.</li> <li>• Vericiguat may be considered in patients in NYHA class II-IV who have had worsening HF despite treatment with an ACE-I (or ARNI), a <math>\beta</math>-blocker and an MRA to reduce the risk of CV mortality or HF hospitalization.</li> <li>• Hydralazine and isosorbide dinitrate should be considered in self-identified black patients with LVEF <math>\leq 35\%</math> or with an LVEF <math>&lt; 45\%</math> combined with a dilated LV in NYHA Class III-IV despite treatment with an ACE-I a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist to reduce the risk of HF hospitalization and death.</li> <li>• Hydralazine and isosorbide dinitrate may be considered in symptomatic patients with HFrEF who can tolerate neither an ACE inhibitor nor an ARB (or they are contraindicated) to reduce the risk of death.</li> <li>• Digoxin is a treatment with less-certain benefits and may be considered in symptomatic patients in sinus rhythm despite treatment with an ACE inhibitor (or ARB), a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist, to reduce the risk of hospitalization (both all-cause and HF-hospitalizations).</li> </ul> <p><u>Recommendations for treatment of patients with (NYHA class II-IV) heart failure with mildly reduced ejection fraction (HFmrEF)</u></p> <ul style="list-style-type: none"> <li>• Diuretics are recommended in patients with congestion and HFmrEF in order to alleviate symptoms and signs.</li> <li>• An ACE inhibitor may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An ARB may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• A <math>\beta</math>-blocker may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An MRA may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• Sacubitril/valsartan may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> </ul> <p><u>Recommendations for treatment of patients with heart failure with preserved ejection fraction (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• It is recommended to screen patients with HFpEF for both cardiovascular and noncardiovascular comorbidities, which, if present, should be treated provided safe and effective interventions exist to improve symptoms, well-being and/or prognosis.</li> <li>• Diuretics are recommended in congested patients with HFpEF in order to alleviate symptoms and signs.</li> </ul> <p><u>Recommendations for the primary prevention of heart failure in patients with risk factors for its development</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension is recommended to prevent or delay the onset of HF and prolong life.</li> <li>• Treatment with statins is recommended in patients at high risk of CV disease or with CV disease in order to prevent or delay the onset of HF, and to prevent HF hospitalizations.</li> <li>• SGLT2 inhibitors (canagliflozin, dapagliflozin, empagliflozin, ertugliflozin, sotagliflozin) are recommended in patients with diabetes at high risk of CV</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>disease or with CV disease in order to prevent HF hospitalizations.</p> <ul style="list-style-type: none"> <li>• Counselling against sedentary habit, obesity, cigarette smoking, and alcohol abuse is recommended to prevent or delay the onset of HF.</li> </ul> <p><u>Recommendations for the initial management of patients with acute heart failure – pharmacotherapy</u></p> <ul style="list-style-type: none"> <li>• Intravenous loop diuretics are recommended for all patients with acute HF admitted with signs/symptoms of fluid overload to improve symptoms. It is recommended to regularly monitor symptoms, urine output, renal function and electrolytes during use of intravenous diuretics.</li> <li>• Combination of a loop diuretic with thiazide type diuretic should be considered in patients with resistant oedema who do not respond to an increase in loop diuretic doses.</li> <li>• In patients with acute HF and SBP &gt;110 mmHg, intravenous vasodilators may be considered as initial therapy to improve symptoms and reduce congestion.</li> <li>• Inotropic agents may be considered in patients with SBP &lt;90 mmHg and evidence of hypoperfusion who do not respond to standard treatment, including fluid challenge, to improve peripheral perfusion and maintain end-organ function.</li> <li>• Inotropic agents are not recommended routinely, due to safety concerns, unless the patient has symptomatic hypotension and evidence of hypoperfusion.</li> <li>• A vasopressor, preferably norepinephrine, may be considered in patients with cardiogenic shock to increase blood pressure and vital organ perfusion.</li> <li>• Thromboembolism prophylaxis (e.g. with LMWH) is recommended in patients not already anticoagulated and with no contraindication to anticoagulation, to reduce the risk of deep venous thrombosis and pulmonary embolism.</li> <li>• Routine use of opiates is not recommended, unless in selected patients with severe/intractable pain or anxiety.</li> </ul>
<p>Eighth Joint National Committee (JNC 8): <b>2014 Evidence-based Guideline for the Management of High Blood Pressure in Adults (2014)</b><sup>9</sup></p>	<ul style="list-style-type: none"> <li>• Pharmacologic treatment should be initiated in patients ≥60 years of age to lower blood pressure at systolic blood pressure ≥150 mm Hg or diastolic blood pressure ≥90 mm Hg and to a goal systolic blood pressure &lt;150 mm Hg and goal diastolic blood pressure &lt;90 mm Hg. Adjustment of treatment is not necessary if treatment results in lower blood pressure and treatment is well tolerated and without adverse effects on health or quality of life.</li> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at diastolic blood pressure ≥90 mm Hg to a goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥150 mm Hg to a goal diastolic blood pressure &lt;140 mm Hg.</li> <li>• For patients ≥18 years of age with chronic kidney disease or diabetes, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥140 mm Hg or diastolic blood pressure ≥90 mm Hg and to a goal systolic blood pressure &lt;140 mm Hg and goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• Initial antihypertensive treatment for the general nonblack population, including those with diabetes, should include thiazide-type diuretic, calcium channel blocker (CCB), ACE inhibitor, or ARB.</li> <li>• Initial antihypertensive treatment for the general black population, including those with diabetes, should include thiazide-type diuretic or CCB.</li> <li>• For patients ≥18 years of age with chronic kidney disease regardless of race or diabetes status, initial (or add-on) treatment should include an ACE inhibitor or ARB to improve kidney outcomes.</li> <li>• The main goal of antihypertensive treatment is to attain and maintain goal blood pressure.</li> <li>• If goal blood pressure is not attained within a month of treatment, the dose of the</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>initial drug should be increased or second drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</p> <ul style="list-style-type: none"> <li>• If goal is not achieved with two drugs, a third drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• An ACE inhibitor and ARB should not be used together.</li> <li>• Antihypertensive classes can be used if the patient is unable to achieve goal blood pressure with three agents or had a contraindication to a preferred class.</li> <li>• If blood pressure is not able to be achieved or in complicated patients, referral to a hypertension specialist may be indicated.</li> </ul>
<p>International Society of Hypertension: Global Hypertension Practice Guidelines (2020)<sup>10</sup></p>	<p><b>Lifestyle modifications</b></p> <ul style="list-style-type: none"> <li>• Lifestyle modification is the first line of antihypertensive treatment.</li> <li>• Salt reduction: Reduce salt added when preparing foods, and at the table. Avoid or limit consumption of high salt foods such as soy sauce, fast foods and processed food including breads and cereals high in salt.</li> <li>• Healthy diet: Eating a diet that is rich in whole grains, fruits, vegetables, polyunsaturated fats and dairy products and reducing food high in sugar, saturated fat and trans fats, such as the DASH diet.</li> <li>• Healthy drinks: Moderate consumption of coffee, green and black tea. Other beverages that can be beneficial include karkadé (hibiscus) tea, pomegranate juice, beetroot juice and cocoa.</li> <li>• Moderation of alcohol consumption: The recommended daily limit for alcohol consumptions is 2 standard drinks for men and 1.5 for women (10 g alcohol/standard drink). Avoid binge drinking.</li> <li>• Weight reduction: Body weight control is indicated to avoid obesity. Particularly abdominal obesity should be managed. Ethnic-specific cut-offs for BMI and waist circumference should be used. Alternatively, a waist-to-height ratio &lt;0.5 is recommended for all populations.</li> <li>• Smoking cessation: Smoking is a major risk factor for cardiovascular disease (CVD), COPD and cancer. Smoking cessation and referral to smoking cessation programs are advised.</li> <li>• Regular physical activity: Studies suggest that regular aerobic and resistance exercise may be beneficial for both the prevention and treatment of hypertension. Moderate intensity aerobic exercise (walking, jogging, cycling, yoga, or swimming) for 30 minutes on five to seven days per week Strength training also can help reduce blood pressure. Performance of resistance/strength exercises on two to three days per week.</li> <li>• Reduce stress and induce mindfulness: Stress should be reduced and mindfulness or meditation introduced into the daily routine.</li> <li>• Reduce exposure to air pollution and cold temperature: Evidence from studies support a negative effect of air pollution on blood pressure in the long-term.</li> </ul> <p><b>Pharmacological Treatment</b></p> <ul style="list-style-type: none"> <li>• Ideal characteristics of drug treatment <ul style="list-style-type: none"> <li>○ Treatments should be evidence-based in relation to morbidity/mortality prevention.</li> <li>○ Use a once-daily regimen which provides 24-hour blood pressure control.</li> <li>○ Treatment should be affordable and/or cost-effective relative to other agents.</li> <li>○ Treatments should be well-tolerated.</li> <li>○ Evidence of benefits of use of the medication in populations to which it is to be applied.</li> </ul> </li> <li>• General scheme for drug treatment <ul style="list-style-type: none"> <li>○ Lifestyle modification is the first line of antihypertensive treatment.</li> <li>○ Grade 1 hypertension (BP 140 to 159/ 90 to 99): Immediate drug treatment in high-risk patients or those with CVD, chronic kidney disease</li> </ul> </li> </ul>

Clinical Guideline	Recommendation(s)
	<p>(CKD), diabetes mellitus (DM), or hypertension-mediated organ damage (HMOD). Drug treatment after three to six months of lifestyle intervention if BP still not controlled in low to moderate risk patients.</p> <ul style="list-style-type: none"> <li>○ Grade 2 hypertension (BP <math>\geq</math>160/100): Immediate drug treatment in all patients.</li> <li>● Core drug-treatment strategy <ul style="list-style-type: none"> <li>○ Step 1: Dual low-dose combination (ACE inhibitor or ARB plus dihydropyridine-calcium channel blockers (DHP-CCB)); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance; consider ACE/ARB plus DHP-CCB or DHP-CCB plus thiazide-like diuretics in black patients.</li> <li>○ Step 2: Dual full-dose combination (ACE inhibitor or ARB plus DHP-CCB); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance.</li> <li>○ Step 3: Triple combination (ACE/ARB plus DHP-CCB plus thiazide-like diuretic).</li> <li>○ Step 4, resistant hypertension: triple combination plus spironolactone or other drug, alternatives include amiloride, doxazosin, eplerenone, clonidine, or <math>\beta</math>-blocker. Caution with spironolactone or other potassium sparing diuretics when estimated GFR <math>&lt;</math>45 mL/min/1.73m<sup>2</sup> or K<sup>+</sup> <math>&gt;</math>4.5 mmol/L.</li> <li>○ Consider <math>\beta</math>-blockers at any treatment step when there is a specific indications for their use, e.g., heart failure, angina, post-MI, atrial fibrillation, or younger women planning pregnancy or pregnant.</li> </ul> </li> </ul>
<p>Hypertension Canada: <b>2020 Guidelines for the Prevention, Diagnosis, Risk Assessment, and Treatment of Hypertension in Adults and Children (2020)</b><sup>11</sup></p>	<p><u>Indications for drug therapy for adults with hypertension without compelling indications for specific agents</u></p> <ul style="list-style-type: none"> <li>● Antihypertensive therapy should be prescribed for average diastolic blood pressure (DBP) measurements of <math>\geq</math>100 mmHg or average systolic blood pressure (SBP) measurements of <math>\geq</math>160 mmHg in patients without macrovascular target organ damage or other cardiovascular risk factors.</li> <li>● Antihypertensive therapy should be strongly considered for average DPB readings <math>\geq</math>90 mmHg or for average SBP readings <math>\geq</math>140 mmHg in the presence of macrovascular target organ damage or other independent cardiovascular risk factors.</li> <li>● For high-risk patients, aged 50 years or older, with SBP levels <math>\geq</math>130 mmHg, intensive management to target a SBP <math>&lt;</math>120 mmHg should be considered. Patient selection for intensive management is recommended and caution should be taken in certain high-risk groups.</li> </ul> <p><u>Indications for drug therapy for adults with diastolic and with or without systolic hypertension</u></p> <ul style="list-style-type: none"> <li>● Initial therapy should be with either monotherapy or single pill combination (SPC). <ul style="list-style-type: none"> <li>○ Recommended monotherapy choices are: <ul style="list-style-type: none"> <li>▪ A thiazide/thiazide-like diuretic, with longer-acting diuretics preferred;</li> <li>▪ A <math>\beta</math>-blocker (in patients <math>&lt;</math>60 years of age);</li> <li>▪ An angiotensin-converting enzyme (ACE) inhibitor (in nonblack patients);</li> <li>▪ An angiotensin receptor blocker (ARB); or</li> <li>▪ A long-acting calcium channel blocker (CCB).</li> </ul> </li> <li>○ Recommended SPC choices are those in which an ACE inhibitor is combined with a CCB, ARB with a CCB, or ACE inhibitor or ARB with a diuretic.</li> </ul> </li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>○ Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line choices. Useful choices include a thiazide/thiazide-like diuretic or CCB with either: ACE inhibitor, ARB, or <math>\beta</math>-blocker. Caution should be exercised in combining a nondihydropyridine CCB and a <math>\beta</math>-blocker. The combination of an ACE inhibitor and an ARB is not recommended.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other antihypertensive drugs may be added.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated hypertension; <math>\beta</math>-blockers are not recommended as first-line therapy for uncomplicated hypertension in patients <math>\geq 60</math> years of age; and ACE inhibitors are not recommended as first-line therapy for uncomplicated hypertension in black patients. However, these agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Indications for drug therapy for adults with isolated systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be single-agent therapy with a thiazide/thiazide-like diuretic, a long-acting dihydropyridine CCB, or an ARB. If there are adverse effects, another drug from this group should be substituted. Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line options.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other classes of drugs (such as <math>\alpha</math>-blockers, ACE inhibitors, centrally acting agents, or nondihydropyridine CCBs) may be combined or substituted.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated isolated systolic hypertension; and <math>\beta</math>-blockers are not recommended as first-line therapy for isolated systolic hypertension in patients <math>\geq 60</math> years of age. However, both agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Guidelines for hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• For most hypertensive patients with CAD, an ACE inhibitor or ARB is recommended.</li> <li>• For hypertensive patients with CAD, but without coexisting systolic heart failure, the combination of an ACE inhibitor and ARB is not recommended.</li> <li>• For high-risk hypertensive patients, when combination therapy is being used, choices should be individualized. The combination of an ACE inhibitor and a dihydropyridine CCB is preferable to an ACE inhibitor and a thiazide/thiazide-like diuretic in selected patients.</li> <li>• For patients with stable angina pectoris but without previous heart failure, myocardial infarction, or coronary artery bypass surgery, either a <math>\beta</math>-blocker or CCB can be used as initial therapy.</li> <li>• Short-acting nifedipine should not be used.</li> <li>• When decreasing SBP to target levels in patients with established CAD (especially if isolated systolic hypertension is present), be cautious when the DBP is <math>\leq 60</math> mmHg because of concerns that myocardial ischemia might be exacerbated, especially in patients with left ventricular hypertrophy (LVH).</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><b>Guidelines for patients with hypertension who have had a recent myocardial infarction</b></p> <ul style="list-style-type: none"> <li>• Initial therapy should include a <math>\beta</math>-blocker as well as an ACE inhibitor.</li> <li>• An ARB can be used if the patient is intolerant of an ACE inhibitor.</li> <li>• CCBs may be used in patients after myocardial infarction when <math>\beta</math>-blockers are contraindicated or not effective. Nondihydropyridine CCBs should not be used when there is heart failure, evidenced by pulmonary congestion on examination or radiography.</li> </ul> <p><b>Treatment of hypertension in association with heart failure</b></p> <ul style="list-style-type: none"> <li>• In patients with systolic dysfunction (ejection fraction &lt;40%), ACE inhibitors and <math>\beta</math>-blockers are recommended for initial therapy. Aldosterone antagonists (mineralocorticoid receptor antagonists) may be combined in treatment for patients with a recent cardiovascular hospitalization, acute myocardial infarction, elevated B-type natriuretic peptide or N-terminal pro-B-type natriuretic peptide level, or New York Heart Association (NYHA) Class II-IV symptoms. Careful monitoring for hyperkalemia is recommended when combining an aldosterone antagonist with ACE inhibitor or ARB treatment. Other diuretics are recommended as additional therapy if needed. Beyond considerations of BP control, doses of ACE inhibitors or ARBs should be titrated to those reported to be effective in trials unless adverse effects become manifest.</li> <li>• An ARB is recommended if ACE inhibitors are not tolerated.</li> <li>• A combination of hydralazine and isosorbide dinitrate is recommended if ACE inhibitors and ARBs are contraindicated or not tolerated.</li> <li>• For hypertensive patients whose BP is not controlled, an ARB may be combined with an ACE inhibitor and other antihypertensive drug treatment. Careful monitoring should be used if combining an ACE inhibitor and an ARB because of potential adverse effects such as hypotension, hyperkalemia, and worsening renal function. Additional therapies may also include dihydropyridine CCBs.</li> <li>• An angiotensin receptor-neprilysin inhibitor (ARNI) should be used in place of an ACE inhibitor or ARB for patients with HFrEF (&lt;40%) who remain symptomatic despite treatment with appropriate dose of guideline directed HF therapy. Eligible patients must have a serum potassium &lt;5.2 mmol/L, an eGFR <math>\leq</math>30 mL/min/1.73m<sup>2</sup> and close surveillance of serum potassium and creatinine.</li> </ul> <p><b>Treatment of hypertension in association with stroke</b></p> <ul style="list-style-type: none"> <li>• BP management in acute ischemic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> <li>• BP management after acute ischemic stroke <ul style="list-style-type: none"> <li>○ Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack.</li> <li>○ After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently &lt;140/90 mmHg.</li> <li>○ Treatment with an ACE inhibitor and thiazide/thiazide-like diuretic combination is preferred.</li> <li>○ For patients with stroke, the combination of an ACE inhibitor and ARB is not recommended.</li> </ul> </li> <li>• BP management in hemorrhagic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> </ul> <p><b>Treatment of hypertension in association with LVH</b></p> <ul style="list-style-type: none"> <li>• Hypertensive patients with LVH should be treated with antihypertensive therapy to decrease the rate of subsequent cardiovascular events.</li> <li>• The choice of initial therapy can be influenced by the presence of LVH. Initial therapy can be drug treatment using ACE inhibitors, ARBs, long-acting CCBs, or thiazide/thiazide-like diuretics. Direct arterial vasodilators such as hydralazine or</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><b>minoxidil should not be used.</b></p> <p><b>Treatment of hypertension in association with nondiabetic chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>• Individualize BP targets in patients with chronic kidney disease. Consider intensive targets (SBP &lt;120 mmHg) in appropriate patients.</li> <li>• For patients with hypertension and proteinuric chronic kidney disease (urinary protein &gt;150 mg per 24 hours or albumin to creatinine ratio &gt;30 mg/mmol), initial therapy should be an ACE inhibitor or an ARB if there is intolerance to ACE inhibitors.</li> <li>• In most cases, combination therapy with other antihypertensive agents might be needed to reach target BP levels.</li> <li>• The combination of an ACE inhibitor and ARB is not recommended for patients with nonproteinuric chronic kidney disease.</li> </ul> <p><b>Treatment of hypertension in association with renovascular disease</b></p> <ul style="list-style-type: none"> <li>• Patients with hypertension attributable to atherosclerotic renal artery stenosis should be primarily medically managed because renal angioplasty and stenting offers no benefit over optimal medical therapy alone.</li> <li>• Renal artery angioplasty and stenting for atherosclerotic hemodynamically significant renal artery stenosis could be considered for patients with uncontrolled hypertension resistant to maximally tolerated pharmacotherapy, progressive renal function loss, and acute pulmonary edema.</li> <li>• Patients with confirmed renal fibromuscular dysplasia (FMD) should be referred to a hypertension specialist.</li> <li>• Renal artery angioplasty without stenting is recommended for treatment of FMD-related renal artery stenosis. Stenting is not recommended unless needed because of a periprocedural dissection. Surgical revascularization should be considered in cases of complex lesions less amendable to angioplasty, stenosis associated with complex aneurysm, and restenosis despite two unsuccessful attempts of angioplasty.</li> </ul> <p><b>Treatment of hypertension in association with diabetes mellitus</b></p> <ul style="list-style-type: none"> <li>• Persons with diabetes mellitus should be treated to attain SBP of &lt;130 mmHg and DBP of &lt;80 mmHg.</li> <li>• For persons with cardiovascular or kidney disease, including microalbuminuria, or with cardiovascular risk factors in addition to diabetes and hypertension, an ACE inhibitor or an ARB is recommended as initial therapy.</li> <li>• For persons with diabetes and hypertension not included in other guidelines in this section, appropriate choices include (in alphabetical order): ACE inhibitors, ARBs, dihydropyridine CCBs, and thiazide/thiazide-like diuretics.</li> <li>• If target BP levels are not achieved with standard-dose monotherapy, additional antihypertensive therapy should be used. For persons in whom combination therapy with an ACE inhibitor is being considered, a dihydropyridine CCB is preferable to a thiazide/thiazide-like diuretic.</li> </ul> <p><b>Resistant hypertension</b></p> <ul style="list-style-type: none"> <li>• Resistant hypertension is defined as BP above target despite three or more BP-lowering drugs at optimal doses preferably including a diuretic (and usually a renin-angiotensin-aldosterone system blocker and a CCB).</li> <li>• Accurate office and out-of-office BP measurement is essential.</li> <li>• Other reasons for apparent resistant hypertension should be eliminated before diagnosing true resistant hypertension, including nonadherence, white coat effect, and secondary hypertension.</li> <li>• Pharmacotherapy with the additional use of spironolactone, bisoprolol, doxazosin, amiloride, eplerenone, or clonidine with the baseline regimen decreases BP</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>significantly, with the greatest BP-lowering shown with spironolactone.</p> <ul style="list-style-type: none"> <li>• Patients with resistant hypertension should be referred to providers with expertise in diagnosis and management of hypertension.</li> </ul> <p><u>Hypertension and pediatrics</u></p> <ul style="list-style-type: none"> <li>• BP should be measured regularly in children three years of age or older; the auscultatory method is the gold-standard at present.</li> <li>• Initial therapy should be monotherapy, with an ACE inhibitor or ARB (not first-line in black children), or a long-acting dihydropyridine CCB.</li> <li>• The treatment goal is systolic and diastolic office BP and/or ABPM &lt; 95th percentile or &lt;90<sup>th</sup> percentile in children with risk factors or target organ damage.</li> <li>• Complex cases should be referred to an expert in pediatric hypertension.</li> </ul> <p><u>Hypertension and pregnancy</u></p> <ul style="list-style-type: none"> <li>• Up to 7% of pregnancies are complicated by a hypertensive disorder of pregnancy, and approximately 5% of women will have chronic hypertension when they become pregnant.</li> <li>• The prevalence of hypertension in pregnancy is expected to increase with women becoming pregnant later in their reproductive years and the increasing prevalence of cardiovascular comorbidities such as increased preconception body mass index and maternal diabetes.</li> <li>• The possibility of pregnancy should be considered when managing women with hypertension who are of reproductive age.</li> <li>• Preconception counselling should be offered to all women with hypertension who are considering pregnancy.</li> <li>• ACE inhibitor and ARB therapy should be avoided before conception and during pregnancy unless there is a compelling indication for their use (i.e., proteinuric kidney disease).</li> <li>• Hypertension during pregnancy can increase the risk of adverse maternal and fetal outcomes, including an increased risk of preeclampsia, placental abruption, prematurity, small for gestational age infants, stillbirth, and maternal renal and retinal injury, thus generally requires involvement of an interdisciplinary team including obstetrical care providers.</li> <li>• Antihypertensive therapy is recommended for average SBP measurements of <math>\geq 140</math> mmHg or DBP measurements of <math>\geq 90</math> mmHg in pregnant women with chronic hypertension, gestational hypertension, or preeclampsia. Initial antihypertensive therapy should be monotherapy from the following first-line drugs: oral labetalol, oral methyldopa, long-acting oral nifedipine, or other oral <math>\beta</math>-blockers (acebutolol, metoprolol, pindolol, and propranolol). Other antihypertensive drugs can be considered as second-line drugs including: clonidine, hydralazine, and thiazide diuretics.</li> <li>• Women with severe hypertension with SBP <math>\geq 160</math> mmHg or DBP <math>\geq 110</math> mmHg in pregnancy or postpartum require urgent antihypertensive therapy because it is considered an obstetrical emergency.</li> <li>• Antihypertensive drugs used in breastfeeding women include: labetalol, methyldopa, long-acting nifedipine, enalapril, or captopril.</li> </ul>
<p>European Society of Hypertension/ European Society of Cardiology: <b>2018 Guidelines for the management of arterial hypertension (2018)</b><sup>12</sup></p>	<p><u>Treatment strategies and choice of antihypertensive drugs</u></p> <ul style="list-style-type: none"> <li>• Diuretics (including thiazides, chlorthalidone, and indapamide), <math>\beta</math>-blockers, calcium channel blocker (CCB), angiotensin-converting enzyme (ACE) inhibitors, and angiotensin receptor blockers (ARBs) are all suitable for the initiation and maintenance of antihypertensive treatment, either as monotherapy or in some combinations.</li> <li>• Some agents should be considered as the preferential choice in specific conditions because used in trials in those conditions or because of greater effectiveness in specific types of organ damage. Preferred combinations should comprise a renin-</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>angiotensin system (RAS) blocker (either an ACE inhibitor or an ARB) with a CCB or diuretic.</p> <ul style="list-style-type: none"> <li>• It is recommended that beta-blockers are combined with any of the other major drug classes when there are specific clinical situations, e.g. angina, post-myocardial infarction, heart failure, or heart rate control.</li> <li>• Initiation of antihypertensive therapy with a two-drug combination may be considered in patients with markedly high baseline blood pressure (BP) or at high cardiovascular (CV) risk.</li> <li>• The combination of two antagonists of the RAS is not recommended and should be discouraged.</li> <li>• Other drug combinations should be considered and probably are beneficial in proportion to the extent of BP reduction. However, combinations that have been successfully used in trials may be preferable.</li> <li>• Combinations of two antihypertensive drugs at fixed doses in a single tablet may be recommended and favored, because reducing the number of daily pills improves adherence, which is low in patients with hypertension. Exceptions are frail older patients and those at low risk and with grade one hypertension (particularly if systolic BP is &lt;150 mmHg).</li> <li>• It is recommended that if BP is not controlled with a three-drug combination, treatment should be increased by the addition of spironolactone or, if not tolerated, other diuretics such as amiloride or higher doses of other diuretics, a beta-blocker, or an alpha-blocker.</li> </ul> <p><u>Treatment strategies in white-coat and masked hypertension</u></p> <ul style="list-style-type: none"> <li>• In white-coat hypertensives without additional risk factors, therapeutic intervention may be limited to lifestyle changes only, but this decision should be accompanied by close follow-up.</li> <li>• In white-coat hypertensives with a higher CV risk or hypertension-mediated organ damage, drug treatment may be considered in addition to lifestyle changes.</li> <li>• In masked hypertension, both lifestyle measures and antihypertensive drug treatment should be considered, because this type of hypertension has been consistently found to have a CV risk very close to that of in- and out-of-office hypertension.</li> <li>• Antihypertensive drug up-titration should be considered in treated patients whose out-of-office BP is not controlled (i.e., masked uncontrolled hypertension), because of the high CV risk of these patients.</li> </ul> <p><u>Antihypertensive treatment strategies in the elderly</u></p> <ul style="list-style-type: none"> <li>• It is recommended that older patients (≥65 years) are treated with the same recommendations in non-older patient population. In very old patients (≥80 years), it may be appropriate to initiate treatment with monotherapy.</li> <li>• In all older patients, when combination therapy is used, it is recommended that this is initiated at the lowest available doses. In all older patients, and especially very old or frail patients, the possible occurrence of postural BP should be closely monitored and symptoms of possible hypotensive episodes checked by ambulatory blood pressure monitoring.</li> <li>• Unless required for concomitant diseases, loop diuretics and alpha-blockers should be avoided because of their association with injurious falls.</li> <li>• Renal function should be frequently assessed to detect possible increases in serum creatinine and reductions in estimated glomerular filtration rate (eGFR) as a result of BP-related reductions in renal perfusion.</li> <li>• When treated, BP should be lowered to a systolic value of 130 to 139 mmHg and a diastolic value of &lt;80 mmHg if tolerated. Treated values of &lt;130 mmHg should be avoided.</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><u>Treatment strategies in hypertensive women</u></p> <ul style="list-style-type: none"> <li>• Hormone therapy and selective estrogen receptor modulators are not recommended and should not be used for primary or secondary prevention of CVD.</li> <li>• In women with gestational hypertension, pre-existing hypertension superimposed by gestational hypertension, or with hypertension and subclinical organ damage or symptoms, initiation of drug treatments is recommended when SBP is <math>\geq 140</math> mmHg or DBP <math>\geq 90</math> mmHg. In all other cases, initiation of drug treatment is recommended when SBP is <math>\geq 150</math> mmHg or DBP is <math>\geq 95</math> mmHg.</li> <li>• Methyldopa, labetalol, and CCBs are recommended as the drugs of choice for the treatment of hypertension in pregnancy.</li> <li>• ACE inhibitors, ARBs, or direct renin inhibitors are not recommended during pregnancy.</li> <li>• SBP <math>\geq 170</math> mmHg or DBP <math>\geq 110</math> mmHg in a pregnant woman is an emergency, and admission to hospital is recommended.</li> <li>• In severe hypertension, drug treatment with intravenous (IV) labetalol, oral methyldopa, or nifedipine is recommended.</li> <li>• The recommended treatment for hypertensive crisis is IV labetalol or nicardipine and magnesium.</li> <li>• In pre-eclampsia associated with pulmonary edema, nitroglycerin given as an IV infusion is recommended.</li> <li>• In women with gestational hypertension or mild-pre-eclampsia, delivery is recommended at 37 weeks.</li> <li>• It is recommended to expedite delivery in pre-eclampsia with adverse conditions, such as visual disturbances or hemostatic disorders</li> <li>• In women at high risk of pre-eclampsia, provided they are at low risk of gastrointestinal hemorrhage, treatment with low dose aspirin from 12 weeks until delivery may be considered.</li> <li>• Methyldopa, labetalol, and nifedipine should be considered preferential antihypertensive drugs in pregnancy. Intravenous labetalol or infusion of nitroprusside should be considered in case of emergency (pre-eclampsia).</li> </ul> <p><u>Treatment strategies in patients with diabetes</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive drug treatment is recommended for people with diabetes when office BP is <math>\geq 140/90</math> mmHg.</li> <li>• A SBP goal <math>&lt; 130</math> mmHg is recommended in patients with diabetes and <math>&lt; 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg.</li> <li>• In older people, the target SBP range is 130 to 139 mmHg.</li> <li>• The DBP target in patients with diabetes is recommended to be <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• It is recommended to initiate treatment with a combination of a RAS blocker with a CCB or thiazide/thiazide-like diuretic.</li> <li>• It is recommended that individual drug choice takes comorbidities into account.</li> <li>• Simultaneous administration of two blockers of the RAS is not recommended and should be avoided in patients with diabetes.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with nephropathy</u></p> <ul style="list-style-type: none"> <li>• In patients with diabetic and non-diabetic CKD, it is recommended that an office BP of <math>\geq 140/90</math> mmHg be treated with lifestyle advice and BP-lowering medication.</li> <li>• In patients with diabetic or non-diabetic CKD, it is recommended to lower SBP to a range of 130 to 139 mmHg. And individualized treatments should be considered according to its tolerability and impact on renal function and electrolytes.</li> <li>• A combination of a RAS blocker with a CCB or a diuretic is recommended as initial therapy.</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• RAS blockers are more effective in reducing albuminuria than other antihypertensive agents, and are indicated in hypertensive patients in the presence of microalbuminuria or overt proteinuria.</li> <li>• Combination of two RAS blockers, though potentially more effective in reducing proteinuria, is not recommended.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with cerebrovascular disease</u></p> <ul style="list-style-type: none"> <li>• In patients with acute intracerebral hemorrhage, immediate BP lowering is not recommended for patients with SBP &lt;220 mmHg. In patients with SBP <math>\geq</math>220 mmHg, care acute BP lowering with IV therapy to &lt;180 mmHg should be considered.</li> <li>• In acute ischemic stroke, routine BP lowering with antihypertensive therapy is not recommended with the exceptions with the exceptions: in patients with acute ischemic stroke who are eligible for IV thrombolysis, BP should be carefully lowered and maintained at &lt;180/105 mmHg for at least the first 24 hours after thrombolysis; In patients with markedly elevated BP who do not receive fibrinolysis, drug therapy may be considered, based on clinical judgement, to reduce BP by 15% during the first 24 hours after the stroke onset.</li> <li>• In hypertensive patients with an acute cerebrovascular event, antihypertensive treatment is recommended immediately for transient ischemic attack (TIA) and after several days in ischemic stroke.</li> <li>• In all hypertensive patients with ischemic stroke or TIA, an SBP target range of 120 to 130 mmHg should be considered.</li> <li>• The recommended antihypertensive drug treatment strategy for stroke prevention is a RAS blocker plus a CCB or a thiazide-like diuretic.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with heart failure (HF) or left ventricular hypertrophy (LVH)</u></p> <ul style="list-style-type: none"> <li>• In hypertensive patients with heart failure (with reduced or preserved ejection fraction), BP-lowering treatment should be considered if <math>\geq</math>140/90 mmHg.</li> <li>• In patients with HFrEF, it is recommended that BP-lowering treatment comprises an ACE inhibitor or ARB, and a beta-blocker and a diuretic and/or mineralocorticoid receptor antagonist (MRA) if required.</li> <li>• Dihydropyridine CCBs may be added if BP control is not achieved.</li> <li>• In patients with HFpEF, BP treatment threshold and target values should be the same as for HFrEF).</li> <li>• Because no specific drug has proven its superiority, all major agents can be used.</li> <li>• In all patients with LVH, it is recommended to treat with a RAS blocker or in combination with a CCB or diuretic and SBP should be lowered to a range of 120 to 130 mmHg.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• In patients with CAD receiving BP-lowering drugs, it is recommended to target SBP to <math>\leq</math>130 mmHg if tolerated, but not &lt;120 mmHg. In older patients, the target is an SBP range of 130 to 140 mmHg. The target DBP is &lt;80 mmHg, but not &lt;70 mmHg.</li> <li>• In hypertensive patients with a history of myocardial infarction, beta-blockers and RAS blockers are recommended as part of treatment.</li> <li>• In patients with asymptomatic angina, beta-blockers and/or CCBs are recommended.</li> </ul>
<p>National Institute for Health and Clinical Excellence: <b>Hypertension in adults: diagnosis</b></p>	<p><u>Choosing antihypertensive drug treatment (for people with or without type II diabetes)</u></p> <ul style="list-style-type: none"> <li>• Where possible, recommend treatment with drugs taken only once a day.</li> <li>• Prescribe non-proprietary drugs where these are appropriate and minimize cost.</li> <li>• Offer people with isolated systolic hypertension (systolic blood pressure <math>\geq</math>160 mmHg) the same treatment as people with both raised systolic and diastolic blood</li> </ul>

Clinical Guideline	Recommendation(s)
<p><b>and management (2019)<sup>13</sup></b></p>	<p>pressure.</p> <ul style="list-style-type: none"> <li>• Offer antihypertensive drug treatment to women of child-bearing potential with diagnosed hypertension in line with recommendations in this guideline. For women considering pregnancy or who are pregnant or breastfeeding, manage hypertension in line with the recommendations on Management of pregnancy with chronic hypertension and Breastfeeding in 'Hypertension in pregnancy'.</li> <li>• When choosing antihypertensive drug treatment for adults of black African or African-Caribbean family origin, consider an angiotensin II receptor blocker, in preference to an angiotensin-converting enzyme inhibitor.</li> </ul> <p><u>Step one treatment</u></p> <ul style="list-style-type: none"> <li>• Patients &lt;55 years of age should be offered a step one antihypertensive with an angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB).</li> <li>• Offer an ACE inhibitor or an ARB to adults starting step 1 antihypertensive treatment who have type II diabetes and are of any age or family origin or those aged &lt;55 years but not of black African or African-Caribbean family origin.</li> <li>• If an ACE inhibitor is not tolerated, offer an ARB.</li> <li>• Do not combine an ACE inhibitor with an ARB for the treatment of hypertension.</li> <li>• Offer a calcium channel blocker (CCB) to adults starting step 1 antihypertensive treatment who are &gt;55 years of age and do not have diabetes and are of black African or African-Caribbean family origin and do not have type II diabetes and of any age.</li> <li>• If a CCB is not suitable, for example because of edema or intolerance, or if there is evidence of heart failure or a high risk of heart failure, offer a thiazide-like diuretic.</li> <li>• If diuretic treatment is to be initiated or changed, offer a thiazide-like diuretic, such as indapamide in preference to a conventional thiazide diuretic such as bendroflumethiazide or hydrochlorothiazide.</li> <li>• For adults with hypertension who are already receiving treatment with bendroflumethiazide or hydrochlorothiazide, who have stable, well-controlled blood pressure, continue with their treatment.</li> </ul> <p><u>Step two treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering next step treatment for hypertension discuss with the person if they are taking their medicine as prescribed and support adherence in line with NICE's guideline on "Medicines adherence: involving patients decisions about prescribed medicines and supporting adherence".</li> <li>• If hypertension is not controlled with a step one treatment of an ACE inhibitor or ARB, offer choice of one of the following drugs in addition to the step one treatment: a CCB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults taking step one treatment of a CCB, offer the choice of one of the following drugs in addition to the step one treatment: an ACE inhibitor or an ARB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults of black African or African-Caribbean family origin who do not have type 2 diabetes taking step one treatment, consider an ARB, in preference to an ACE inhibitor, in addition to step one treatment.</li> </ul> <p><u>Step three treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering step three treatment, review the person's medications to ensure they are being taken at the optimal doses and discuss adherence (see recommendation under step two).</li> <li>• If hypertension is not controlled in adults taking step two treatment, offer a combination of an ACE inhibitor or ARB and a CCB and a thiazide-like diuretic.</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><u>Step four treatment</u></p> <ul style="list-style-type: none"> <li>• If hypertension is not controlled in adults taking the optimal tolerated doses of an ACE inhibitor or an ARB plus a CCB and a thiazide-like diuretic, regard them as having resistant hypertension.</li> <li>• Before considering further treatment for a person with resistant hypertension, confirm elevated clinic blood pressure measurements using ambulatory or home blood pressure recordings, assess for postural hypotension, and discuss adherence.</li> <li>• For people with confirmed resistant hypertension, consider adding a fourth antihypertensive drug as step four treatment or seeking specialist advice.</li> <li>• Consider further diuretic therapy with low-dose spironolactone for adults with resistant hypertension starting step four treatment who have a blood potassium level of 4.5 mmol/l or less. Use particular caution in people with a reduced estimated glomerular filtration rate because they have an increased risk of hyperkalemia.</li> <li>• When using further diuretic therapy for step four treatment of resistant hypertension, monitor blood sodium and potassium and renal function within one month of starting treatment and repeat as needed thereafter.</li> <li>• Consider an alpha-blocker or beta-blocker for adults with resistant hypertension starting step four treatment who have a blood potassium level of more than 4.5 mmol/l.</li> <li>• If blood pressure remains uncontrolled in people with resistant hypertension taking the optimal tolerated doses of four drugs, seek specialist advice.</li> </ul>
<p>International Society on Hypertension in Blacks: <b>Management of High Blood Pressure in Blacks (2010)</b><sup>14</sup></p>	<ul style="list-style-type: none"> <li>• To attain and maintain blood pressure (BP) below target levels, multiple antihypertensive drugs will be required in most hypertensive blacks.</li> <li>• Use of two-drug combination therapy when SBP is &gt;15 mm Hg and/or DBP is &gt;10 mm Hg above goal levels is increasingly recommended as first-line therapy.</li> <li>• Two-drug regimens have generally contained a thiazide-type diuretic; however, the combination of a calcium channel blocker (CCB) with either an ACE inhibitor or an ARB has been shown equally efficacious in BP lowering but with demonstrated superiority (CCB+ACE) for hard clinical outcomes compared with the same ACE inhibitor plus a thiazide-type diuretic.</li> <li>• In secondary prevention patients, the combination therapy should include a drug(s) with the appropriate compelling indications.</li> <li>• Certain classes of antihypertensive medications, specifically diuretics and CCBs, lower BP on average more than <math>\beta</math>-blockers and renin-angiotensin system (RAS) blockers in black patients when used as monotherapies.</li> <li>• In the absence of compelling indications, when BP is near goal levels, monotherapy with a diuretic or a CCB is preferred.</li> <li>• Lifestyle modifications should be initiated in all patients with hypertension, whether or not pharmacotherapy is planned.</li> <li>• ACE inhibitors or ARBs are recommended as alternative monotherapy options in the treatment of hypertension in blacks. The rationale for their lower tier monotherapy recommendation is because they have consistently achieved lesser average reductions in BP relative to that observed with monotherapy using either a diuretic or CCB.</li> </ul>
<p>Kidney Disease Improving Clinical Outcomes Group; <b>KDIGO Clinical Practice Guideline for the Management of Blood Pressure in Chronic Kidney Disease</b></p>	<p><u>Blood pressure measurement</u></p> <ul style="list-style-type: none"> <li>• The Work Group recommends standardized office blood pressure (BP) measurement in preference to routine office BP measurements for the management of high BP in adults.</li> <li>• The Work Group suggests that out-of-office BP measurements with ambulatory BP monitoring (ABPM) or home BP monitoring (HBPM) be used to complement standardized office BP readings for the management of high BP.</li> </ul> <p><u>Lifestyle interventions for lowering BP in patients with chronic kidney disease (CKD)</u></p>

Clinical Guideline	Recommendation(s)
(2021) <sup>15</sup>	<p><u>not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests targeting a sodium intake &lt;2 grams of sodium per day (or &lt;90 mmol of sodium per day, or &lt;5 grams of sodium chloride per day) in patients with high BP and CKD.</li> <li>The Work Group suggests that patients with high BP and CKD be advised to undertake moderate-intensity physical activity for a cumulative duration of at least 150 minutes per week, or to a level compatible with their cardiovascular and physical tolerance.</li> </ul> <p><u>BP management in patients with CKD, with or without diabetes, not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests that adults with high BP and CKD be treated with a target systolic BP (SBP) of &lt;120 mmHg, when tolerated, using standardized office BP measurement.</li> <li>The Work Group recommends starting renin-angiotensin-system inhibitors (RASi) (angiotensin-converting enzyme inhibitor [ACEi] or angiotensin II receptor blocker [ARB]) for people with high BP, CKD, and severely increased albuminuria without diabetes.</li> <li>The Work Group suggests starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately increased albuminuria without diabetes.</li> <li>The Work Group recommends starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately-to-severely increased albuminuria with diabetes.</li> <li>The Work Group recommends avoiding any combination of ACEi, ARB, and direct renin inhibitor (DRI) therapy in patients with CKD, with or without diabetes.</li> </ul> <p><u>BP management in kidney transplant recipients</u></p> <ul style="list-style-type: none"> <li>Treat adults kidney transplant recipients with high BP to a target BP of &lt;130 mmHg systolic and &lt;80 mmHg diastolic using standardized office BP measurement.</li> <li>The Work Group recommends that a dihydropyridine calcium channel blocker (CCB) or an ARB be used as the first-line antihypertensive agent in adult kidney transplant recipients.</li> </ul> <p><u>BP management in children with CKD</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests that in children with CKD, 24-hour mean arterial pressure by ABPM should be lowered to &lt;50<sup>th</sup> percentile for age, sex, and height.</li> </ul>
<p>American College of Cardiology/ American Heart Association Task Force: <b>Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults (2017)<sup>16</sup></b></p>	<p><u>Initiation of Blood Pressure (BP) Treatment for Overall Cardiovascular Disease (CVD) Risk</u></p> <ul style="list-style-type: none"> <li>Use of BP-lowering medications is recommended for secondary prevention of recurrent CVD events in patients with clinical CVD and an average systolic blood pressure (SBP) ≥130 mmHg or an average diastolic blood pressure (DBP) of ≥80 mmHg and for primary prevention in adults with an estimated 10-year atherosclerotic cardiovascular disease (ASCVD) risk of ≥10% and an average SBP of ≥130 mmHg or an average ≥80 mmHg.</li> <li>Use of BP-lowering medication is recommended for primary prevention of CVD in adults with no history of CVD and with an estimated 10-year ASCVD risk &lt;10% and an SBP of ≥140 mmHg or a DBP of ≥90 mmHg.</li> <li>Simultaneous use of an angiotensin converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), and/or renin inhibitor is potentially harmful and is not recommended to treat adults with hypertension.</li> <li>For adults with confirmed hypertension and known CVD or 10-year ASCVD risk of ≥10%, a BP target &lt;130/80 mmHg is recommended. For adults with confirmed hypertension without additional markers of increased CVD risk, a BP target &lt;130/80 mmHg may be reasonable.</li> <li>For initiation of antihypertensive drug therapy, first-line agents include thiazide</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>diuretics, calcium channel blockers (CCBs), and ACE inhibitors or ARBs.</p> <ul style="list-style-type: none"> <li>• Initiation of antihypertensive drug therapy with two first-line agents of different classes, either as separate agents or in a fixed-dose combination, is recommended in adults with stage 2 hypertension and an average BP &gt;20/10 mmHg above their BP target.</li> <li>• Initiation of antihypertensive drug therapy with a single antihypertensive drug is reasonable in adults with stage 1 hypertension and BP goal &lt;130/80 mmHg with dosage titration and sequential addition of other agents to achieve the BP target.</li> </ul> <p><u>Stable Ischemic Heart Disease (SIHD)</u></p> <ul style="list-style-type: none"> <li>• In adults with SIHD and hypertension, a BP target &lt;130/80 is recommended.</li> <li>• Adults with SIHD and hypertension (BP ≥130/80 mmHg) should be treated with medications [e.g., guideline-directed medical therapy (GDMT) beta-blockers, ACE inhibitors, or ARBs] for compelling indications [e.g., previous myocardial infarction (MI), stable angina] as first-line therapy, with the addition of other drugs (e.g., dihydropyridine CCBs, thiazide diuretics, and/or mineralocorticoid receptor antagonists) as needed to further control hypertension.</li> <li>• In adults with SIHD with angina and persistent uncontrolled hypertension, the addition of dihydropyridine CCBs to GDMT beta-blockers is recommended.</li> <li>• In adults who have had a MI or acute coronary syndrome, it is reasonable to continue GDMT beta-blockers beyond three years as long-term therapy for hypertension.</li> <li>• Beta-blockers and/or CCBs might be considered to control hypertension in patients with coronary artery disease (CAD) had an MI more than three years ago and have angina.</li> </ul> <p><u>Heart Failure</u></p> <ul style="list-style-type: none"> <li>• In adults with increased risk of HF, the optimal BP in those with hypertension should be &lt;130 mmHg.</li> <li>• Adults with HFrEF and hypertension should be prescribed GDMT titrated to attain a BP &lt;130/80 mmHg.</li> <li>• Non-dihydropyridine CCBs are not recommended in the treatment of hypertension in adults with HFrEF.</li> <li>• In adults with HFpEF who present with symptoms of volume overload, diuretics should be prescribed to control hypertension.</li> <li>• Adults with HFpEF and persistent hypertension after management of volume overload should be prescribed ACE inhibitors or ARBs and beta-blockers titrated to attain SBP &lt;130 mmHg.</li> </ul> <p><u>CKD</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and CKD should be treated to a BP goal &lt;130/80 mmHg.</li> <li>• In adults with hypertension and CKD [stage 3 or higher or stage 1 or 2 with albuminuria (≥300 mg/d, or ≥300 mg/g albumin-to-creatinine ratio or the equivalent in the first morning void)], treatment with an ACE inhibitor is reasonable to slow kidney disease progression. Treatment with an ARB may be reasonable if an ACE inhibitor is not tolerated.</li> <li>• After kidney transplantation, it is reasonable to treat patients with hypertension to a BP goal &lt;130/80 mmHg and with a CCB on the basis of improved glomerular filtration rate (GFR) and kidney survival.</li> </ul> <p><u>Cerebrovascular Disease</u></p> <ul style="list-style-type: none"> <li>• In adults with intracerebral hemorrhage (ICH) who present with SBP &gt;220 mmHg, it is reasonable to use continuous intravenous (IV) drug infusion and close BP monitoring to lower levels. Immediate lowering of SBP to &lt;140 mmHg in adults with spontaneous ICH who present within six hours of the acute event and have an</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>SBP between 150 mmHg and 220 mmHg is not of benefit to reduce death or severe disability and can be potentially harmful.</p> <ul style="list-style-type: none"> <li>• Adults with acute ischemic stroke and elevated BP who are eligible for treatment with IV tissue plasminogen activator (tPA) should have their BP slowly lowered to &lt;185/110 mmHg before thrombolytic therapy is initiated.</li> <li>• In adults with an acute ischemic stroke, BP should be &lt;185/110 mmHg before administration of IV tPA and should be maintained below 180/105 mmHg for at least the first 24 hours after initiation drug therapy.</li> <li>• Starting or restarting antihypertensive therapy during hospitalization in patients with BP &gt;140/90 mmHg who are neurologically stable is safe and reasonable to improve long-term BP control, unless contraindicated.</li> <li>• In patient with BP <math>\geq</math>220/120 mmHg who did not receive IV alteplase or endovascular treatment and have no comorbid conditions requiring acute antihypertensive treatment, the benefit of initiating or reinitiating treatment of hypertension within the first 48 to 72 hours is uncertain. It might be reasonable to lower BP by 15% during the first 24 hours after onset of stroke. In patients with BP &lt;220/120 mmHg with the same conditions, initiating or reinitiating treatment of hypertension within the first 48 to 72 hours after an acute ischemic stroke is not effective to prevent death or dependency.</li> <li>• Adults with previously treated stroke or transient ischemic attack should be restarted on antihypertensive treatment after the first few days of the index event to reduce the risk of recurrent stroke and other vascular events. Treatment with a thiazide diuretic, ACE inhibitor, or ARB, or combination treatment consisting of a thiazide diuretic plus ACE inhibitor, is useful.</li> <li>• Adults not previously treated for hypertension who experienced a stroke or transient ischemic attack and have an established BP <math>\geq</math>140/90 mmHg should be prescribed antihypertensive treatment a few days after the index event to reduce the risk of recurrent stroke and other vascular event.</li> <li>• For adults who experience a stroke or transient ischemic attack, selection of specific drugs should be individualized on the basis of patient comorbidities and agent pharmacological class.</li> <li>• For adults who experience a stroke or transient ischemic attack, a BP goal &lt;130/80 mmHg may be reasonable.</li> <li>• For adults with a lacunar stroke, a target SBP goal &lt;130 mmHg may be reasonable.</li> <li>• In adults previously untreated for hypertension who experience an ischemic stroke or transient ischemic attack and have an SBP &lt;140 mmHg and a DBP &lt;90 mmHg, the usefulness of initiating antihypertensive treatment is not well established.</li> </ul> <p><u>Peripheral Artery Disease (PAD)</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and PAD should be treated similarly to patients with hypertension without PAD.</li> </ul> <p><u>Diabetes Mellitus (DM)</u></p> <ul style="list-style-type: none"> <li>• In adults with DM and hypertension, antihypertensive drug treatment should be initiated at a BP of <math>\geq</math>130/80 mmHg with a treatment goal &lt;130/80 mmHg.</li> <li>• In adults with DM and hypertension, all first-line classes of antihypertensive agents (i.e., diuretics, ACE inhibitors, ARBs, and CCBs) are useful and effective.</li> <li>• In adults with DM and hypertension, ACE inhibitors or ARBs may be considered in the presence of albuminuria.</li> </ul> <p><u>Atrial Fibrillation, Valvular Heart Disease, and Aortic disease</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension can be useful for prevention of recurrence of AF.</li> <li>• In adults with asymptomatic aortic stenosis, hypertension should be treated with pharmacotherapy, starting at a low dose and gradually titrating upward as needed.</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• In patients with chronic aortic insufficiency, treatment of systolic hypertension with agents that do not slow the heart rate (i.e., avoid beta-blockers) is reasonable.</li> <li>• Beta-blockers are recommended as the preferred antihypertensive agents in patients with hypertension and thoracic aortic disease.</li> </ul> <p><u>Racial and Ethnic Differences in Treatment</u></p> <ul style="list-style-type: none"> <li>• In black adults with hypertension but without HF or CKD, including those with DM, initial antihypertensive treatment should include a thiazide-type diuretic or CCB. Two or more antihypertensive medications are recommended to achieve a BP target &lt;130/80 mmHg in most adults with hypertension, especially in black adults with hypertension.</li> </ul> <p><u>Pregnancy</u></p> <ul style="list-style-type: none"> <li>• Women with hypertension who become pregnant, or are planning to become pregnant, should be transitioned to methyldopa, nifedipine, and/or labetalol during pregnancy.</li> <li>• Women with hypertension who become pregnant should not be treated with ACE inhibitors, ARBs, or direct renin inhibitors.</li> </ul> <p><u>Older Persons</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension with an SBP treatment goal &lt;130 mmHg is recommended for noninstitutionalized ambulatory community-dwelling adults (<math>\geq 65</math> years of age) with an average SBP of <math>\geq 130</math> mmHg.</li> <li>• For older adults (<math>\geq 65</math> years of age) with hypertension and a higher burden of comorbidity and limited life expectancy, clinical judgment, patient preference, and a team-based approach to assess risk/benefit is reasonable for decisions regarding intensity of BP lowering and choice of antihypertensive drugs.</li> </ul> <p><u>Hypertensive Crises</u></p> <ul style="list-style-type: none"> <li>• In adults with a hypertensive emergency, admission to an intensive care unit is recommended for continuous monitoring of BP and target organ damage and for parenteral administration of an appropriate agent.</li> <li>• For adults with a compelling condition (i.e., aortic dissection, severe pre-eclampsia or eclampsia, or pheochromocytoma crisis), SBP should be reduced to &lt;140 mmHg during the first hour and to &lt;120 mmHg in aortic dissection.</li> <li>• For adults without a compelling condition, SBP should be reduced by no more than 25% within the first hours; then, if stable, to 160/100 mmHg within the next two to six hours; and then cautiously to normal during the following 24 to 48 hours.</li> </ul> <p><u>Cognitive Decline and Dementia</u></p> <ul style="list-style-type: none"> <li>• In adults with hypertension, BP lowering is reasonable to prevent cognitive decline and dementia.</li> </ul> <p><u>Patients Undergoing Surgical Procedures</u></p> <ul style="list-style-type: none"> <li>• In patients with hypertension undergoing major surgery who have been on beta-blockers chronically, beta-blockers should be continued.</li> <li>• In patients with hypertension undergoing planned elective major surgery, it is reasonable to continue medical therapy for hypertension until surgery.</li> <li>• In patients with hypertension undergoing major surgery, discontinuation of ACE inhibitors or ARBs perioperatively may be considered.</li> <li>• In patients with planned elective major surgery and SBP <math>\geq 180</math> mmHg or DBP <math>\geq 110</math> mmHg, deferring surgery may be considered.</li> <li>• For patients undergoing surgery, abrupt pre-operative discontinuation of beta-blockers or clonidine is potentially harmful.</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• Beta-blockers should not be started on the day of surgery in beta-blocker-naïve patients.</li> <li>• Patients with intraoperative hypertension should be managed with IV medications until such time as oral medications can be resumed.</li> </ul>
<p>American Diabetes Association: <b>Standards of Medical Care in Diabetes (2022)</b><sup>17</sup></p>	<p><b>Hypertension/blood pressure control</b></p> <ul style="list-style-type: none"> <li>• Blood pressure should be measured at every routine visit. When possible, patients found to have elevated blood pressure (<math>\geq 140/90</math>) should have blood pressure confirmed using multiple readings, including measurements on a separate day, to diagnose hypertension. Patients with blood pressure <math>\geq 180/110</math> and cardiovascular disease could be diagnosed with hypertension at a single visit.</li> <li>• All hypertensive patients with diabetes should monitor their blood pressure at home.</li> <li>• For patients with diabetes and hypertension, with diabetes and hypertension, blood pressure targets should be individualized through a shared decision-making process that addresses cardiovascular risk, potential adverse effects of antihypertensive medications, and patient preferences.</li> <li>• For individuals with diabetes and hypertension at higher cardiovascular risk (existing atherosclerotic cardiovascular disease [ASCVD] or 10-year ASCVD risk <math>\geq 15\%</math>), a blood pressure target of <math>&lt;130/80</math> mmHg may be appropriate, if it can be safely attained.</li> <li>• For individuals with diabetes and hypertension at lower risk for cardiovascular disease (10-year atherosclerotic cardiovascular disease risk <math>&lt;15\%</math>), treat to blood pressure target of <math>&lt;140/90</math>.</li> <li>• In pregnant patients with diabetes and preexisting hypertension, a blood pressure target of 110 to 135/85 is suggested in the interest of reducing the risk for accelerated maternal hypertension and minimizing impaired fetal growth.</li> <li>• For patients with blood pressure <math>&gt;120/80</math>, lifestyle intervention consists of weight loss when indicated, a Dietary Approaches to Stop Hypertension (DASH)-style eating pattern including reducing sodium and increasing potassium intake, moderation of alcohol intake, and increased physical activity.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq 140/90</math> mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of pharmacologic therapy to achieve blood pressure goals.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq 160/100</math> mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of two drugs or a single pill combination of drugs demonstrated to reduce cardiovascular events in patients with diabetes.</li> <li>• Treatment for hypertension should include drug classes demonstrated to reduce cardiovascular events in patients with diabetes (ACE inhibitors, angiotensin receptor blockers, thiazide-like diuretics, or dihydropyridine calcium channel blockers). ACE inhibitors or angiotensin receptor blockers are recommended first-line therapy for hypertension in people with diabetes and coronary artery disease.</li> <li>• Multiple-drug therapy is generally required to achieve blood pressure targets (but not a combination of ACE inhibitors and angiotensin receptor blockers).</li> <li>• An ACE inhibitor or angiotensin receptor blocker, at the maximum tolerated dose indicated for blood pressure treatment, is the recommended first-line treatment for hypertension in patients with diabetes and urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine or 30 to 299 mg/g creatinine. If one class is not tolerated, the other should be substituted.</li> <li>• For patients treated with an ACE inhibitor, angiotensin receptor blocker, or diuretic, serum creatinine/estimated glomerular filtration rate and serum potassium levels should be monitored at least annually.</li> <li>• Patients with hypertension who are not meeting blood pressure targets on three classes of antihypertensive medications (including a diuretic) should be considered for mineralocorticoid receptor antagonist therapy.</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><b>Chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>• At least once a year, assess urinary albumin (e.g., spot urinary albumin-to-creatinine ratio) and estimated glomerular filtration rate in patients with type 1 diabetes with duration of five or more years and in all patients with type 2 diabetes.</li> <li>• Patients with diabetes and urinary albumin <math>\geq 300</math> mg/g creatinine and/ or an estimated glomerular filtration rate 30 to 60 mL/min/1.73 m<sup>2</sup> should be monitored twice annually to guide therapy.</li> <li>• Optimize glucose control to reduce the risk or slow the progression of chronic kidney disease (CKD).</li> <li>• For patients with type 2 diabetes and diabetic kidney disease, use of a sodium-glucose cotransporter 2 inhibitor in patients with an estimated glomerular filtration rate <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> and urinary albumin <math>\geq 300</math> mg/g creatinine is recommended to reduce CKD progression and cardiovascular events.</li> <li>• In patients with type 2 diabetes and CKD, consider use of sodium-glucose cotransporter 2 inhibitors additionally for cardiovascular risk reduction when estimated glomerular filtration rate and urinary albumin creatinine are <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> or <math>\geq 300</math> mg/g, respectively.</li> <li>• In patients with CKD who are at increased risk for cardiovascular events or CKD progression and are unable to use a sodium-glucose cotransporter 2 inhibitor, a nonsteroidal mineralocorticoid receptor antagonist (finerenone) is recommended to reduce CKD progression and cardiovascular events.</li> <li>• Optimize blood pressure control and reduce blood pressure variability to reduce the risk or slow the progression of CKD.</li> <li>• Do not discontinue renin-angiotensin system blockade for minor increases in serum creatinine (<math>\leq 30\%</math>) in the absence of volume depletion.</li> <li>• For people with nondialysis-dependent stage 3 or higher CKD, dietary protein intake should be a maximum of 0.8 g/kg body weight per day (the recommended daily allowance). For patients on dialysis, higher levels of dietary protein intake should be considered, since malnutrition is a major problem in some dialysis patients.</li> <li>• In nonpregnant patients with diabetes and hypertension, either an ACE inhibitor or an angiotensin receptor blocker is recommended for those with modestly elevated urinary albumin-to-creatinine ratio (30 to 299 mg/g creatinine) and is strongly recommended for those with urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine and/or estimated glomerular filtration rate <math>&lt; 60</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Periodically monitor serum creatinine and potassium levels for the development of increased creatinine or changes in potassium when ACE inhibitors, angiotensin receptor blockers, or diuretics are used.</li> <li>• An ACE inhibitor or an angiotensin receptor blocker is not recommended for the primary prevention of CKD in patients with diabetes who have normal blood pressure, normal urinary albumin-to-creatinine ratio (<math>&lt; 30</math> mg/g creatinine), and normal estimated glomerular filtration rate.</li> <li>• Patients should be referred for evaluation by a nephrologist if they have an estimated glomerular filtration rate <math>&lt; 30</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Promptly refer to a nephrologist for uncertainty about the etiology of kidney disease, difficult management issues, and rapidly progressing kidney disease.</li> </ul>
<p>American Association for the Study of Liver Diseases: <b>Diagnosis, Evaluation, and Management of</b></p>	<p><b>Treatment of ascites</b></p> <ul style="list-style-type: none"> <li>• Moderate sodium restriction (2 g or 90 mmol/day) and diuretics (spironolactone with or without furosemide) are the first-line treatment in patients with cirrhosis and grade 2 ascites.</li> <li>• After ascites is adequately mobilized, attempts should be made to taper the diuretics to the lowest dose necessary to maintain minimal or no ascites to prevent the development of adverse effects.</li> </ul>

Clinical Guideline	Recommendation(s)
Ascites, Spontaneous Bacterial Peritonitis and Hepatorenal Syndrome: 2021 Practice Guidance (2021) <sup>18</sup>	<ul style="list-style-type: none"> <li>Fluid restriction is not necessary unless serum sodium is &lt;125 mmol/L.</li> <li>In patients receiving diuretics, body weight and serum creatinine and sodium should be regularly monitored to assess response and to detect the development of adverse effects.</li> <li>Human albumin solution (20 to 40 g/week) or baclofen administration (10 mg/day, with a weekly increase of 10 mg/day, up to 30 mg/day) can be considered in cases of severe muscle cramps.</li> <li>Large-volume paracentesis is the first-line treatment of grade 3 ascites. After paracentesis, sodium restriction and diuretics should be started.</li> <li>Referral for liver transplant evaluation should be considered in patients with grade 2 or 3 ascites.</li> <li>Nonsteroidal anti-inflammatory drugs, angiotensin-converting enzyme inhibitors, and angiotensin receptor blockers should be avoided in patients with cirrhosis and ascites.</li> <li>Aminoglycosides should be avoided whenever possible in the treatment of bacterial infections.</li> <li>For patients with cirrhosis and diuretic-responsive ascites, controversial data suggest potential benefits of long-term infusion of human albumin solution. At present, no recommendation can be made for its use in routine clinical practice.</li> </ul>

### III. Indications

The Food and Drug Administration (FDA)-approved indications for the thiazide diuretics are noted in Table 3. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 3. FDA-Approved Indications for the Thiazide Diuretics<sup>1-4</sup>**

Indication	Chlorothiazide*	HCTZ*
<b>Edema</b>		
Adjunctive therapy in edema associated with congestive heart failure, hepatic cirrhosis, and corticosteroid and estrogen therapy	✓	✓ (tablet)
<b>Hypertension</b>		
Treatment of hypertension	✓ † (oral)	✓ †

\*Has been found useful in edema due to various forms of renal dysfunction such as nephrotic syndrome, acute glomerulonephritis, and chronic renal failure.

†Alone or in combination with other antihypertensive agents.

HCTZ=hydrochlorothiazide

### IV. Pharmacokinetics

The pharmacokinetic parameters of the thiazide diuretics are listed in Table 4.

**Table 4. Pharmacokinetic Parameters of the Thiazide Diuretics<sup>5</sup>**

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life
Chlorothiazide	Poor	Not reported	Not metabolized	Renal (96)	45 to 120 minutes
HCTZ	60 to 80	40	Not metabolized	Renal (50 to 70)	10 to 12 hours

HCTZ=hydrochlorothiazide

## V. Drug Interactions

Major drug interactions with the thiazide diuretics are listed in Table 5.

**Table 5. Major Drug Interactions with the Thiazide Diuretics<sup>5</sup>**

Generic Name(s)	Interaction	Mechanism
Thiazide diuretics (chlorothiazide, HCTZ)	Amphetamines	Concurrent use of amphetamines and thiazide diuretics may result in increased exposure to amphetamine.
Thiazide diuretics (chlorothiazide, HCTZ)	Digitalis glycosides	Thiazide diuretics may induce electrolyte disturbances which may predispose patients to digitalis-induced arrhythmias.
Thiazide diuretics (chlorothiazide, HCTZ)	Dofetilide	Thiazide diuretics may induce hypokalemia which may increase the risk of torsades de pointes.
Thiazide diuretics (chlorothiazide, HCTZ)	Lithium	Thiazide diuretics may promote enhanced proximal tubular reabsorption of lithium leading to elevated serum concentrations. Thiazide diuretics may increase the therapeutic and toxic effects of lithium.
Thiazide diuretics (chlorothiazide, HCTZ)	Loop diuretics	Both groups have synergistic effects that may result in profound diuresis and serious electrolyte abnormalities
Thiazide diuretics (chlorothiazide, HCTZ)	NSAIDs	Concurrent use of NSAIDs and thiazide diuretics may result in reduced diuretic effectiveness and possible nephrotoxicity.
Thiazide diuretics (chlorothiazide)	Bepridil	Concurrent use of chlorothiazide and bepridil may result in hypokalemia and subsequent cardiotoxicity (torsades de pointes).
Chlorothiazide	Flecainide	Concurrent use of chlorothiazide and flecainide may result in increased risk of electrolyte imbalance and subsequent cardiotoxicity.
Hydrochlorothiazide	Methotrexate	Concurrent use of hydrochlorothiazide and methotrexate may result in increased methotrexate exposure and enhanced myelosuppression.

HCTZ=hydrochlorothiazide, NSAIDs=nonsteroidal anti-inflammatory drugs

## VI. Adverse Drug Events

The most common adverse drug events reported with the thiazide diuretics are listed in Table 6.

## VII. Dosing and Administration

The usual dosing regimens for the thiazide diuretics are listed in Table 7.

**Table 7. Usual Dosing Regimens for the Thiazide Diuretics<sup>1-5</sup>**

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
Chlorothiazide	<p><u>Edema:</u> Injection, suspension, tablet: 0.5 to 1 g once or twice daily, often administered on alternate days or on three to five days each week</p> <p><u>Hypertension:</u> Injection, suspension, tablet: initial, 0.5 or 1 g/day as a single dose or in divided dose(s); maintenance, adjust according to blood pressure response, some patients may require up to 2 g/day in divided doses</p>	<p><u>Diuresis and hypertension:</u> Suspension, tablet: the usual pediatric dosage is 5 to 10 mg per pound (10 to 20 mg/kg) per day in single or two divided doses, not to exceed 375 mg per day in infants up to 2 years of age or 1 g per day in children 2 to 12 years of age. In infants less than 6 months of age, doses up to 15 mg per pound (30 mg/kg) per day in two divided doses may be required</p>	<p>Injection: 500 mg</p> <p>Suspension 250 mg/5 mL</p> <p>Tablet: 250 mg 500 mg</p>
HCTZ	<p><u>Edema:</u> Capsule, tablet: maintenance, 25 to 100 mg/day in a single or divided dose(s)</p> <p><u>Hypertension:</u> Capsule, tablet: initial, 12.5 to 25 mg once daily; maintenance, 50 to 100 mg daily in a single or divided dose(s)</p>	<p><u>Diuresis and hypertension:</u> Tablet: the usual pediatric dosage is 0.5 to 1 mg per pound (1 to 2 mg/kg) per day in single or two divided doses, not to exceed 37.5 mg per day in infants up to 2 years of age or 100 mg per day in children 2 to 12 years of age. In infants less than 6 months of age, doses up to 1.5 mg per pound (3 mg/kg) per day in two divided doses may be required.</p>	<p>Capsule: 12.5 mg</p> <p>Tablet: 12.5 mg 25 mg 50 mg</p>

HCTZ=hydrochlorothiazide

## VIII. Effectiveness

Clinical studies evaluating the safety and efficacy of the thiazide diuretics are summarized in Table 8.

**Table 8. Comparative Clinical Trials with the Thiazide Diuretics**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<b>Edema</b>				
Rengo et al. <sup>19</sup> (1979)  HCTZ 150 mg QD  vs  amiloride 15 mg QD  vs  amiloride and HCTZ 15-150 mg QD (fixed-dose combination product)	RCT  Patients 35 to 60 years of age with liver cirrhosis and ascites or CHF	N=30  15 days	Primary: Body weight, 24 hour diuresis, serum sodium, serum potassium, sodium and potassium urinary loss  Secondary: Not reported	Primary: All treatment groups had a significant reduction in body weight from baseline (P<0.001 for all). Amiloride and HCTZ-treated patients achieved a significantly greater reduction compared to amiloride-treated patients (P<0.001).  All treatment groups significantly differed from baseline in 24 hour diuresis (P<0.01). Amiloride and HCTZ- and HCTZ-treated patients achieved greater diuresis compared to amiloride-treated patients (P<0.001 for both).  Serum sodium was reduced from baseline in all treatment groups. HCTZ-treated patients had a significantly greater reduction than amiloride- (P<0.01) and amiloride and HCTZ-treated patients (P<0.001). Sodium urinary loss was seen with all treatments at day two, amiloride and HCTZ therapy had maintained the loss at day five (P<0.001 for both).  Serum potassium decreased in HCTZ-treated patients but increased in amiloride- and amiloride and HCTZ-treated patients. HCTZ-treated patients had a marked increase in potassium urinary loss (P<0.001).  Secondary: Not reported
Cheitlin et al. <sup>20</sup> (1991)  Amiloride 5 or 10 mg QD for 7 days, followed by placebo plus HCTZ 50 or 100	DB, PC, RCT, XO  Patients with a history CHF and ≥1 episode of pulmonary edema (NYHA class 2 to 3) who were not	N=11  21 days	Primary: Hemodynamic changes at rest and exercise  Secondary: Not reported	Primary: At rest, there were no significant differences between placebo- and amiloride-treated patients in right atrial pressure, pulmonary atrial pressure, heart rate, pulmonary artery wedge pressure, systemic arterial pressure, right ventricular stroke work index, left ventricular stroke work index, systemic vascular resistance, cardiac index or stroke volume index (P values not reported).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>mg QD for 14 days</p> <p>vs</p> <p>placebo for 14 days, followed by amiloride 5 or 10 mg plus HCTZ 50 or 100 mg QD for the next 7 days</p>	<p>previously treated</p>			<p>During exercise, there were significant differences between placebo- and amiloride-treated patients at the 50-watt stage in right atrial pressure (15.0 vs 10.5 mm Hg), pulmonary artery wedge pressure (28.6 vs 22.1 mm Hg), pulmonary artery diastolic pressure (32.2 vs 21.6 mm Hg), mean pulmonary artery pressure (44.4 vs 38.9 mm Hg), left ventricular stroke work index (69.5 vs 77.9 g-m/m<sup>2</sup>) and stroke volume index (44.9 vs 46.2 cc/beat/m<sup>2</sup>), respectively (P values not reported).</p> <p>There were no significant differences between placebo and amiloride therapy during exercise in right ventricular stroke work index, heart rate, aortic pressure, cardiac index and total systemic vascular resistance (P values not reported).</p> <p>Secondary: Not reported</p>
<p>Kohvakka<sup>21</sup> (1988)</p> <p>HCTZ 50 mg BID</p> <p>vs</p> <p>amiloride 5 mg BID plus HCTZ 50 mg BID</p> <p>vs</p> <p>triamterene 75 mg BID plus HCTZ 50 mg BID</p> <p>vs</p> <p>KCl 1,000 mg BID plus HCTZ 50 mg BID</p>	<p>RCT, XO</p> <p>Patients 41 to 69 years of age with CHF (NYHA class 2 to 3) who developed persistent hypokalemia on HCTZ alone</p>	<p>N=25</p> <p>5 months</p>	<p>Primary: Changes in weight, blood pressure, serum sodium, serum potassium and total body potassium</p> <p>Secondary: Percentage with hypokalemia, median days until hypokalemia detection, serum magnesium</p>	<p>Primary: Weight loss was significant in amiloride plus HCTZ- and triamterene plus HCTZ-treated patients (P=0.05 for both), but not in KCl plus HCTZ-treated patients (P value not reported), compared to HCTZ-treated patients.</p> <p>No significant changes in blood pressure were observed (P values not reported).</p> <p>No differences in serum sodium were observed in amiloride plus HCTZ- or triamterene plus HCTZ-treated patients (P values not reported). Serum sodium levels were slightly higher in KCl plus HCTZ-patients compared to HCTZ-treated patients (P=0.01).</p> <p>Serum potassium was found to be significantly higher in all combination treated-patients compared to HCTZ-treated patients (P=0.01 for all comparisons). Total body potassium was significantly higher in amiloride plus HCTZ- and triamterene plus HCTZ-treated patients (P=0.05 for both), but not in KCl plus HCTZ-treated patients (P value not reported), compared to HCTZ-treated patients.</p> <p>Secondary:</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>The percentages of patients that became hypokalemic were 39, 52 and 52% in amiloride plus HCTZ-, triamterene plus HCTZ- and KCl plus HCTZ-treated patients (P values not reported).</p> <p>The median days until hypokalemia detection were 114.0, 75.0 and 51.5 for amiloride plus HCTZ-, triamterene plus HCTZ- and KCl plus HCTZ-treated patients (P values not reported).</p> <p>Serum magnesium was maintained at a significantly higher rate in amiloride plus HCTZ- and triamterene plus HCTZ- patients compared to KCl plus HCTZ-treated patients (P values not reported).</p>
<p>Faris et al.<sup>22</sup> (2006)</p> <p>Thiazide diuretics (chlorothiazide), loop diuretics (furosemide, bumetanide), or potassium-sparing diuretics (amiloride, triamterene)</p> <p>vs</p> <p>placebo or active control (ACE inhibitors, digoxin)</p>	<p>MA (14 trials)</p> <p>Adult patients with chronic heart failure</p>	<p>N=525</p> <p>2 to 52 weeks</p>	<p>Primary: Mortality</p> <p>Secondary: Effect of diuretic withdrawal on worsening of heart failure and exercise capacity</p>	<p>Primary: Pooled data from three PC trials (n=202) reporting on mortality revealed that mortality was lower for diuretic-treated patients compared to placebo-treated patients (2.7 vs 10.9%, respectively; OR, 0.24; 95% CI, 0.07 to 0.83; P=0.02). The difference represents an absolute risk reduction of 8% in mortality in diuretic-treated patients (NNT, 12.5).</p> <p>Secondary: Pooled data from two PC trials (n=169) reporting on the effect of diuretics on worsening heart failure revealed lower admission rates for worsening heart failure in diuretic-treated patients compared to placebo-treated patients (OR, 0.07; 95% CI, 0.01 to 0.52; P=0.01).</p> <p>Pooled data from two parallel RCTs (n=43) reporting on the effect of diuretics on exercise capacity revealed that diuretic therapy improved exercise capacity compared to active control (WMD, 0.74; 95% CI, 0.37 to 1.11; P&lt;0.0001). Pooled data from two XO RCTs (n=48) revealed similar results (WMD, 0.67; 95% CI, 0.02 to 1.31; P=0.04). In total (n=91), diuretic therapy improved exercise capacity in patients with chronic heart failure (WMD, 0.72; 95% CI, 0.40 to 1.04; P&lt;0.0001).</p>
<b>Hypertension</b>				
<p>Hua et al.<sup>23</sup> (1976)</p> <p>Chlorothiazide up to 5 g BID</p>	<p>XO</p> <p>Patients with HTN</p>	<p>N=20</p> <p>Duration not specified</p>	<p>Primary: Blood pressure, serum potassium</p> <p>Secondary:</p>	<p>Primary: Blood pressures on metolazone tended to be lower than on chlorothiazide, but the difference was not statistically significant.</p> <p>Both agents significantly lowered serum potassium concentrations and</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs metolazone 5 mg QD			Not reported	total body potassium to a similar degree. However, the serum potassium did not fall below the normal range in any patient and no potassium supplements were required.  Secondary: Not reported
Carter et al. <sup>24</sup> (2004)  HCTZ 12.5 to 450 mg/day  vs  chlorthalidone 12.5 to 600 mg/day	MA  Included trials which evaluate the pharmacokinetic and blood pressure lowering effects of chlorthalidone and HCTZ	N=200  Duration varied per study	Primary: Blood pressure  Secondary: Serum potassium	Primary: In a dose equivalence study comparing HCTZ 100 mg QD to chlorthalidone 50 mg QD, blood pressure (SBP/DBP) reduced by 18/8 and 25/10 mm Hg compared to baseline, respectively.  In another study comparing HCTZ 25 mg and triamterene 50 mg QD, HCTZ 50 mg and triamterene 100 mg QD, and chlorthalidone 50 mg QD, the blood pressure reduction was 15/8, 18/12, and 25/16 mm Hg, respectively.  One other dose equivalence study comparing HCTZ 50 mg BID and chlorthalidone 50 mg QD, blood pressure reduction was 22/16 and 18/15 mm Hg, respectively.  All available studies were inspected and it was concluded that HCTZ 50 mg is approximately equivalent to chlorthalidone 25 to 37 mg. Furthermore, it was suggested that chlorthalidone doses should generally be approximately 50% to 75% of the typical HCTZ dose.  Secondary: In a study comparing HCTZ 100 mg QD and chlorthalidone 50 mg QD, potassium increased slightly with chlorthalidone (0.02 mEq/L) and decreased significantly with HCTZ (0.22 mEq/L; P=0.009).  However, in another study comparing HCTZ 50 mg BID and chlorthalidone 50 mg QD, serum potassium decreased by 0.38 mEq/L with HCTZ and by 0.03 mEq/L with chlorthalidone. The difference was not statistically significant (P<0.07).
Ernst et al. <sup>25</sup> (2006)	RCT, SB, XO  Men and women	N=30  8 weeks plus 4	Primary: Comparison of the change in 24-hour	Primary: At week eight, there was a greater reduction in 24-hr mean SBP with chlorthalidone 25 mg/day compared to HCTZ 50 mg/day compared to

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>HCTZ 25 mg in the morning</p> <p>vs</p> <p>chlorthalidone 12.5 mg in the morning</p> <p>At week 4, both HCTZ and chlorthalidone were titrated to 50 mg in the morning and 25 mg in the morning, respectively for the remainder of the trial.</p>	<p>aged 18 to 79 years with pre-HTN or a new or established diagnosis of HTN (stage 1 or 2), not receiving antihypertensive medications, and had an average office blood pressure value in the last 6 months between 140 and 179 mm Hg systolic or 90 and 109 mm Hg diastolic</p>	<p>week washout period</p>	<p>mean SBP and DBP from baseline to week 8</p> <p>Secondary: Comparison of changes in mean SBP and mean DBP for office blood pressure at each visit, change in ambulatory daytime and nighttime mean SBP and DBP from baseline to week 8, development of hypokalemia</p>	<p>baseline (-12.4±1.8 vs -7.4±1.7 mm Hg, respectively; P=0.054).</p> <p>Secondary: There was a trend in favor of greater reduction in SBP with chlorthalidone than with HCTZ at each office visit. However, the difference was only statistically significant at week 2 (-15.7±2.2 vs -4.5±2.1 mm Hg, respectively; P=0.001).</p> <p>Although mean reductions in DBP was also greater with chlorthalidone compared to HCTZ at each study visit, the differences were not statistically significant at any visit (P&gt;0.89 for all).</p> <p>The reduction in SBP during nighttime hours was -13.5±1.9 mm Hg for chlorthalidone and -6.4±1.7 mm Hg for HCTZ (P=0.009). The reduction in daytime mean SBP between both groups was not significantly different (-11.4±2.0 vs -8.1±1.9 mm Hg, respectively; P=0.230).</p> <p>Changes in serum potassium were similar between treatment groups (P=0.76). The incidence of hypokalemia was 50% in patients taking HCTZ and 46% in patients taking chlorthalidone (P=0.682).</p>
<p>Finnerty et al.<sup>26</sup> (1980)</p> <p>HCTZ 50 mg plus reserpine 0.125 mg</p> <p>vs</p> <p>chlorthalidone 50 mg plus reserpine 0.25 mg</p>	<p>DB</p> <p>Patients with essential HTN unresponsive to diet control and diuretic therapy</p>	<p>N=57</p> <p>6 weeks</p>	<p>Primary: The change in mean DBP from baseline</p> <p>Secondary: Incidence of frequent or severe side effects</p>	<p>Primary: The chlorthalidone plus reserpine group had a mean decrease in DBP of 17.0 mm Hg at study endpoint compared with a mean decrease of 18.6 mm Hg in the HCTZ plus reserpine group.</p> <p>At study completion both treatment groups achieved diastolic control of at least 5 mm Hg below the targeted diastolic goal of 90 mm Hg.</p> <p>Secondary: There were no reports of frequent or severe side effects in either treatment group.</p>
<p>Bakris et al.<sup>27</sup> (2012)</p> <p>Azilsartan medoxomil and chlorthalidone</p>	<p>DB, RCT</p> <p>Patients aged ≥18 years with stage 2 primary HTN</p>	<p>N=609</p> <p>10 weeks (after 2 week placebo run-in)</p>	<p>Primary: Change in trough, seated clinic systolic blood pressure at weeks 6 and 10</p>	<p>Primary: Change in SBP at week six demonstrated a mean difference of -5.6 mm Hg (95% CI, -8.3 to -2.9; P&lt;0.001) in favor of the chlorthalidone group. Fewer patients in the chlorthalidone group required titration to a higher dose of diuretic (P&lt;0.001). At the end of week 10, a greater mean SBP reduction was maintained in the chlorthalidone group compared to the</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>(single pill)</p> <p>vs</p> <p>azilsartan medoxomil and HCTZ (co-administered)</p> <p>Treatments were titrated to a target of &lt;140/90 mm Hg (or &lt;130/80 mm Hg if diabetes of chronic kidney disease)</p>			<p>Secondary: Change from baseline in clinic DBP and 24-hour mean systolic and diastolic blood pressures by ambulatory blood pressure monitoring</p>	<p>HCTZ group (-5.0 mm Hg; 95% CI, -7.5 to -2.5; P&lt;0.001).</p> <p>Secondary: The chlorthalidone group demonstrated a significantly greater reduction in 24-hour mean SBP at weeks six and 10. For both clinica and 24-hour mean DBP, greater blood pressure reduction was observed in the chlorthalidone group compared to the HCTZ group at both study points.</p>
<p>Valmin et al.<sup>28</sup> (1975)</p> <p>HCTZ 12.5 mg BID</p> <p>vs</p> <p>furosemide 12.5, 25, or 40 mg BID</p> <p>vs</p> <p>placebo</p>	<p>DB, RCT, XO, 5 experimental periods each of 4 weeks</p> <p>Men and women with essential HTN</p>	<p>N=34</p> <p>20 weeks</p>	<p>Primary: Blood pressure, urinary output, serum electrolytes, safety and tolerability</p> <p>Secondary: Not reported</p>	<p>Primary: When compared to placebo, there was a significant reduction of blood pressure with HCTZ 12.5 mg BID and furosemide 12.5 mg BID (P&lt;0.05).</p> <p>Paired comparison showed that HCTZ 12.5 mg BID and furosemide 25 and 40 mg BID had a similar hypotensive effect, irrespective of the initial blood pressure (P&gt;0.10).</p> <p>When compared to placebo, the urinary output increased significantly with furosemide 12.5, 25, or 40 mg BID (P&lt;0.05, P&lt;0.01 and P&lt;0.001, respectively) but not with the HCTZ group (P&gt;0.10).</p> <p>Sodium level did not alter during the various treatment periods when compared with the placebo period, or between the individual treatment periods (P&gt;0.10).</p> <p>Potassium level fell significantly during the HCTZ period (P&lt;0.001) and furosemide 25 mg and 40 mg BID period (P&lt;0.01 and P&lt;0.001, respectively). Potassium level was not significantly affected with furosemide 12.5 mg BID (P&gt;0.10).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				Secondary: Not reported
Araoye et al. <sup>29</sup> (1978)  HCTZ 50 mg BID  vs  furosemide 40 mg BID	DB, XO  Patients with HTN	N=not specified  3 months	Primary: Blood Pressure  Secondary: Not reported	Primary: Furosemide and HCTZ significantly reduced blood pressure. The decrease in blood pressure was consistently greater in the HCTZ group than with furosemide; however the difference was significant in regards to SBP only.  Secondary: Not reported
Madkour et al. <sup>30</sup> (1996)  HCTZ 50 mg QD  vs  indapamide 2.5 mg QD	RCT  Patients aged 32 to 70 years with impaired renal function for 1 to 15 years and moderate HTN for 2 to 27 years, initial creatinine clearance between 32 and 80 mL/min/1.73 m <sup>2</sup> BSA	N=28  24 months	Primary: Blood pressure, changes in creatinine clearance  Secondary: Not reported	Primary: Blood pressure normalized in all patients taking either indapamide or HCTZ. There were no significant differences in SBP or DBP between groups.  At 24 months, creatinine clearance progressively increased from 58±4.4 to 72±4.4 mL/min/1.73 m <sup>2</sup> BSA in patients treated with indapamide (P<0.01).  Creatinine clearance progressively decreased from 65±3.0 to 53±3.0 mL/min/1.73 m <sup>2</sup> BSA in patients treated with HCTZ (P<0.01). Creatinine clearance significantly increased by 28.5±4.4% with indapamide and decreased by 17.4±3.0% with thiazide therapy (P<0.01).  Secondary: Not reported
Ames <sup>31</sup> (1996)  HCTZ ≤25 mg (or its equivalent in other thiazides) up to 112.5 mg QD  vs	MA (13 trials)  Patients with HTN	N=1,547  1 to 25 months	Primary: Comparison of the effects of thiazides and indapamide on blood lipids and blood pressure  Secondary: Not reported	Primary: The mean change from baseline was 1.4% for TC, 5.5% for HDL-C, and -0.5% for TG with indapamide. None of the differences were statistically significant.  Low-dose thiazide therapy did not decrease TC at any data point. The mean percent increase in TC was 3.8%, in HDL-C was 3.1%, and in TG was 10.8% with low-dose HCTZ. The increases in TC and TG from baseline was statistically significant (P<0.01).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
indapamide 2.5 mg QD				<p>The mean change in TC was 6.3%, in HDL-C was -0.5%, and in TGs was 19.5% for higher doses of HCTZ. Increases from baseline in TC and TG were statistically significant.</p> <p>SBP decreased more with higher doses of HCTZ than with low-dose thiazide therapy (P&lt;0.05). The effects of indapamide on systolic arterial pressure were intermediate between, and not statistically different from, either thiazide dose. Decreases in DBP did not differ among groups.</p> <p>Secondary: Not reported</p>
<p>Larochelle et al.<sup>32</sup> (1985)</p> <p>HCTZ 50 mg</p> <p>vs</p> <p>amiloride 5 mg/day and HCTZ 50 mg/day</p>	<p>DB, RCT</p> <p>Ambulant patients 18 to 70 years of age with essential HTN who after not being treated for ≥2 weeks prior to the trial had a supine DBP of 95 to 109 mm Hg and a serum potassium level of &gt;3.5 mmol/L</p>	<p>N=266</p> <p>8 weeks</p>	<p>Primary: Blood pressure, serum potassium concentration</p> <p>Secondary: Not reported</p>	<p>Primary: At eight weeks, there were no differences between the two treatments in the mean blood pressure reductions (P value not reported).</p> <p>During the eight weeks of treatment, the HCTZ plus amiloride-treated patients experienced a decrease in mean supine blood pressure (159/99 to 138/88 mm Hg) and serum potassium levels (4.23 to 3.91 mmol/L) (P values not reported).</p> <p>During the eight weeks of treatment, HCTZ-treated patients experienced a reduction in mean supine blood pressure (157/99 to 138/87 mm Hg) and serum potassium levels (4.16 to 3.69 mmol/L) (P values not reported).</p> <p>Hypokalemia occurred less frequently in HCTZ plus amiloride-treated patients compared to HCTZ-treated patients (14 and 29%, respectively; P=0.0026). However, the proportions of patients with a potassium level exceeding 4.5 mmol/L were similar (4.5 vs 3.9%, respectively; P value not reported).</p> <p>Secondary: Not reported</p>

			Secondary: Death from cardiovascular causes, nonfatal MI, and nonfatal stroke	CV event rate than those without CAD (15 vs 7%; P<0.0001).  Secondary: The composite secondary end point of CV mortality, MI, and stroke occurred in 5.74% in the B+A group and 8% in the B+H group, resulting in an absolute risk reduction of 1.95% and a hazard reduction of 25% (HR, 0.73; 95% CI, 0.59 to 0.9; P=0.033). The rate of all-cause mortality differed significantly between the treatment arms (HR, 0.77; 95% CI, 0.6 to 0.99; P=0.042). Among the patients without CAD, the rates of CV mortality, MI, and stroke did not differ between the two arms (HR, 0.86; 95% CI, 0.68 to 1.08). The secondary end point events were lower in the group of patients without CAD.
Wing et al. <sup>50</sup> (2003) ANBP2  HCTZ  vs  enalapril  The choice of the specific agent and dose was made by the family practitioner.	MC, OL, PRO, RCT  Patients 65 to 84 years of age with average SBP while sitting of $\geq 160$ mm Hg or an average DBP of $\geq 90$ mm Hg (if the SBP was $\geq 140$ mm Hg)	N=6,083  4.1 years (median)	Primary: All cardiovascular events or death from any cause (both initial and subsequent fatal and nonfatal cardiovascular events)  Secondary: Not reported	Primary: By the end of the study, blood pressure had decreased to a similar extent in both groups (a decrease of 26/12 mm Hg).  There were 695 cardiovascular events or deaths from any cause in the ACE inhibitor group (56.1 per 1,000 patient-years; HR, 0.89; 95% CI, 0.79 to 1.0; P=0.05) compared to 736 in the diuretic group (59.8 per 1,000 patient-years).  The beneficial effects of ACE inhibitor treatment were more evident in male subjects (HR, 0.83; 95% CI, 0.71 to 0.97; P=0.02).  The rates of nonfatal cardiovascular events and MI decreased with ACE inhibitor treatment, whereas a similar number of strokes occurred in each group (although there were more fatal strokes in the ACE inhibitor group).  Secondary: Not reported
Poldermans et al. <sup>51</sup> (2007)  HCTZ 12.5 mg QD and lisinopril 10 to 20 mg	AC, DB, MC, PG, RCT  Males and females, ages 18 years and older with HTN (mean DBP $\geq 110$ )	N=130  6 weeks	Primary: Safety/adverse events, vital signs, hematology, biochemistry variables	Primary: Both treatments were well tolerated, 26 (40.6%) of patients receiving amlodipine and valsartan and 21 (31.8%) of patients receiving lisinopril and HCTZ reported an adverse events and most were not considered drug related.  Peripheral edema was reported more often in the amlodipine and valsartan

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs amlodipine 5 to 10 mg QD and valsartan 160 mg QD	mm Hg and <120 mm Hg)		Secondary: Efficacy (mean DBP, response rate, proportion of patients with mean DBP <90 mm Hg or a $\geq$ 10 mm Hg reduction from baseline)	group than the lisinopril and HCTZ group (7.7 vs 1.5%) and cough was reported less often in the amlodipine and valsartan group than the receiving lisinopril and hydrochlorothiazide group (1.6 vs 3.0%).  No difference was found between the treatments in changes in laboratory values or biochemistry variables.  Secondary: Both treatments led to a reduction in mean SBP and DBP (P<0.0001 for both from baseline) but were not significantly different from each other. Mean blood pressure for each group at study end: amlodipine and valsartan 135.0/83.6 mm Hg and lisinopril and HCTZ 138.7/85.2 mm Hg.  The response rate was similar among the groups (100 vs 95.5%; P value not significant).
Fogari et al. <sup>52</sup> (2007) CANDIA  HCTZ 12.5 mg QD and candesartan 16 mg  vs amlodipine 10 mg QD	DB, MC, RCT  Patients, 20 to 80 years old, with mild to moderate uncomplicated HTN not controlled on monotherapy with an antihypertensive (SBP <180 mg Hg and DBP 90 to 110 mg Hg)	N=203  8 weeks	Primary: Decrease in DBP  Secondary: Sitting SBP, reduction of the orthostatic blood pressure at least two minutes after standing, change in heart rate, percentage of patients normalized (DBP <90 mm Hg and SBP <140 mm Hg), percentage of responders (reduction in DBP $\geq$ 5 mm Hg)	Primary: There was no significant difference in the mean decrease in DBP between treatment groups; the difference in final DBP was -0.02 mm Hg (95% CI, -1.48 to 1.52 mm Hg; P=0.979).  Secondary: There was no significant difference between the groups at week eight for the following: sitting SBP (P=0.835), heart rate (P<0.500), orthostatic SBP (P=0.883), orthostatic DBP (P=0.264), percentage of patients normalized (P=10), percentage of responders (P=0.900).  The number of patients reporting an adverse event was greater in the amlodipine group (P=0.001).  The number of patients reporting an adverse drug-related event was greater in the amlodipine group (P<0.001).  Changes in blood chemistry and other secondary measurements were not significantly different between the treatment groups.
Neutel et al. <sup>53</sup> (2008)	AC, DB, RCT	N=538	Primary: Change in SBP	Primary: At week eight, there was a reduction in SBP of 27.1 mm Hg with

<p>mg QD</p> <p>vs</p> <p>aliskiren 75 to 300 mg QD</p> <p>vs</p> <p>aliskiren and HCTZ (every dose combination except aliskiren 300 mg and HCTZ 6.25 mg) QD</p> <p>vs</p> <p>placebo</p>	<p>mild-to-moderate essential HTN</p>		<p>Secondary: Change in mean sitting SBP, dose-response efficacy for all treatment groups, proportion achieving a successful response (DBP &lt;90 mm Hg or ≥10 mm Hg), proportion achieving blood pressure control (&lt;140/90 mm Hg), plasma renin activity, renin concentrations, safety</p>	<p>significantly reduced DBP from baseline (P&lt;0.01 for all vs placebo).</p> <p>All combinations were more effective than placebo (P&lt;0.0001) with reductions in DBP ranging from 10.4 to 14.3 mm Hg. Most combination regimens were more effective than monotherapy with the individual components (exceptions were aliskiren 150 mg and HCTZ 6.25 mg vs monotherapy, and aliskiren 75 mg and HCTZ 12.5 mg vs HCTZ monotherapy).</p> <p>Secondary: After eight weeks of therapy, aliskiren 150 and 300 mg regimens (both P&lt;0.0001) were more effective than placebo in lowering mean sitting SBP, but the 75 mg dose was not (P=0.151).</p> <p>Combination therapy was consistently more effective in reducing SBP than monotherapy with the individual components, with the exception of aliskiren 75 mg plus HCTZ 12.5 vs HCTZ monotherapy. Reductions in SBP with combination therapy ranged from 14.3 to 21.2 mm Hg.</p> <p>Blood pressure reductions were related to the doses of both aliskiren and HCTZ.</p> <p>Responder rates were significantly higher with aliskiren 300 mg (63.9%; P=0.0005), HCTZ 12.5 and 25 mg (60.6 and 59.0%, respectively; both P&lt;0.02) and all combination doses (58.4 to 80.6%; all P&lt;0.05) than placebo (45.8%). Responder rates for all combinations of aliskiren and HCTZ 25 mg, and aliskiren 300 mg and HCTZ 12.5 mg were higher than both monotherapies (P&lt;0.05), while aliskiren 75 mg and HCTZ 12.5 mg and aliskiren 150 mg and HCTZ 12.5 mg were more effective than their respective aliskiren monotherapies (P&lt;0.05).</p> <p>In the aliskiren and HCTZ monotherapy groups, only aliskiren 300 mg led to statistically significantly greater control rates than placebo (46.7 vs 28.1%; P=0.0001). Control rates for all combinations, with the exception of aliskiren 75 mg and HCTZ 6.25 mg, were higher than placebo (all P&lt;0.02). There was a trend towards improved control rates with combination therapy (37.4 to 59.5%) compared to aliskiren monotherapy</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>(29.0 to 46.7%) or HCTZ monotherapy (32.5 to 37.8%). Combinations utilizing the higher doses of one or both drugs (aliskiren 75 to 300 mg with HCTZ 25 mg or aliskiren 150 to 300 mg with HCTZ 12.5 mg) yielded control rates that were significantly higher than monotherapy with either component.</p> <p>While all doses of aliskiren decreased plasma renin activity and all doses of HCTZ increased plasma renin activity, combination therapy resulted in decreased plasma renin activity of 46.1 to 63.5%. Renin concentrations increased in all monotherapy and combination regimens with the exception of HCTZ 6.25 and 12.5 mg.</p> <p>All active treatments were well tolerated with 37.3 to 39.2% of patients experiencing adverse events with aliskiren monotherapy, 38.7 to 42.0% with HCTZ monotherapy, 34.6 to 45.3% with aliskiren and HCTZ, and 44% with placebo. Hypokalemia (serum potassium &lt;3.5 mmol/L) occurred with the highest frequency with HCTZ 12.5 and 25 mg (3.9 and 5.2%, respectively). When administered in combination with aliskiren, the frequency of hypokalemia was 0.7 to 2.0% with HCTZ 12.5 mg and 2.2% to 3.4% with HCTZ 25 mg.</p>
<p>Blumenstein et al.<sup>65</sup> (2009)</p> <p>HCTZ 25 mg (existing therapy)</p> <p>vs</p> <p>aliskiren and HCTZ 300-25 mg QD (fixed-dose combination product)</p> <p>vs</p>	<p>DB, MC, RCT</p> <p>Patients with HTN and an inadequate response to HCTZ (mean sitting DBP &gt;90 and ≤110 mm Hg following 4 weeks of HCTZ 25 mg)</p>	<p>N=722</p> <p>8 weeks</p>	<p>Primary:</p> <p>Changes in mean sitting SBP/DBP, proportion of patients achieving blood pressure control (mean sitting blood pressure &lt;140/90 mm Hg), and blood pressure response rates (msDBP &lt;90 mm Hg or a ≥10 mm Hg decrease from baseline)</p>	<p>Primary:</p> <p>The mean reductions in mean sitting SBP/DBP from baseline with aliskiren and HCTZ 300-25 and 150-25 mg were significantly greater compared to those achieved with HCTZ monotherapy (P&lt;0.001 for all).</p> <p>Rates of blood pressure control were significantly higher with aliskiren and HCTZ 300-25 and 150-25 mg compared to HCTZ monotherapy (P&lt;0.001 for both).</p> <p>Aliskiren and HCTZ 300-25 mg provided significantly greater reductions in mean sitting SBP/DBP and rates of blood pressure control compared to aliskiren and HCTZ 150-25 mg dose (P&lt;0.05 for all).</p> <p>Blood pressure response rates were significantly higher with aliskiren and HCTZ 300-25mg (78.5%) and aliskiren and HCTZ 150-25 mg (67.4%) compared to HCTZ monotherapy (47.1%; P&lt;0.001 for both comparisons).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
aliskiren and HCTZ 150-25 mg QD (fixed-dose combination product)			Secondary: Not reported	<p>All treatments were generally well-tolerated and the proportion of patients experiencing adverse events was similar across treatment groups. The majority of adverse events were mild and transient. Adverse events reported in &gt;2% of patients were nasopharyngitis, dizziness, back pain, and vertigo.</p> <p>The proportion of patients with serum potassium &lt;3.5 mmol/L was lower with aliskiren and HCTZ (1.3 to 2.2%) compared to HCTZ monotherapy (3.4%). Hyperkalemia (serum potassium &gt;5.5 mmol/L) was observed in only one patient receiving aliskiren and HCTZ and two patients in the HCTZ monotherapy group. No patient had increases in serum creatinine above the pre-specified clinically significant threshold.</p> <p>Secondary: Not reported</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs  irbesartan 150 to 300 mg QD, added to existing HCTZ therapy (single entity products)			patients achieving blood pressure control (mean sitting blood pressure <140/90 mm Hg), plasma renin activity, safety and tolerability	of HCTZ monotherapy. Combination with aliskiren neutralized this increase and led to an overall significant reduction in plasma renin activity compared with pretreatment baseline (P<0.05) whereas amlodipine and irbesartan led to further significant increases (P<0.05).  All of the study treatments were generally well tolerated. Amlodipine plus HCTZ (45.2%) was associated with a higher incidence of adverse events than the other treatment groups (36.1 to 39.3%), largely due to a higher rate of peripheral edema (11.1 vs 0.8 to 1.6%).
Geiger et al. <sup>67</sup> (2009)  HCTZ 25 mg QD  vs  aliskiren 150 to 300 mg QD, added to existing HCTZ therapy  vs  valsartan 160 to 320 mg QD, added to existing HCTZ therapy  vs  aliskiren 150 to 300 mg and valsartan 160 to 320 mg QD, added to existing HCTZ therapy	AC, DB, RCT  Patients ≥18 years of age with mild to moderate essential HTN who were taking HCTZ for 4 weeks with a DBP ≥95 mm Hg	N=641  8 weeks	Primary: Change in DBP at week 8  Secondary: Change SBP at week 8, change in DBP and SBP at week 4, proportion of patients achieving blood pressure control (SBP/DBP <140/90 mm Hg), change in plasma renin activity, plasma renin concentration	Primary: After eight weeks of therapy, the triple therapy showed significantly greater reductions in SBP and DBP compared with the other groups. The additional SBP and DBP reductions were 7 and 5 mm Hg, respectively compared to aliskiren and HCTZ (P<0.0001), 3 and 2 mm Hg compared to valsartan and HCTZ (P<0.01), and 15 and 10 mm Hg compared to HCTZ monotherapy (P<0.001).  Aliskiren and HCTZ and valsartan and HCTZ combination therapies were more effective compared to HCTZ monotherapy. Valsartan and HCTZ was more effective than aliskiren and HCTZ. SBP and DBP were reduced by 15 and 11 mm Hg, respectively in the aliskiren and HCTZ group. SBP and DBP were reduced by 18 and 14 mm Hg, respectively, in the valsartan and HCTZ group.  Secondary: Blood pressure control rate was significantly higher with triple therapy compared to aliskiren and HCTZ (40.9%, P<0.001), valsartan and HCTZ (48.7%, P<0.001), and HCTZ monotherapy (20.5%, P<0.001).  At week four, a significantly greater blood pressure control rate was observed for the triple therapy group at lower doses (150-160-25 mg) compared to the respective doses of the other groups: aliskiren and valsartan and HCTZ (300-320-25 mg) group (56%) compared to aliskiren and HCTZ (36.6%, P<0.05), valsartan and HCTZ (42.2%, P<0.05), and HCTZ monotherapy (19.9%, P<0.01).  At week eight, plasma renin concentration was unchanged in the HCTZ

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>group, but was significantly increased in other groups. A significant decrease in plasma renin activity from baseline was observed in the aliskiren and HCTZ group (<math>P&lt;0.001</math>) and a significant increase was observed in the valsartan and HCTZ (<math>P&lt;0.001</math>). In the HCTZ and triple therapy groups, there was no change in plasma renin activity (both <math>P&gt;0.75</math>).</p>
<p>O'Brien et al.<sup>68</sup> (2007)</p> <p>Aliskiren 150 mg QD for 3 weeks, then HCTZ 25 mg QD was added for an additional 3 weeks (if ABPM remained <math>\geq 135/85</math> mm Hg)</p> <p>vs</p> <p>irbesartan 150 mg QD for 3 weeks, then aliskiren 75 mg QD added for 3 weeks, then aliskiren 150 mg QD added for 3 weeks</p> <p>vs</p> <p>ramipril 5 mg QD for 3 weeks, then aliskiren 75 mg QD added for 3 weeks, then aliskiren 150 mg</p>	<p>3 OL studies</p> <p>Men and women 18 to 80 years with ambulatory SBP <math>\geq 140</math> and <math>\leq 180</math> mm Hg without treatment</p>	<p>N=67</p> <p>6 to 9 weeks</p>	<p>Primary: Change in daytime systolic ABPM with combination therapy compared with monotherapy</p> <p>Secondary: Change in daytime diastolic ABPM, nighttime systolic and diastolic ABPM, daytime and nighttime heart rates, plasma renin activity</p>	<p>Primary: Aliskiren coadministered with HCTZ (<math>P=0.0007</math>) or ramipril (<math>P=0.03</math>) led to significantly greater reductions in daytime systolic ABPM compared to monotherapy. There was a trend for a reduction in daytime systolic ABPM with the addition of aliskiren to irbesartan; however, this trend was not statistically significant.</p> <p>Secondary: Aliskiren plus HCTZ significantly lowered daytime diastolic ABPM compared to aliskiren monotherapy (<math>P=0.0006</math>). Changes in nighttime systolic and diastolic ABPM followed similar trends but did not achieve statistical significance (<math>P=0.06</math> and <math>P=0.09</math>, respectively). No changes in heart rate were observed with either aliskiren regimen.</p> <p>Aliskiren added to irbesartan did not significantly change diastolic ABPM compared to irbesartan monotherapy; however, nighttime systolic and diastolic ABPM were significantly reduced (<math>P&lt;0.05</math> for all). No changes in heart rate were observed with either irbesartan regimen.</p> <p>Mean diastolic ABPM was significantly decreased with the addition of aliskiren 150 mg (<math>P&lt;0.05</math>) but not aliskiren 75 mg to ramipril monotherapy. Both aliskiren doses significantly decreased nighttime systolic and diastolic ABPM (<math>P&lt;0.05</math> for all). No changes in heart rate were observed with either ramipril regimen.</p> <p>Aliskiren alone significantly inhibited plasma renin activity by 65% (<math>P&lt;0.0001</math>), while ramipril and irbesartan monotherapy increased renin activity by 90 and 175%, respectively. When aliskiren was coadministered with HCTZ, ramipril or irbesartan, plasma renin activity remained similar to baseline levels or decreased.</p>

Conlin et al. <sup>72</sup> (2000) PREVAIL  Low-dose HCTZ plus ARB  vs  candesartan 8 to 16 mg QD, irbesartan 150 to 300 mg QD, losartan 50 to 100 mg QD, and valsartan 80 to 160 mg QD  vs  another ARB	MA  Patients with HTN	N=11,281 (43 trials)  Duration varied	Primary: Weighted average for SBP and DBP reduction with ARB monotherapy, dose titration, and with the addition of low-dose HCTZ were calculated; responder rates  Secondary: Not reported	Primary: The absolute weighted-average reductions in DBP (8.2 to 8.9 mm Hg) and SBP (10.4 to 11.8 mm Hg) for ARB monotherapy were comparable for all ARBs. Responder rates for ARB monotherapy were 48 to 55%.  Dose titration resulted in slightly greater blood pressure reductions and an increase in responder rates of 53 to 63%.  ARB and HCTZ combinations produced substantially greater reductions in SBP (16.1 to 20.6 mm Hg) and DBP (9.9 to 13.6 mm Hg) than ARB monotherapy. Responder rates for ARB and HCTZ combinations were 56 to 70%.  The authors concluded that candesartan, irbesartan, losartan, and valsartan produced comparable antihypertensive efficacy when administered at their recommended doses, a near flat dose response when titrating from starting to maximum recommended dose, and substantial potentiation of the antihypertensive effect with addition of HCTZ.  Secondary: Not reported

Baguet et al. <sup>76</sup> (2007)  Antihypertensive drugs (enalapril, ramipril, trandolapril, candesartan, irbesartan, losartan, olmesartan, telmisartan, valsartan, HCTZ, indapamide SR*, atenolol, amlodipine, lercanidipine*, manidipine*, enalapril, ramipril, trandolapril, and aliskiren)  Drugs were used as monotherapy, either at a fixed daily dosage or in increasing dosages.	MA  Patients greater than 18 years of age with mild or moderate essential HTN (SBP 140 to 179 mm Hg and/or DBP 90 to 109 mm Hg)	N=10,818  8 to 12 weeks	Primary: Weighted average reductions in SBP and DBP  Secondary: Not reported	Primary: Data did not reflect outcomes from direct, head-to-head comparative trials or formal comparisons between drugs. Diuretics (-19.2 mm Hg; 95% CI, -20.3 to -18.0), calcium channel blockers (-16.4 mm Hg; 95% CI, -17.0 to -15.8) and ACE inhibitors (-15.6 mm Hg; 95% CI, -17.6 to -13.6) produced the greatest reductions in SBP from baseline (P values not reported).  The magnitude of DBP reductions were generally similar among all drug classes; however, the greatest reductions in DBP from baseline were observed with the β-blocker, atenolol (-11.4 mm Hg; 95% CI, -12.0 to -10.9), calcium channel blockers (-11.4 mm Hg; 95% CI, -11.8 to -11.1) and diuretics (-11.1 mm Hg; 95% CI, -11.7 to -10.5) (P values were not reported).  The weighted average reduction of SBP and DBP for each drug class were as follows: Diuretics: -19.2 (95% CI, -20.3 to -18.0) and -11.1 mm Hg (95% CI, -11.7 to -10.5), respectively. β-blockers: -14.8 (95% CI, -15.9 to -13.7) and -11.4 mm Hg (95% CI, -12.0 to -10.9), respectively. Calcium channel blockers: -16.4 (95% CI, -17.0 to -15.8) and -11.4 mm Hg (95% CI, -11.8 to -11.1), respectively. ACE inhibitors: -15.6 (95% CI, -17.6 to -13.6) and -10.8 mm Hg (95% CI, -11.9 to -9.7), respectively. ARBs: -13.2 (95% CI, -13.6 to -12.9) and -10.3 mm Hg (95% CI, -10.5 to -10.1), respectively. Renin inhibitor: -13.5 (95% CI, -14.2 to -12.9) and -11.3 mm Hg (95% CI, -11.7 to -10.9), respectively.

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
metoprolol, oxprenolol*, pindolol, or propranolol)				
Hilleman et al. <sup>78</sup> (1999)  Monotherapy (atenolol, HCTZ, captopril, enalapril, lisinopril, amlodipine, diltiazem, nifedipine, verapamil)  vs  amlodipine-benazepril (fixed-dose combination)	MA (82 trials)  Patients with mild-to-moderate essential HTN	N=not reported  ≥4 weeks	Primary: Absolute change in supine DBP from baseline  Secondary: Percent of patients who achieved blood pressure control, safety	Primary: The mean absolute decrease in supine DBP ranged from 9.7 to 13.3 mm Hg with verapamil showing the greatest effect and captopril the least. When studies were weighted by sample size, amlodipine and benazepril, atenolol, lisinopril, and verapamil showed the greatest blood pressure effect.  Secondary: The average percentage of patients defined as controlled after treatment varied from 53.5 to 79.0%, with amlodipine and benazepril (74.3%) and lisinopril (79.0%) showing the highest percentage control (P=0.096).  The incidence of adverse events ranged from 12.1 to 41.8%, with lisinopril and verapamil showing the lowest incidences (12.1% and 14.1%, respectively) and nifedipine the highest incidence. Lisinopril demonstrated significantly less overall side effects compared to nifedipine (P=0.030).  Nifedipine demonstrated a higher withdrawal rate due to side effects compared to atenolol, HCTZ, enalapril, amlodipine, and diltiazem (P=0.002). Although amlodipine and benazepril had the lowest rate of withdrawals due to adverse events, lack of significant change was due to the low number of cohorts available for analysis.
Wysong et al. <sup>79</sup> (2007)  Other antihypertensive therapies (i.e., placebo, diuretics, calcium channel blockers, or renin-angiotensin system inhibitors)	MA  13 RCTs evaluating patients ≥18 years of age with HTN	N=91,561  Duration varied	Primary: All-cause mortality  Secondary: Stroke, CHD, cardiovascular death, total cardiovascular disease, adverse reactions	Primary: There was not a significant difference observed in all-cause mortality between β-blocker therapy and placebo (RR, 0.99; 95% CI, 0.88 to 1.11; P value not reported), diuretics (RR, 1.04; 95% CI, 0.91 to 1.19; P value not reported) or renin-angiotensin system inhibitors (RR, 1.10; 95% CI, 0.98 to 1.24; P value not reported). There was a significantly higher rate in all-cause mortality with β-blocker therapy compared to calcium channel blockers (RR, 1.07; 95% CI, 1.00 to 1.14; P=0.04).  Secondary: There was a significant decrease in stroke observed with β-blocker therapy

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs  β-blockers (atenolol, metoprolol, oxprenolol*, or propranolol)				<p>compared to placebo (RR, 0.80; 95% CI, 0.66 to 0.96). Also there was a significant increase in stroke with β-blocker therapy compared to calcium channel blockers (RR, 1.24; 95% CI, 1.11 to 1.40) and renin-angiotensin system inhibitors (RR, 1.30; 95% CI, 1.11 to 1.53), but there was no difference observed compared to diuretics (RR, 1.17; 95% CI, 0.65 to 2.09).</p> <p>CHD risk was not significantly different between β-blocker therapy and placebo (RR, 0.93; 95% CI, 0.81 to 1.07), diuretics (RR, 1.12; 95% CI, 0.82 to 1.54), calcium channel blockers (RR, 1.05; 95% CI, 0.96 to 1.15) or renin-angiotensin system inhibitors (RR, 0.90; 95% CI, 0.76 to 1.06).</p> <p>The risk of total cardiovascular disease was lower with β-blocker therapy compared to placebo (RR, 0.88; 95% CI, 0.79 to 0.97). The effect of β-blocker therapy on cardiovascular disease was significantly worse than that of calcium channel blockers (RR, 1.18; 95% CI, 1.08 to 1.29), but was not significantly different from that of diuretics (RR, 1.13; 95% CI, 0.99 to 1.28) or renin-angiotensin system inhibitors (RR, 1.00; 95% CI, 0.72 to 1.3).</p> <p>There was a significantly higher rate of discontinuation due to side effects with β-blocker therapy compared to diuretics (RR, 1.86; 95% CI, 1.39 to 2.50) and renin-angiotensin system inhibitors (RR, 1.41; 95% CI, 1.29 to 1.54), but there was no significant difference compared to calcium channel blockers (RR, 1.20; 95% CI, 0.71 to 2.04). Actual side effects were not reported.</p>

## IX. Cost

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of '\$' signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 9. Relative Cost of the Thiazide Diuretics**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost
Chlorothiazide	injection*, suspension, tablet*	Diuril®	\$\$	\$\$
HCTZ	capsule, tablet	N/A	N/A	\$

\*Generic is available in at least one dosage form or strength.

HCTZ=hydrochlorothiazide, N/A=Not available

## X. Conclusions

The thiazide diuretics are approved for the treatment of hypertension and edema due to renal dysfunction. They are also approved as adjunctive therapy for the management of edema associated with congestive heart failure, hepatic cirrhosis, as well as corticosteroid and estrogen therapy.<sup>1-3</sup> All of the agents are available in a generic formulation.

Guidelines recommend the use of diuretics and sodium restriction for the management of ascites due to cirrhosis. Spironolactone is recommended as first-line therapy, either as monotherapy or in combination with furosemide. Amiloride or eplerenone are alternative treatment options in patients experiencing gynecomastia with spironolactone.<sup>18</sup>

For the treatment of chronic heart failure, guidelines recommend the use of diuretics in all patients who have evidence of volume overload. Loop diuretics are generally recommended as initial therapy in patients with left

ventricular dysfunction. For those with persistent fluid retention despite treatment with a loop diuretic, a thiazide diuretic or metolazone may be added to the regimen. In patients with normal left ventricular function, either a thiazide diuretic or loop diuretic may be used as initial therapy to manage fluid overload.<sup>7,8</sup>

There are several published guidelines on the treatment of hypertension. Thiazide-type diuretics are frequently recommended as initial therapy in patients with uncomplicated hypertension.<sup>9-15</sup> According to the National Heart, Lung, and Blood Institute's Eighth Report of The Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 8), thiazide-type diuretics should be utilized first-line for most patients with hypertension, either alone or in combination with another hypertensive from a different medication class (e.g., ACE inhibitors, ARBs,  $\beta$ -blockers, calcium channel blockers).<sup>9</sup> Several guidelines consistently recommend that the selection of an antihypertensive agent be based on compelling indications for use.<sup>9-17</sup> Most patients will require more than one antihypertensive medication to achieve blood pressure goals.<sup>9-15</sup>

In clinical trials, the thiazide diuretics have been shown to effectively lower blood pressure.<sup>23-79</sup> There were no studies found in the medical literature that directly compared the efficacy and safety of the thiazide diuretics for the treatment of hypertension.

There is insufficient evidence to support that one brand thiazide diuretic is safer or more efficacious than another. Formulations without a generic alternative should be managed through the medical justification portion of the prior authorization process.

Therefore, all brand thiazide diuretics within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

## **XI. Recommendations**

No brand thiazide diuretic is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Thiazide-Like Diuretics  
AHFS Class 402824  
May 4, 2022**

**I. Overview**

The thiazide-like diuretics are approved for the treatment of edema and hypertension.<sup>1-2</sup> They inhibit sodium reabsorption in the distal convoluted tubule of the nephron. This results in an initial modest reduction in plasma volume and cardiac output. However, long-term maintenance of decreased blood pressure has been shown to be associated with partial reversal of the hemodynamic changes as plasma volume and cardiac output return to baseline. Although thiazide-like diuretics are pharmacologically similar to thiazide diuretics, there are chemical differences in the molecular structure that differentiate these agents. Indapamide may produce an independent vascular action, which results in a reduction in total peripheral resistance. Metolazone may produce diuresis in patients with glomerular filtration rates below 20 mL/minute.<sup>1-4</sup>

The thiazide-like diuretics that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. All of the agents are available in a generic formulation. This class was last reviewed in February 2020.

**Table 1. Thiazide-Like Diuretics Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
Chlorthalidone	tablet*	Thalitone®	chlorthalidone
Indapamide	tablet*	N/A	indapamide
Metolazone	tablet*	N/A	metolazone

\*Generic is available in at least one dosage form or strength.  
PDL=Preferred Drug List  
N/A=Not available

**II. Evidence-Based Medicine and Current Treatment Guidelines**

Current treatment guidelines that incorporate the use of the thiazide-like diuretics are summarized in Table 2.

**Table 2. Treatment Guidelines Using the Thiazide-Like Diuretics**

Clinical Guideline	Recommendation(s)
American Heart Association/American College of Cardiology/Heart Failure Society of America: 2022 AHA/ACC/HFSA Guideline for the Management of Heart Failure (2022) <sup>5</sup>	<p><b>Treatment of Stage A heart failure (HF)</b></p> <ul style="list-style-type: none"> <li>Hypertension should be controlled in accordance with guideline-directed medication therapy for hypertension to prevent symptomatic HF. (LoE: A)</li> <li>In patients with type 2 diabetes and either established CVD or at high cardiovascular risk, SGLT-2 inhibitors should be used to prevent hospitalizations for HF. (LoE: A)</li> <li>In the general population, healthy lifestyle habits such as regular physical activity, maintaining normal weight, healthy dietary patterns, and avoiding smoking are helpful to reduce future risk of HF. (LoE: B)</li> <li>Patients at risk of developing HF, natriuretic peptide biomarker-based screening followed by team-based care, including a cardiovascular specialist optimizing therapy, can be useful to prevent the development of LV dysfunction (systolic or diastolic) or new-onset HF. (LoE: B)</li> </ul> <p><b>Treatment of Stage B heart failure</b></p> <ul style="list-style-type: none"> <li>In patients with LVEF≤40%, ACE inhibitors should be used to prevent HF and reduce mortality. (LoE: A)</li> <li>In patients with a recent or remote history of MI or ACS, statins should be used to prevent symptomatic HF and adverse cardiovascular events. (LoE: A)</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• In patients with a recent MI and LVEF ≤40% who are intolerant to ACE inhibitors, ARB should be used to prevent symptomatic HF and reduce mortality. (LoE: B)</li> <li>• In patients with a recent or remote history of MI or ACS and LVEF ≤40%, evidence-based beta blockers should be used to reduce mortality. (LoE: B)</li> <li>• In patients who are at least 40 days post-MI with LVEF ≤30% and NYHA class I symptoms while receiving guideline-directed medication therapy and have reasonable expectation of meaningful survival for greater than one year, an implantable cardioverter-defibrillator is recommended for primary prevention of sudden cardiac death to reduce total mortality. (LoE: B)</li> <li>• In patients with LVEF ≤40%, beta blockers should be used to prevent symptomatic HF. (LoE: C)</li> <li>• In patients with LVEF ≤50%, thiazolidinediones should not be used because they increase the risk of HF, including hospitalizations. (LoE: B)</li> <li>• In patients with LVEF ≤50%, nondihydropyridine calcium channel blockers with negative inotropic effects may be harmful. (LoE: C)</li> </ul> <p><u>Treatment for Stage C Heart Failure with Reduced Ejection Fraction (HFrEF)</u></p> <ul style="list-style-type: none"> <li>• For patients with stage C HF, avoiding excessive sodium intake is reasonable to reduce congestive symptoms. (LoE: C)</li> <li>• In patients with HF who have fluid retention, diuretics are recommended to relieve congestion, improve symptoms, and prevent worsening HF. (LoE: B)</li> <li>• For patients with HF and congestive symptoms, addition of a thiazide (e.g., metolazone) to treatment with a loop diuretic should be reserved for patients who do not respond to moderate or high dose loop diuretics to minimize electrolyte abnormalities. (LoE: B)</li> <li>• In patients with HFrEF and NYHA class II to III symptoms, the use of an ARNI is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, the use of an ACE inhibitor is beneficial to reduce morbidity and mortality when the use of an ARNI is not feasible. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, who are intolerant to an ACE inhibitor because of cough or angioedema, and when the use of an ARNI is not feasible, the use of an ARB is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with chronic symptomatic HFrEF NYHA class II or III who tolerate an ACE inhibitor or ARB, replacement by an ARNI is recommended to further reduce morbidity and mortality. (LoE: B)</li> <li>• ARNIs should not be administered concomitantly with ACE inhibitors or within 36 hours of the last dose of an ACE inhibitor. (LoE: B)</li> <li>• ARNI or ACE inhibitors should not be administered in patients with a history of angioedema. (LoE: C)</li> <li>• In patients with HFrEF, with current or previous symptoms, use of one of the three β-blockers proven to reduce mortality (e.g., bisoprolol, carvedilol, sustained-release metoprolol succinate) is recommended to reduce mortality and hospitalizations. (LoE: A)</li> <li>• In patients with HFrEF and NYHA class II to IV symptoms, a mineralocorticoid receptor antagonist (spironolactone or eplerenone) is recommended to reduce morbidity and mortality, if eGFR is &gt;30 mL/min/1.73 m<sup>2</sup> and serum potassium is &lt;5.0 mEq/L. Careful monitoring of potassium, renal function, and diuretic dosing should be performed at initiation and closely followed thereafter to minimize risk of hyperkalemia and renal insufficiency. (LoE: A)</li> <li>• In patients taking a mineralocorticoid receptor antagonist whose serum potassium cannot be maintained at &lt;5.5 mEq/L, mineralocorticoid receptor antagonist should be discontinued to avoid life threatening hyperkalemia. (LoE: B)</li> <li>• In patients with symptomatic chronic HFrEF, SGLT-2 an inhibitor is</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>recommended to reduce hospitalization for HF and cardiovascular mortality, irrespective of the presence of type 2 diabetes. (LoE: A)</p> <ul style="list-style-type: none"> <li>• The combination of hydralazine and isosorbide dinitrate is recommended to improve symptoms and reduce morbidity and mortality for patients self-identified as African Americans with NYHA class III to IV HFrEF receiving optimal therapy. (LoE: A)</li> <li>• In patients with current or previous symptomatic HFrEF who cannot be given first-line agents, such as an ARNI, ACE inhibitor or ARB because of drug intolerance or renal insufficiency, a combination of hydralazine and isosorbide dinitrate might be considered to reduce morbidity and mortality. (LoE: C)</li> <li>• In patients with HF class II to IV symptoms, omega-3 polyunsaturated fatty acid supplementation may be reasonable to use as adjunctive therapy to reduce mortality and cardiovascular hospitalizations. (LoE: B)</li> <li>• In patients with chronic HFrEF without specific indication (e.g., venous thromboembolism, atrial fibrillation, a previous thromboembolic event, or a cardioembolic source, anticoagulation is not recommended. (LoE: B)</li> <li>• Dihydropyridine and non-dihydropyridine calcium channel blockers are not recommended for patients with HFrEF. (LoE: A)</li> <li>• In patients with HFrEF, vitamins, nutritional supplements, and hormonal therapy are not recommended other than to correct specific deficiencies. (LoE: B)</li> <li>• In patients with HFrEF, class IC antiarrhythmic medication and dronedarone may increase risk of mortality. (LoE: A)</li> <li>• In patients with HFrEF, thiazolidinediones increase the risk of worsening HF symptoms and hospitalizations. (LoE: A)</li> <li>• In patients with type 2 diabetes and high cardiovascular risk, the DPP-4 inhibitors, saxagliptin and alogliptin, increase the risk of HF hospitalization and should be avoided in patients with HF. (LoE: B)</li> <li>• In patients with HFrEF, nonsteroidal anti-inflammatory drugs worsen HF symptoms and should be avoided or withdrawn whenever possible. (LoE: B)</li> <li>• For patients with symptomatic (NYHA class II to III) stable chronic HFrEF (LVEF <math>\leq</math>35%) who are receiving guideline-directed medical therapy, including a maximally tolerated dose of a beta blocker, and who are in sinus rhythm with a heart rate of <math>\geq</math>70 beats per minute at rest, ivabradine can be beneficial to reduce HF hospitalizations and cardiovascular death. (LoE: B)</li> <li>• In patients with symptomatic HFrEF despite guideline-directed medical therapy or who are unable to tolerate guideline-directed medical therapy, digoxin might be considered to decrease hospitalizations for HF. (LoE: B)</li> <li>• In select high-risk patients with HFrEF and recent worsening of HF already on guideline-directed medical therapy, an oral soluble guanylate cyclase stimulator (vericiguat) may be considered to reduce HF hospitalization and cardiovascular death. (LoE: B)</li> </ul> <p><b>Pharmacological treatment for Stage C HF with mildly reduced EF and improved EF</b></p> <ul style="list-style-type: none"> <li>• In patients with HF with mildly reduced EF, SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• Among patients with current or previous symptomatic HF with mildly reduced EF (LVEF, 41 to 49%), use of evidence-based beta blockers for HFrEF, ARNI, ACE inhibitor or ARB, and mineralocorticoid receptor antagonists may be considered to reduce the risk of HF hospitalization and cardiovascular mortality, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• In patients with HF with improved EF after treatment, guideline-directed medical therapy should be continued to prevent relapse of HF and LV dysfunction, even in patients who may become asymptomatic. (LoE: B)</li> </ul> <p><b>Pharmacological treatment for Stage C HF with preserved EF (HFpEF)</b></p>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• Patients with hypertension and HFpEF should have medication titrated to attain blood pressure targets in accordance with published clinical practice guidelines to prevent morbidity. (LoE: C)</li> <li>• SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• In patients with HFpEF, the use of a mineralocorticoid receptor antagonist, ARB, or ARNI may be considered to decrease hospitalizations, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• Routine use of nitrates or phosphodiesterase-5 inhibitors to increase activity or quality of life in patients with HFpEF is ineffective. (LoE: B)</li> </ul> <p><u>Treatment of Stage D (advanced/refractory) HF</u></p> <ul style="list-style-type: none"> <li>• For patients with advanced HF and hyponatremia, the benefit of fluid restriction to reduce congestive symptoms is uncertain. (LoE: C)</li> <li>• Continuous intravenous inotropic support is reasonable as “bridge therapy” in patients with HF (Stage D) refractory to guideline-directed medical therapy and device therapy who are eligible for and awaiting mechanical circulatory support or cardiac transplantation. (LoE: B)</li> <li>• In select patients with HF Stage D, despite optimal guideline-directed medical therapy and device therapy who are ineligible for either mechanical circulatory support or cardiac transplantation, continuous intravenous inotropic support may be considered as palliative therapy for symptom control and improvement in functional status. (LoE: B)</li> <li>• Long-term use of either continuous or intermittent, intravenous inotropic agents, for reasons other than palliative care or as a bridge to advanced therapies, is potentially harmful. (LoE: B)</li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure (2021)</b><sup>6</sup></p>	<p><u>Pharmacological treatments indicated in patients with (NYHA Class II-IV) heart failure with reduced ejection fraction</u></p> <ul style="list-style-type: none"> <li>• An ACE inhibitor is recommended, in addition to a <math>\beta</math>-blocker, for symptomatic patients with HFrEF to reduce the risk of HF hospitalization and death.</li> <li>• A mineralocorticoid receptor antagonist (MRA) is recommended for patients with HFrEF, who remain symptomatic despite treatment with an ACE inhibitor and a <math>\beta</math>-blocker, to reduce the risk of HF hospitalization and death.</li> <li>• Dapagliflozin or empagliflozin are recommended for patients with HFrEF to reduce the risk of HF hospitalization and death. Dapagliflozin or empagliflozin are recommended, in addition to optimal medical therapy with an ACE-I/ARNI, a <math>\beta</math>-blocker and an MRA, for patients with HFrEF regardless of diabetes status.</li> <li>• Sacubitril-valsartan is recommended as a replacement for an ACE inhibitor to further reduce the risk of HF hospitalization and death in ambulatory patients with HFrEF who remain symptomatic despite optimal treatment with an ACE inhibitor, a <math>\beta</math>-blocker, and a mineralocorticoid receptor antagonist.</li> <li>• Diuretics are recommended in order to improve symptoms and exercise capacity in patients with signs and/or symptoms of congestion.</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization or cardiovascular death in symptomatic patients with LVEF <math>\leq</math>35%, in sinus rhythm and a resting heart rate <math>\geq</math>70 bpm despite treatment with an evidence-based dose of <math>\beta</math>-blocker (or maximum tolerated dose below that), ACE inhibitor (or ARB), and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients with LVEF <math>\leq</math>35%, in sinus rhythm and a resting heart rate <math>\geq</math>70 bpm who are unable to tolerate or have contraindications for a <math>\beta</math>-blocker. Patients should also receive an ACE inhibitor (or ARB) and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• An ARB is recommended to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients unable to tolerate an ACE inhibitor</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>(patients should also receive a <math>\beta</math>-blocker and mineralocorticoid receptor antagonist).</p> <ul style="list-style-type: none"> <li>• An ARB may be considered to reduce the risk of HF hospitalization and death in patients who are symptomatic despite treatment with a <math>\beta</math>-blocker who are unable to tolerate a mineralocorticoid receptor antagonist.</li> <li>• Vericiguat may be considered in patients in NYHA class II-IV who have had worsening HF despite treatment with an ACE-I (or ARNI), a <math>\beta</math>-blocker and an MRA to reduce the risk of CV mortality or HF hospitalization.</li> <li>• Hydralazine and isosorbide dinitrate should be considered in self-identified black patients with LVEF <math>\leq 35\%</math> or with an LVEF <math>&lt; 45\%</math> combined with a dilated LV in NYHA Class III-IV despite treatment with an ACE-I a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist to reduce the risk of HF hospitalization and death.</li> <li>• Hydralazine and isosorbide dinitrate may be considered in symptomatic patients with HF<sub>r</sub>EF who can tolerate neither an ACE inhibitor nor an ARB (or they are contraindicated) to reduce the risk of death.</li> <li>• Digoxin is a treatment with less-certain benefits and may be considered in symptomatic patients in sinus rhythm despite treatment with an ACE inhibitor (or ARB), a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist, to reduce the risk of hospitalization (both all-cause and HF-hospitalizations).</li> </ul> <p><u>Recommendations for treatment of patients with (NYHA class II-IV) heart failure with mildly reduced ejection fraction (HF<sub>mr</sub>EF)</u></p> <ul style="list-style-type: none"> <li>• Diuretics are recommended in patients with congestion and HF<sub>mr</sub>EF in order to alleviate symptoms and signs.</li> <li>• An ACE inhibitor may be considered for patients with HF<sub>mr</sub>EF to reduce the risk of HF hospitalization and death.</li> <li>• An ARB may be considered for patients with HF<sub>mr</sub>EF to reduce the risk of HF hospitalization and death.</li> <li>• A <math>\beta</math>-blocker may be considered for patients with HF<sub>mr</sub>EF to reduce the risk of HF hospitalization and death.</li> <li>• An MRA may be considered for patients with HF<sub>mr</sub>EF to reduce the risk of HF hospitalization and death.</li> <li>• Sacubitril/valsartan may be considered for patients with HF<sub>mr</sub>EF to reduce the risk of HF hospitalization and death.</li> </ul> <p><u>Recommendations for treatment of patients with heart failure with preserved ejection fraction (HF<sub>p</sub>EF)</u></p> <ul style="list-style-type: none"> <li>• It is recommended to screen patients with HF<sub>p</sub>EF for both cardiovascular and noncardiovascular comorbidities, which, if present, should be treated provided safe and effective interventions exist to improve symptoms, well-being and/or prognosis.</li> <li>• Diuretics are recommended in congested patients with HF<sub>p</sub>EF in order to alleviate symptoms and signs.</li> </ul> <p><u>Recommendations for the primary prevention of heart failure in patients with risk factors for its development</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension is recommended to prevent or delay the onset of HF and prolong life.</li> <li>• Treatment with statins is recommended in patients at high risk of CV disease or with CV disease in order to prevent or delay the onset of HF, and to prevent HF hospitalizations.</li> <li>• SGLT2 inhibitors (canagliflozin, dapagliflozin, empagliflozin, ertugliflozin, sotagliflozin) are recommended in patients with diabetes at high risk of CV disease or with CV disease in order to prevent HF hospitalizations.</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• Counselling against sedentary habit, obesity, cigarette smoking, and alcohol abuse is recommended to prevent or delay the onset of HF.</li> </ul> <p><u>Recommendations for the initial management of patients with acute heart failure – pharmacotherapy</u></p> <ul style="list-style-type: none"> <li>• Intravenous loop diuretics are recommended for all patients with acute HF admitted with signs/symptoms of fluid overload to improve symptoms. It is recommended to regularly monitor symptoms, urine output, renal function and electrolytes during use of intravenous diuretics.</li> <li>• Combination of a loop diuretic with thiazide type diuretic should be considered in patients with resistant oedema who do not respond to an increase in loop diuretic doses.</li> <li>• In patients with acute HF and SBP &gt;110 mmHg, intravenous vasodilators may be considered as initial therapy to improve symptoms and reduce congestion.</li> <li>• Inotropic agents may be considered in patients with SBP &lt;90 mmHg and evidence of hypoperfusion who do not respond to standard treatment, including fluid challenge, to improve peripheral perfusion and maintain end-organ function.</li> <li>• Inotropic agents are not recommended routinely, due to safety concerns, unless the patient has symptomatic hypotension and evidence of hypoperfusion.</li> <li>• A vasopressor, preferably norepinephrine, may be considered in patients with cardiogenic shock to increase blood pressure and vital organ perfusion.</li> <li>• Thromboembolism prophylaxis (e.g. with LMWH) is recommended in patients not already anticoagulated and with no contraindication to anticoagulation, to reduce the risk of deep venous thrombosis and pulmonary embolism.</li> <li>• Routine use of opiates is not recommended, unless in selected patients with severe/intractable pain or anxiety.</li> </ul>
<p>Eighth Joint National Committee (JNC 8): <b>2014 Evidence-based Guideline for the Management of High Blood Pressure in Adults (2014)</b><sup>7</sup></p>	<ul style="list-style-type: none"> <li>• Pharmacologic treatment should be initiated in patients ≥60 years of age to lower blood pressure at systolic blood pressure ≥150 mm Hg or diastolic blood pressure ≥90 mm Hg and to a goal systolic blood pressure &lt;150 mm Hg and goal diastolic blood pressure &lt;90 mm Hg. Adjustment of treatment is not necessary if treatment results in lower blood pressure and treatment is well tolerated and without adverse effects on health or quality of life.</li> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at diastolic blood pressure ≥90 mm Hg to a goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥150 mm Hg to a goal diastolic blood pressure &lt;140 mm Hg.</li> <li>• For patients ≥18 years of age with chronic kidney disease or diabetes, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥140 mm Hg or diastolic blood pressure ≥90 mm Hg and to a goal systolic blood pressure &lt;140 mm Hg and goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• Initial antihypertensive treatment for the general nonblack population, including those with diabetes, should include thiazide-type diuretic, calcium channel blocker (CCB), ACE inhibitor, or ARB.</li> <li>• Initial antihypertensive treatment for the general black population, including those with diabetes, should include thiazide-type diuretic or CCB.</li> <li>• For patients ≥18 years of age with chronic kidney disease regardless of race or diabetes status, initial (or add-on) treatment should include an ACE inhibitor or ARB to improve kidney outcomes.</li> <li>• The main goal of antihypertensive treatment is to attain and maintain goal blood pressure.</li> <li>• If goal blood pressure is not attained within a month of treatment, the dose of the initial drug should be increased or second drug from the thiazide-type diuretic,</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>CCB, ACE inhibitor, or ARB classes should be added.</p> <ul style="list-style-type: none"> <li>• If goal is not achieved with two drugs, a third drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• An ACE inhibitor and ARB should not be used together.</li> <li>• Antihypertensive classes can be used if the patient is unable to achieve goal blood pressure with three agents or had a contraindication to a preferred class.</li> <li>• If blood pressure is not able to be achieved or in complicated patients, referral to a hypertension specialist may be indicated.</li> </ul>
<p>International Society of Hypertension: <b>Global Hypertension Practice Guidelines (2020)</b><sup>8</sup></p>	<p><b>Lifestyle modifications</b></p> <ul style="list-style-type: none"> <li>• Lifestyle modification is the first line of antihypertensive treatment.</li> <li>• Salt reduction: Reduce salt added when preparing foods, and at the table. Avoid or limit consumption of high salt foods such as soy sauce, fast foods and processed food including breads and cereals high in salt.</li> <li>• Healthy diet: Eating a diet that is rich in whole grains, fruits, vegetables, polyunsaturated fats and dairy products and reducing food high in sugar, saturated fat and trans fats, such as the DASH diet.</li> <li>• Healthy drinks: Moderate consumption of coffee, green and black tea. Other beverages that can be beneficial include karkadé (hibiscus) tea, pomegranate juice, beetroot juice and cocoa.</li> <li>• Moderation of alcohol consumption: The recommended daily limit for alcohol consumptions is 2 standard drinks for men and 1.5 for women (10 g alcohol/standard drink). Avoid binge drinking.</li> <li>• Weight reduction: Body weight control is indicated to avoid obesity. Particularly abdominal obesity should be managed. Ethnic-specific cut-offs for BMI and waist circumference should be used. Alternatively, a waist-to-height ratio &lt;0.5 is recommended for all populations.</li> <li>• Smoking cessation: Smoking is a major risk factor for cardiovascular disease (CVD), COPD and cancer. Smoking cessation and referral to smoking cessation programs are advised.</li> <li>• Regular physical activity: Studies suggest that regular aerobic and resistance exercise may be beneficial for both the prevention and treatment of hypertension. Moderate intensity aerobic exercise (walking, jogging, cycling, yoga, or swimming) for 30 minutes on five to seven days per week Strength training also can help reduce blood pressure. Performance of resistance/strength exercises on two to three days per week.</li> <li>• Reduce stress and induce mindfulness: Stress should be reduced and mindfulness or meditation introduced into the daily routine.</li> <li>• Reduce exposure to air pollution and cold temperature: Evidence from studies support a negative effect of air pollution on blood pressure in the long-term.</li> </ul> <p><b>Pharmacological Treatment</b></p> <ul style="list-style-type: none"> <li>• Ideal characteristics of drug treatment <ul style="list-style-type: none"> <li>○ Treatments should be evidence-based in relation to morbidity/mortality prevention.</li> <li>○ Use a once-daily regimen which provides 24-hour blood pressure control.</li> <li>○ Treatment should be affordable and/or cost-effective relative to other agents.</li> <li>○ Treatments should be well-tolerated.</li> <li>○ Evidence of benefits of use of the medication in populations to which it is to be applied.</li> </ul> </li> <li>• General scheme for drug treatment <ul style="list-style-type: none"> <li>○ Lifestyle modification is the first line of antihypertensive treatment.</li> <li>○ Grade 1 hypertension (BP 140 to 159/ 90 to 99): Immediate drug treatment in high-risk patients or those with CVD, chronic kidney disease (CKD), diabetes mellitus (DM), or hypertension-mediated organ damage</li> </ul> </li> </ul>

Clinical Guideline	Recommendation(s)
	<p>(HMOD). Drug treatment after three to six months of lifestyle intervention if BP still not controlled in low to moderate risk patients.</p> <ul style="list-style-type: none"> <li>○ Grade 2 hypertension (BP <math>\geq</math>160/100): Immediate drug treatment in all patients.</li> <li>● Core drug-treatment strategy <ul style="list-style-type: none"> <li>○ Step 1: Dual low-dose combination (ACE inhibitor or ARB plus dihydropyridine-calcium channel blockers (DHP-CCB)); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance; consider ACE/ARB plus DHP-CCB or DHP-CCB plus thiazide-like diuretics in black patients.</li> <li>○ Step 2: Dual full-dose combination (ACE inhibitor or ARB plus DHP-CCB); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance.</li> <li>○ Step 3: Triple combination (ACE/ARB plus DHP-CCB plus thiazide-like diuretic).</li> <li>○ Step 4, resistant hypertension: triple combination plus spironolactone or other drug, alternatives include amiloride, doxazosin, eplerenone, clonidine, or <math>\beta</math>-blocker. Caution with spironolactone or other potassium sparing diuretics when estimated GFR <math>&lt;</math>45 mL/min/1.73m<sup>2</sup> or K<sup>+</sup> <math>&gt;</math>4.5 mmol/L.</li> <li>○ Consider <math>\beta</math>-blockers at any treatment step when there is a specific indications for their use, e.g., heart failure, angina, post-MI, atrial fibrillation, or younger women planning pregnancy or pregnant.</li> </ul> </li> </ul>
<p>Hypertension Canada: <b>2020 Guidelines for the Prevention, Diagnosis, Risk Assessment, and Treatment of Hypertension in Adults and Children (2020)</b><sup>9</sup></p>	<p><u>Indications for drug therapy for adults with hypertension without compelling indications for specific agents</u></p> <ul style="list-style-type: none"> <li>● Antihypertensive therapy should be prescribed for average diastolic blood pressure (DBP) measurements of <math>\geq</math>100 mmHg or average systolic blood pressure (SBP) measurements of <math>\geq</math>160 mmHg in patients without macrovascular target organ damage or other cardiovascular risk factors.</li> <li>● Antihypertensive therapy should be strongly considered for average DPB readings <math>\geq</math>90 mmHg or for average SBP readings <math>\geq</math>140 mmHg in the presence of macrovascular target organ damage or other independent cardiovascular risk factors.</li> <li>● For high-risk patients, aged 50 years or older, with SBP levels <math>\geq</math>130 mmHg, intensive management to target a SBP <math>&lt;</math>120 mmHg should be considered. Patient selection for intensive management is recommended and caution should be taken in certain high-risk groups.</li> </ul> <p><u>Indications for drug therapy for adults with diastolic and with or without systolic hypertension</u></p> <ul style="list-style-type: none"> <li>● Initial therapy should be with either monotherapy or single pill combination (SPC). <ul style="list-style-type: none"> <li>○ Recommended monotherapy choices are: <ul style="list-style-type: none"> <li>▪ A thiazide/thiazide-like diuretic, with longer-acting diuretics preferred;</li> <li>▪ A <math>\beta</math>-blocker (in patients <math>&lt;</math>60 years of age);</li> <li>▪ An angiotensin-converting enzyme (ACE) inhibitor (in nonblack patients);</li> <li>▪ An angiotensin receptor blocker (ARB); or</li> <li>▪ A long-acting calcium channel blocker (CCB).</li> </ul> </li> <li>○ Recommended SPC choices are those in which an ACE inhibitor is combined with a CCB, ARB with a CCB, or ACE inhibitor or ARB with a diuretic.</li> <li>○ Hypokalemia should be avoided in patients treated with thiazide/thiazide-like</li> </ul> </li> </ul>

Clinical Guideline	Recommendation(s)
	<p data-bbox="581 205 821 233">diuretic monotherapy.</p> <ul data-bbox="488 237 1406 699" style="list-style-type: none"> <li data-bbox="488 237 1406 415">• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line choices. Useful choices include a thiazide/thiazide-like diuretic or CCB with either: ACE inhibitor, ARB, or <math>\beta</math>-blocker. Caution should be exercised in combining a nondihydropyridine CCB and a <math>\beta</math>-blocker. The combination of an ACE inhibitor and an ARB is not recommended.</li> <li data-bbox="488 420 1406 478">• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other antihypertensive drugs may be added.</li> <li data-bbox="488 483 1406 510">• Possible reasons for poor response to therapy should be considered.</li> <li data-bbox="488 514 1406 699">• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated hypertension; <math>\beta</math>-blockers are not recommended as first-line therapy for uncomplicated hypertension in patients <math>\geq 60</math> years of age; and ACE inhibitors are not recommended as first-line therapy for uncomplicated hypertension in black patients. Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• Initial therapy should include a <math>\beta</math>-blocker as well as an ACE inhibitor.</li> <li>• An ARB can be used if the patient is intolerant of an ACE inhibitor.</li> <li>• CCBs may be used in patients after myocardial infarction when <math>\beta</math>-blockers are contraindicated or not effective. Nondihydropyridine CCBs should not be used when there is heart failure, evidenced by pulmonary congestion on examination or radiography.</li> </ul> <p><b>Treatment of hypertension in association with heart failure</b></p> <ul style="list-style-type: none"> <li>• In patients with systolic dysfunction (ejection fraction &lt;40%), ACE inhibitors and <math>\beta</math>-blockers are recommended for initial therapy. Aldosterone antagonists (mineralocorticoid receptor antagonists) may be combined in treatment for patients with a recent cardiovascular hospitalization, acute myocardial infarction, elevated B-type natriuretic peptide or N-terminal pro-B-type natriuretic peptide level, or New York Heart Association (NYHA) Class II-IV symptoms. Careful monitoring for hyperkalemia is recommended when combining an aldosterone antagonist with ACE inhibitor or ARB treatment. Other diuretics are recommended as additional therapy if needed. Beyond considerations of BP control, doses of ACE inhibitors or ARBs should be titrated to those reported to be effective in trials unless adverse effects become manifest.</li> <li>• An ARB is recommended if ACE inhibitors are not tolerated.</li> <li>• A combination of hydralazine and isosorbide dinitrate is recommended if ACE inhibitors and ARBs are contraindicated or not tolerated.</li> <li>• For hypertensive patients whose BP is not controlled, an ARB may be combined with an ACE inhibitor and other antihypertensive drug treatment. Careful monitoring should be used if combining an ACE inhibitor and an ARB because of potential adverse effects such as hypotension, hyperkalemia, and worsening renal function. Additional therapies may also include dihydropyridine CCBs.</li> <li>• An angiotensin receptor-neprilysin inhibitor (ARNI) should be used in place of an ACE inhibitor or ARB for patients with HFrEF (&lt;40%) who remain symptomatic despite treatment with appropriate dose of guideline directed HF therapy. Eligible patients must have a serum potassium &lt;5.2 mmol/L, an eGFR <math>\leq</math>30 mL/min/1.73m<sup>2</sup> and close surveillance of serum potassium and creatinine.</li> </ul> <p><b>Treatment of hypertension in association with stroke</b></p> <ul style="list-style-type: none"> <li>• BP management in acute ischemic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> <li>• BP management after acute ischemic stroke <ul style="list-style-type: none"> <li>○ Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack.</li> <li>○ After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently &lt;140/90 mmHg.</li> <li>○ Treatment with an ACE inhibitor and thiazide/thiazide-like diuretic combination is preferred.</li> <li>○ For patients with stroke, the combination of an ACE inhibitor and ARB is not recommended.</li> </ul> </li> <li>• BP management in hemorrhagic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> </ul> <p><b>Treatment of hypertension in association with LVH</b></p> <ul style="list-style-type: none"> <li>• Hypertensive patients with LVH should be treated with antihypertensive therapy to decrease the rate of subsequent cardiovascular events.</li> <li>• The choice of initial therapy can be influenced by the presence of LVH. Initial therapy can be drug treatment using ACE inhibitors, ARBs, long-acting CCBs, or thiazide/thiazide-like diuretics. Direct arterial vasodilators such as hydralazine or minoxidil should not be used.</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><u>Treatment of hypertension in association with nondiabetic chronic kidney disease</u></p> <ul style="list-style-type: none"> <li>• Individualize BP targets in patients with chronic kidney disease. Consider intensive targets (SBP &lt;120 mmHg) in appropriate patients.</li> <li>• For patients with hypertension and proteinuric chronic kidney disease (urinary protein &gt;150 mg per 24 hours or albumin to creatinine ratio &gt;30 mg/mmol), initial therapy should be an ACE inhibitor or an ARB if there is intolerance to ACE inhibitors.</li> <li>• In most cases, combination therapy with other antihypertensive agents might be needed to reach target BP levels.</li> <li>• The combination of an ACE inhibitor and ARB is not recommended for patients with nonproteinuric chronic kidney disease.</li> </ul> <p><u>Treatment of hypertension in association with renovascular disease</u></p> <ul style="list-style-type: none"> <li>• Patients with hypertension attributable to atherosclerotic renal artery stenosis should be primarily medically managed because renal angioplasty and stenting offers no benefit over optimal medical therapy alone.</li> <li>• Renal artery angioplasty and stenting for atherosclerotic hemodynamically significant renal artery stenosis could be considered for patients with uncontrolled hypertension resistant to maximally tolerated pharmacotherapy, progressive renal function loss, and acute pulmonary edema.</li> <li>• Patients with confirmed renal fibromuscular dysplasia (FMD) should be referred to a hypertension specialist.</li> <li>• Renal artery angioplasty without stenting is recommended for treatment of FMD-related renal artery stenosis. Stenting is not recommended unless needed because of a periprocedural dissection. Surgical revascularization should be considered in cases of complex lesions less amendable to angioplasty, stenosis associated with complex aneurysm, and restenosis despite two unsuccessful attempts of angioplasty.</li> </ul> <p><u>Treatment of hypertension in association with diabetes mellitus</u></p> <ul style="list-style-type: none"> <li>• Persons with diabetes mellitus should be treated to attain SBP of &lt;130 mmHg and DBP of &lt;80 mmHg.</li> <li>• For persons with cardiovascular or kidney disease, including microalbuminuria, or with cardiovascular risk factors in addition to diabetes and hypertension, an ACE inhibitor or an ARB is recommended as initial therapy.</li> <li>• For persons with diabetes and hypertension not included in other guidelines in this section, appropriate choices include (in alphabetical order): ACE inhibitors, ARBs, dihydropyridine CCBs, and thiazide/thiazide-like diuretics.</li> <li>• If target BP levels are not achieved with standard-dose monotherapy, additional antihypertensive therapy should be used. For persons in whom combination therapy with an ACE inhibitor is being considered, a dihydropyridine CCB is preferable to a thiazide/thiazide-like diuretic.</li> </ul> <p><u>Resistant hypertension</u></p> <ul style="list-style-type: none"> <li>• Resistant hypertension is defined as BP above target despite three or more BP-lowering drugs at optimal doses preferably including a diuretic (and usually a renin-angiotensin-aldosterone system blocker and a CCB).</li> <li>• Accurate office and out-of-office BP measurement is essential.</li> <li>• Other reasons for apparent resistant hypertension should be eliminated before diagnosing true resistant hypertension, including nonadherence, white coat effect, and secondary hypertension.</li> <li>• Pharmacotherapy with the additional use of spironolactone, bisoprolol, doxazosin, amiloride, eplerenone, or clonidine with the baseline regimen decreases BP significantly, with the greatest BP-lowering shown with spironolactone.</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• Patients with resistant hypertension should be referred to providers with expertise in diagnosis and management of hypertension.</li> </ul> <p><u>Hypertension and pediatrics</u></p> <ul style="list-style-type: none"> <li>• BP should be measured regularly in children three years of age or older; the auscultatory method is the gold-standard at present.</li> <li>• Initial therapy should be monotherapy, with an ACE inhibitor or ARB (not first-line in black children), or a long-acting dihydropyridine CCB.</li> <li>• The treatment goal is systolic and diastolic office BP and/or ABPM &lt; 95th percentile or &lt;90th percentile in children with risk factors or target organ damage.</li> <li>• Complex cases should be referred to an expert in pediatric hypertension.</li> </ul> <p><u>Hypertension and pregnancy</u></p> <ul style="list-style-type: none"> <li>• Up to 7% of pregnancies are complicated by a hypertensive disorder of pregnancy, and approximately 5% of women will have chronic hypertension when they become pregnant.</li> <li>• The prevalence of hypertension in pregnancy is expected to increase with women becoming pregnant later in their reproductive years and the increasing prevalence of cardiovascular comorbidities such as increased preconception body mass index and maternal diabetes.</li> <li>• The possibility of pregnancy should be considered when managing women with hypertension who are of reproductive age.</li> <li>• Preconception counselling should be offered to all women with hypertension who are considering pregnancy.</li> <li>• ACE inhibitor and ARB therapy should be avoided before conception and during pregnancy unless there is a compelling indication for their use (i.e., proteinuric kidney disease).</li> <li>• Hypertension during pregnancy can increase the risk of adverse maternal and fetal outcomes, including an increased risk of preeclampsia, placental abruption, prematurity, small for gestational age infants, stillbirth, and maternal renal and retinal injury, thus generally requires involvement of an interdisciplinary team including obstetrical care providers.</li> <li>• Antihypertensive therapy is recommended for average SBP measurements of <math>\geq 140</math> mmHg or DBP measurements of <math>\geq 90</math> mmHg in pregnant women with chronic hypertension, gestational hypertension, or preeclampsia. Initial antihypertensive therapy should be monotherapy from the following first-line drugs: oral labetalol, oral methyldopa, long-acting oral nifedipine, or other oral <math>\beta</math>-blockers (acebutolol, metoprolol, pindolol, and propranolol). Other antihypertensive drugs can be considered as second-line drugs including: clonidine, hydralazine, and thiazide diuretics.</li> <li>• Women with severe hypertension with SBP <math>\geq 160</math> mmHg or DBP <math>\geq 110</math> mmHg in pregnancy or postpartum require urgent antihypertensive therapy because it is considered an obstetrical emergency.</li> <li>• Antihypertensive drugs used in breastfeeding women include: labetalol, methyldopa, long-acting nifedipine, enalapril, or captopril.</li> </ul>
<p>European Society of Hypertension/ European Society of Cardiology: <b>2018 Guidelines for the management of arterial hypertension (2018)</b><sup>10</sup></p>	<p><u>Treatment strategies and choice of antihypertensive drugs</u></p> <ul style="list-style-type: none"> <li>• Diuretics (including thiazides, chlorthalidone, and indapamide), <math>\beta</math>-blockers, calcium channel blocker (CCB), angiotensin-converting enzyme (ACE) inhibitors, and angiotensin receptor blockers (ARBs) are all suitable for the initiation and maintenance of antihypertensive treatment, either as monotherapy or in some combinations.</li> <li>• Some agents should be considered as the preferential choice in specific conditions because used in trials in those conditions or because of greater effectiveness in specific types of organ damage. Preferred combinations should comprise a renin-angiotensin system (RAS) blocker (either an ACE inhibitor or an ARB) with a</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>CCB or diuretic.</p> <ul style="list-style-type: none"> <li>• It is recommended that beta-blockers are combined with any of the other major drug classes when there are specific clinical situations, e.g. angina, post-myocardial infarction, heart failure, or heart rate control.</li> <li>• Initiation of antihypertensive therapy with a two-drug combination may be considered in patients with markedly high baseline blood pressure (BP) or at high cardiovascular (CV) risk.</li> <li>• The combination of two antagonists of the RAS is not recommended and should be discouraged.</li> <li>• Other drug combinations should be considered and probably are beneficial in proportion to the extent of BP reduction. However, combinations that have been successfully used in trials may be preferable.</li> <li>• Combinations of two antihypertensive drugs at fixed doses in a single tablet may be recommended and favored, because reducing the number of daily pills improves adherence, which is low in patients with hypertension. Exceptions are frail older patients and those at low risk and with grade one hypertension (particularly if systolic BP is &lt;150 mmHg).</li> <li>• It is recommended that if BP is not controlled with a three-drug combination, treatment should be increased by the addition of spironolactone or, if not tolerated, other diuretics such as amiloride or higher doses of other diuretics, a beta-blocker, or an alpha-blocker.</li> </ul> <p><u>Treatment strategies in white-coat and masked hypertension</u></p> <ul style="list-style-type: none"> <li>• In white-coat hypertensives without additional risk factors, therapeutic intervention may be limited to lifestyle changes only, but this decision should be accompanied by close follow-up.</li> <li>• In white-coat hypertensives with a higher CV risk or hypertension-mediated organ damage, drug treatment may be considered in addition to lifestyle changes.</li> <li>• In masked hypertension, both lifestyle measures and antihypertensive drug treatment should be considered, because this type of hypertension has been consistently found to have a CV risk very close to that of in- and out-of-office hypertension.</li> <li>• Antihypertensive drug up-titration should be considered in treated patients whose out-of-office BP is not controlled (i.e., masked uncontrolled hypertension), because of the high CV risk of these patients.</li> </ul> <p><u>Antihypertensive treatment strategies in the elderly</u></p> <ul style="list-style-type: none"> <li>• It is recommended that older patients (≥65 years) are treated with the same recommendations in non-older patient population. In very old patients (≥80 years), it may be appropriate to initiate treatment with monotherapy.</li> <li>• In all older patients, when combination therapy is used, it is recommended that this is initiated at the lowest available doses. In all older patients, and especially very old or frail patients, the possible occurrence of postural BP should be closely monitored and symptoms of possible hypotensive episodes checked by ambulatory blood pressure monitoring.</li> <li>• Unless required for concomitant diseases, loop diuretics and alpha-blockers should be avoided because of their association with injurious falls.</li> <li>• Renal function should be frequently assessed to detect possible increases in serum creatinine and reductions in estimated glomerular filtration rate (eGFR) as a result of BP-related reductions in renal perfusion.</li> <li>• When treated, BP should be lowered to a systolic value of 130 to 139 mmHg and a diastolic value of &lt;80 mmHg if tolerated. Treated values of &lt;130 mmHg should be avoided.</li> </ul> <p><u>Treatment strategies in hypertensive women</u></p>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• Hormone therapy and selective estrogen receptor modulators are not recommended and should not be used for primary or secondary prevention of CVD.</li> <li>• In women with gestational hypertension, pre-existing hypertension superimposed by gestational hypertension, or with hypertension and subclinical organ damage or symptoms, initiation of drug treatments is recommended when SBP is <math>\geq 140</math> mmHg or DBP <math>\geq 90</math> mmHg. In all other cases, initiation of drug treatment is recommended when SBP is <math>\geq 150</math> mmHg or DBP is <math>\geq 95</math> mmHg.</li> <li>• Methyldopa, labetalol, and CCBs are recommended as the drugs of choice for the treatment of hypertension in pregnancy.</li> <li>• ACE inhibitors, ARBs, or direct renin inhibitors are not recommended during pregnancy.</li> <li>• SBP <math>\geq 170</math> mmHg or DBP <math>\geq 110</math> mmHg in a pregnant woman is an emergency, and admission to hospital is recommended.</li> <li>• In severe hypertension, drug treatment with intravenous (IV) labetalol, oral methyldopa, or nifedipine is recommended.</li> <li>• The recommended treatment for hypertensive crisis is IV labetalol or nicardipine and magnesium.</li> <li>• In pre-eclampsia associated with pulmonary edema, nitroglycerin given as an IV infusion is recommended.</li> <li>• In women with gestational hypertension or mild-pre-eclampsia, delivery is recommended at 37 weeks.</li> <li>• It is recommended to expedite delivery in pre-eclampsia with adverse conditions, such as visual disturbances or hemostatic disorders</li> <li>• In women at high risk of pre-eclampsia, provided they are at low risk of gastrointestinal hemorrhage, treatment with low dose aspirin from 12 weeks until delivery may be considered.</li> <li>• Methyldopa, labetalol, and nifedipine should be considered preferential antihypertensive drugs in pregnancy. Intravenous labetalol or infusion of nitroprusside should be considered in case of emergency (pre-eclampsia).</li> </ul> <p><u>Treatment strategies in patients with diabetes</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive drug treatment is recommended for people with diabetes when office BP is <math>\geq 140/90</math> mmHg.</li> <li>• A SBP goal <math>&lt; 130</math> mmHg is recommended in patients with diabetes and <math>&lt; 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg.</li> <li>• In older people, the target SBP range is 130 to 139 mmHg.</li> <li>• The DBP target in patients with diabetes is recommended to be <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• It is recommended to initiate treatment with a combination of a RAS blocker with a CCB or thiazide/thiazide-like diuretic.</li> <li>• It is recommended that individual drug choice takes comorbidities into account.</li> <li>• Simultaneous administration of two blockers of the RAS is not recommended and should be avoided in patients with diabetes.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with nephropathy</u></p> <ul style="list-style-type: none"> <li>• In patients with diabetic and non-diabetic CKD, it is recommended that an office BP of <math>\geq 140/90</math> mmHg be treated with lifestyle advice and BP-lowering medication.</li> <li>• In patients with diabetic or non-diabetic CKD, it is recommended to lower SBP to a range of 130 to 139 mmHg. And individualized treatments should be considered according to its tolerability and impact on renal function and electrolytes.</li> <li>• A combination of a RAS blocker with a CCB or a diuretic is recommended as initial therapy.</li> <li>• RAS blockers are more effective in reducing albuminuria than other</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>antihypertensive agents, and are indicated in hypertensive patients in the presence of microalbuminuria or overt proteinuria.</p> <ul style="list-style-type: none"> <li>• Combination of two RAS blockers, though potentially more effective in reducing proteinuria, is not recommended.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with cerebrovascular disease</u></p> <ul style="list-style-type: none"> <li>• In patients with acute intracerebral hemorrhage, immediate BP lowering is not recommended for patients with SBP &lt;220 mmHg. In patients with SBP <math>\geq</math>220 mmHg, care acute BP lowering with IV therapy to &lt;180 mmHg should be considered.</li> <li>• In acute ischemic stroke, routine BP lowering with antihypertensive therapy is not recommended with the exceptions with the exceptions: in patients with acute ischemic stroke who are eligible for IV thrombolysis, BP should be carefully lowered and maintained at &lt;180/105 mmHg for at least the first 24 hours after thrombolysis; In patients with markedly elevated BP who do not receive fibrinolysis, drug therapy may be considered, based on clinical judgement, to reduce BP by 15% during the first 24 hours after the stroke onset.</li> <li>• In hypertensive patients with an acute cerebrovascular event, antihypertensive treatment is recommended immediately for transient ischemic attack (TIA) and after several days in ischemic stroke.</li> <li>• In all hypertensive patients with ischemic stroke or TIA, an SBP target range of 120 to 130 mmHg should be considered.</li> <li>• The recommended antihypertensive drug treatment strategy for stroke prevention is a RAS blocker plus a CCB or a thiazide-like diuretic.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with heart failure (HF) or left ventricular hypertrophy (LVH)</u></p> <ul style="list-style-type: none"> <li>• In hypertensive patients with heart failure (with reduced or preserved ejection fraction), BP-lowering treatment should be considered if <math>\geq</math>140/90 mmHg.</li> <li>• In patients with HF<sub>r</sub>EF, it is recommended that BP-lowering treatment comprises an ACE inhibitor or ARB, and a beta-blocker and a diuretic and/or mineralocorticoid receptor antagonist (MRA) if required.</li> <li>• Dihydropyridine CCBs may be added if BP control is not achieved.</li> <li>• In patients with HF<sub>p</sub>EF, BP treatment threshold and target values should be the same as for HF<sub>r</sub>EF).</li> <li>• Because no specific drug has proven its superiority, all major agents can be used.</li> <li>• In all patients with LVH, it is recommended to treat with a RAS blocker or in combination with a CCB or diuretic and SBP should be lowered to a range of 120 to 130 mmHg.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• In patients with CAD receiving BP-lowering drugs, it is recommended to target SBP to <math>\leq</math>130 mmHg if tolerated, but not &lt;120 mmHg. In older patients, the target is an SBP range of 130 to 140 mmHg. The target DBP is &lt;80 mmHg, but not &lt;70 mmHg.</li> <li>• In hypertensive patients with a history of myocardial infarction, beta-blockers and RAS blockers are recommended as part of treatment.</li> <li>• In patients with asymptomatic angina, beta-blockers and/or CCBs are recommended.</li> </ul>
<p>National Institute for Health and Clinical Excellence: <b>Hypertension in adults: diagnosis</b></p>	<p><u>Choosing antihypertensive drug treatment (for people with or without type II diabetes)</u></p> <ul style="list-style-type: none"> <li>• Where possible, recommend treatment with drugs taken only once a day.</li> <li>• Prescribe non-proprietary drugs where these are appropriate and minimize cost.</li> <li>• Offer people with isolated systolic hypertension (systolic blood pressure <math>\geq</math>160 mmHg) the same treatment as people with both raised systolic and diastolic blood</li> </ul>

Clinical Guideline	Recommendation(s)
<p><b>and management (2019)<sup>11</sup></b></p>	<p>pressure.</p> <ul style="list-style-type: none"> <li>• Offer antihypertensive drug treatment to women of child-bearing potential with diagnosed hypertension in line with recommendations in this guideline. For women considering pregnancy or who are pregnant or breastfeeding, manage hypertension in line with the recommendations on Management of pregnancy with chronic hypertension and Breastfeeding in 'Hypertension in pregnancy'.</li> <li>• When choosing antihypertensive drug treatment for adults of black African or African-Caribbean family origin, consider an angiotensin II receptor blocker, in preference to an angiotensin-converting enzyme inhibitor.</li> </ul> <p><u>Step one treatment</u></p> <ul style="list-style-type: none"> <li>• Patients &lt;55 years of age should be offered a step one antihypertensive with an angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB).</li> <li>• Offer an ACE inhibitor or an ARB to adults starting step 1 antihypertensive treatment who have type II diabetes and are of any age or family origin or those aged &lt;55 years but not of black African or African-Caribbean family origin.</li> <li>• If an ACE inhibitor is not tolerated, offer an ARB.</li> <li>• Do not combine an ACE inhibitor with an ARB for the treatment of hypertension.</li> <li>• Offer a calcium channel blocker (CCB) to adults starting step 1 antihypertensive treatment who are &gt;55 years of age and do not have diabetes and are of black African or African-Caribbean family origin and do not have type II diabetes and of any age.</li> <li>• If a CCB is not suitable, for example because of edema or intolerance, or if there is evidence of heart failure or a high risk of heart failure, offer a thiazide-like diuretic.</li> <li>• If diuretic treatment is to be initiated or changed, offer a thiazide-like diuretic, such as indapamide in preference to a conventional thiazide diuretic such as bendroflumethiazide or hydrochlorothiazide.</li> <li>• For adults with hypertension who are already receiving treatment with bendroflumethiazide or hydrochlorothiazide, who have stable, well-controlled blood pressure, continue with their treatment.</li> </ul> <p><u>Step two treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering next step treatment for hypertension discuss with the person if they are taking their medicine as prescribed and support adherence in line with NICE's guideline on "Medicines adherence: involving patients decisions about prescribed medicines and supporting adherence".</li> <li>• If hypertension is not controlled with a step one treatment of an ACE inhibitor or ARB, offer choice of one of the following drugs in addition to the step one treatment: a CCB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults taking step one treatment of a CCB, offer the choice of one of the following drugs in addition to the step one treatment: an ACE inhibitor or an ARB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults of black African or African-Caribbean family origin who do not have type 2 diabetes taking step one treatment, consider an ARB, in preference to an ACE inhibitor, in addition to step one treatment.</li> </ul> <p><u>Step three treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering step three treatment, review the person's medications to ensure they are being taken at the optimal doses and discuss adherence (see recommendation under step two).</li> <li>• If hypertension is not controlled in adults taking step two treatment, offer a combination of an ACE inhibitor or ARB and a CCB and a thiazide-like diuretic.</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><u>Step four treatment</u></p> <ul style="list-style-type: none"> <li>• If hypertension is not controlled in adults taking the optimal tolerated doses of an ACE inhibitor or an ARB plus a CCB and a thiazide-like diuretic, regard them as having resistant hypertension.</li> <li>• Before considering further treatment for a person with resistant hypertension, confirm elevated clinic blood pressure measurements using ambulatory or home blood pressure recordings, assess for postural hypotension, and discuss adherence.</li> <li>• For people with confirmed resistant hypertension, consider adding a fourth antihypertensive drug as step four treatment or seeking specialist advice.</li> <li>• Consider further diuretic therapy with low-dose spironolactone for adults with resistant hypertension starting step four treatment who have a blood potassium level of 4.5 mmol/l or less. Use particular caution in people with a reduced estimated glomerular filtration rate because they have an increased risk of hyperkalemia.</li> <li>• When using further diuretic therapy for step four treatment of resistant hypertension, monitor blood sodium and potassium and renal function within one month of starting treatment and repeat as needed thereafter.</li> <li>• Consider an alpha-blocker or beta-blocker for adults with resistant hypertension starting step four treatment who have a blood potassium level of more than 4.5 mmol/l.</li> <li>• If blood pressure remains uncontrolled in people with resistant hypertension taking the optimal tolerated doses of four drugs, seek specialist advice.</li> </ul>
<p>International Society on Hypertension in Blacks: <b>Management of High Blood Pressure in Blacks (2010)</b><sup>12</sup></p>	<ul style="list-style-type: none"> <li>• To attain and maintain blood pressure (BP) below target levels, multiple antihypertensive drugs will be required in most hypertensive blacks.</li> <li>• Use of two-drug combination therapy when SBP is &gt;15 mm Hg and/or DBP is &gt;10 mm Hg above goal levels is increasingly recommended as first-line therapy.</li> <li>• Two-drug regimens have generally contained a thiazide-type diuretic; however, the combination of a calcium channel blocker (CCB) with either an ACE inhibitor or an ARB has been shown equally efficacious in BP lowering but with demonstrated superiority (CCB+ACE) for hard clinical outcomes compared with the same ACE inhibitor plus a thiazide-type diuretic.</li> <li>• In secondary prevention patients, the combination therapy should include a drug(s) with the appropriate compelling indications.</li> <li>• Certain classes of antihypertensive medications, specifically diuretics and CCBs, lower BP on average more than <math>\beta</math>-blockers and renin-angiotensin system (RAS) blockers in black patients when used as monotherapies.</li> <li>• In the absence of compelling indications, when BP is near goal levels, monotherapy with a diuretic or a CCB is preferred.</li> <li>• Lifestyle modifications should be initiated in all patients with hypertension, whether or not pharmacotherapy is planned.</li> <li>• ACE inhibitors or ARBs are recommended as alternative monotherapy options in the treatment of hypertension in blacks. The rationale for their lower tier monotherapy recommendation is because they have consistently achieved lesser average reductions in BP relative to that observed with monotherapy using either a diuretic or CCB.</li> </ul>
<p>Kidney Disease Improving Clinical Outcomes Group; <b>KDIGO Clinical Practice Guideline for the Management of Blood Pressure in Chronic Kidney Disease</b></p>	<p><u>Blood pressure measurement</u></p> <ul style="list-style-type: none"> <li>• The Work Group recommends standardized office blood pressure (BP) measurement in preference to routine office BP measurements for the management of high BP in adults.</li> <li>• The Work Group suggests that out-of-office BP measurements with ambulatory BP monitoring (ABPM) or home BP monitoring (HBPM) be used to complement standardized office BP readings for the management of high BP.</li> </ul> <p><u>Lifestyle interventions for lowering BP in patients with chronic kidney disease (CKD)</u></p>

Clinical Guideline	Recommendation(s)
(2021) <sup>13</sup>	<p><u>not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests targeting a sodium intake &lt;2 grams of sodium per day (or &lt;90 mmol of sodium per day, or &lt;5 grams of sodium chloride per day) in patients with high BP and CKD.</li> <li>The Work Group suggests that patients with high BP and CKD be advised to undertake moderate-intensity physical activity for a cumulative duration of at least 150 minutes per week, or to a level compatible with their cardiovascular and physical tolerance.</li> </ul> <p><u>BP management in patients with CKD, with or without diabetes, not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests that adults with high BP and CKD be treated with a target systolic BP (SBP) of &lt;120 mmHg, when tolerated, using standardized office BP measurement.</li> <li>The Work Group recommends starting renin-angiotensin-system inhibitors (RASi) (angiotensin-converting enzyme inhibitor [ACEi] or angiotensin II receptor blocker [ARB]) for people with high BP, CKD, and severely increased albuminuria without diabetes.</li> <li>The Work Group suggests starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately increased albuminuria without diabetes.</li> <li>The Work Group recommends starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately-to-severely increased albuminuria with diabetes.</li> <li>The Work Group recommends avoiding any combination of ACEi, ARB, and direct renin inhibitor (DRI) therapy in patients with CKD, with or without diabetes.</li> </ul> <p><u>BP management in kidney transplant recipients</u></p> <ul style="list-style-type: none"> <li>Treat adult kidney transplant recipients with high BP to a target BP of &lt;130 mmHg systolic and &lt;80 mmHg diastolic using standardized office BP measurement.</li> <li>The Work Group recommends that a dihydropyridine calcium channel blocker (CCB) or an ARB be used as the first-line antihypertensive agent in adult kidney transplant recipients.</li> </ul> <p><u>BP management in children with CKD</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests that in children with CKD, 24-hour mean arterial pressure by ABPM should be lowered to &lt;50<sup>th</sup> percentile for age, sex, and height.</li> </ul>
<p>American College of Cardiology/ American Heart Association Task Force: <b>Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults (2017)<sup>14</sup></b></p>	<p><u>Initiation of Blood Pressure (BP) Treatment for Overall Cardiovascular Disease (CVD) Risk</u></p> <ul style="list-style-type: none"> <li>Use of BP-lowering medications is recommended for secondary prevention of recurrent CVD events in patients with clinical CVD and an average systolic blood pressure (SBP) ≥130 mmHg or an average diastolic blood pressure (DBP) of ≥80 mmHg and for primary prevention in adults with an estimated 10-year atherosclerotic cardiovascular disease (ASCVD) risk of ≥10% and an average SBP of ≥130 mmHg or an average ≥80 mmHg.</li> <li>Use of BP-lowering medication is recommended for primary prevention of CVD in adults with no history of CVD and with an estimated 10-year ASCVD risk &lt;10% and an SBP of ≥140 mmHg or a DBP of ≥90 mmHg.</li> <li>Simultaneous use of an angiotensin converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), and/or renin inhibitor is potentially harmful and is not recommended to treat adults with hypertension.</li> <li>For adults with confirmed hypertension and known CVD or 10-year ASCVD risk of ≥10%, a BP target &lt;130/80 mmHg is recommended. For adults with confirmed hypertension without additional markers of increased CVD risk, a BP target &lt;130/80 mmHg may be reasonable.</li> <li>For initiation of antihypertensive drug therapy, first-line agents include thiazide</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>diuretics, calcium channel blockers (CCBs), and ACE inhibitors or ARBs.</p> <ul style="list-style-type: none"> <li>• Initiation of antihypertensive drug therapy with two first-line agents of different classes, either as separate agents or in a fixed-dose combination, is recommended in adults with stage 2 hypertension and an average BP &gt;20/10 mmHg above their BP target.</li> <li>• Initiation of antihypertensive drug therapy with a single antihypertensive drug is reasonable in adults with stage 1 hypertension and BP goal &lt;130/80 mmHg with dosage titration and sequential addition of other agents to achieve the BP target.</li> </ul> <p><u>Stable Ischemic Heart Disease (SIHD)</u></p> <ul style="list-style-type: none"> <li>• In adults with SIHD and hypertension, a BP target &lt;130/80 is recommended.</li> <li>• Adults with SIHD and hypertension (BP ≥130/80 mmHg) should be treated with medications [e.g., guideline-directed medical therapy (GDMT) beta-blockers, ACE inhibitors, or ARBs] for compelling indications [e.g., previous myocardial infarction (MI), stable angina] as first-line therapy, with the addition of other drugs (e.g., dihydropyridine CCBs, thiazide diuretics, and/or mineralocorticoid receptor antagonists) as needed to further control hypertension.</li> <li>• In adults with SIHD with angina and persistent uncontrolled hypertension, the addition of dihydropyridine CCBs to GDMT beta-blockers is recommended.</li> <li>• In adults who have had a MI or acute coronary syndrome, it is reasonable to continue GDMT beta-blockers beyond three years as long-term therapy for hypertension.</li> <li>• Beta-blockers and/or CCBs might be considered to control hypertension in patients with coronary artery disease (CAD) had an MI more than three years ago and have angina.</li> </ul> <p><u>Heart Failure</u></p> <ul style="list-style-type: none"> <li>• In adults with increased risk of HF, the optimal BP in those with hypertension should be &lt;130 mmHg.</li> <li>• Adults with HFrEF and hypertension should be prescribed GDMT titrated to attain a BP &lt;130/80 mmHg.</li> <li>• Non-dihydropyridine CCBs are not recommended in the treatment of hypertension in adults with HFrEF.</li> <li>• In adults with HFpEF who present with symptoms of volume overload, diuretics should be prescribed to control hypertension.</li> <li>• Adults with HFpEF and persistent hypertension after management of volume overload should be prescribed ACE inhibitors or ARBs and beta-blockers titrated to attain SBP &lt;130 mmHg.</li> </ul> <p><u>CKD</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and CKD should be treated to a BP goal &lt;130/80 mmHg.</li> <li>• In adults with hypertension and CKD [stage 3 or higher or stage 1 or 2 with albuminuria (≥300 mg/d, or ≥300 mg/g albumin-to-creatinine ratio or the equivalent in the first morning void)], treatment with an ACE inhibitor is reasonable to slow kidney disease progression. Treatment with an ARB may be reasonable if an ACE inhibitor is not tolerated.</li> <li>• After kidney transplantation, it is reasonable to treat patients with hypertension to a BP goal &lt;130/80 mmHg and with a CCB on the basis of improved glomerular filtration rate (GFR) and kidney survival.</li> </ul> <p><u>Cerebrovascular Disease</u></p> <ul style="list-style-type: none"> <li>• In adults with intracerebral hemorrhage (ICH) who present with SBP &gt;220 mmHg, it is reasonable to use continuous intravenous (IV) drug infusion and close BP monitoring to lower levels. Immediate lowering of SBP to &lt;140 mmHg in adults with spontaneous ICH who present within six hours of the acute event and have an</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>SBP between 150 mmHg and 220 mmHg is not of benefit to reduce death or severe disability and can be potentially harmful.</p> <ul style="list-style-type: none"> <li>• Adults with acute ischemic stroke and elevated BP who are eligible for treatment with IV tissue plasminogen activator (tPA) should have their BP slowly lowered to &lt;185/110 mmHg before thrombolytic therapy is initiated.</li> <li>• In adults with an acute ischemic stroke, BP should be &lt;185/110 mmHg before administration of IV tPA and should be maintained below 180/105 mmHg for at least the first 24 hours after initiation drug therapy.</li> <li>• Starting or restarting antihypertensive therapy during hospitalization in patients with BP &gt;140/90 mmHg who are neurologically stable is safe and reasonable to improve long-term BP control, unless contraindicated.</li> <li>• In patient with BP <math>\geq</math>220/120 mmHg who did not receive IV alteplase or endovascular treatment and have no comorbid conditions requiring acute antihypertensive treatment, the benefit of initiating or reinitiating treatment of hypertension within the first 48 to 72 hours is uncertain. It might be reasonable to lower BP by 15% during the first 24 hours after onset of stroke. In patients with BP &lt;220/120 mmHg with the same conditions, initiating or reinitiating treatment of hypertension within the first 48 to 72 hours after an acute ischemic stroke is not effective to prevent death or dependency.</li> <li>• Adults with previously treated stroke or transient ischemic attack should be restarted on antihypertensive treatment after the first few days of the index event to reduce the risk of recurrent stroke and other vascular events. Treatment with a thiazide diuretic, ACE inhibitor, or ARB, or combination treatment consisting of a thiazide diuretic plus ACE inhibitor, is useful.</li> <li>• Adults not previously treated for hypertension who experienced a stroke or transient ischemic attack and have an established BP <math>\geq</math>140/90 mmHg should be prescribed antihypertensive treatment a few days after the index event to reduce the risk of recurrent stroke and other vascular event.</li> <li>• For adults who experience a stroke or transient ischemic attack, selection of specific drugs should be individualized on the basis of patient comorbidities and agent pharmacological class.</li> <li>• For adults who experience a stroke or transient ischemic attack, a BP goal &lt;130/80 mmHg may be reasonable.</li> <li>• For adults with a lacunar stroke, a target SBP goal &lt;130 mmHg may be reasonable.</li> <li>• In adults previously untreated for hypertension who experience an ischemic stroke or transient ischemic attack and have an SBP &lt;140 mmHg and a DBP &lt;90 mmHg, the usefulness of initiating antihypertensive treatment is not well established.</li> </ul> <p><u>Peripheral Artery Disease (PAD)</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and PAD should be treated similarly to patients with hypertension without PAD.</li> </ul> <p><u>Diabetes Mellitus (DM)</u></p> <ul style="list-style-type: none"> <li>• In adults with DM and hypertension, antihypertensive drug treatment should be initiated at a BP of <math>\geq</math>130/80 mmHg with a treatment goal &lt;130/80 mmHg.</li> <li>• In adults with DM and hypertension, all first-line classes of antihypertensive agents (i.e., diuretics, ACE inhibitors, ARBs, and CCBs) are useful and effective.</li> <li>• In adults with DM and hypertension, ACE inhibitors or ARBs may be considered in the presence of albuminuria.</li> </ul> <p><u>Atrial Fibrillation, Valvular Heart Disease, and Aortic disease</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension can be useful for prevention of recurrence of AF.</li> <li>• In adults with asymptomatic aortic stenosis, hypertension should be treated with pharmacotherapy, starting at a low dose and gradually titrating upward as needed.</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>• In patients with chronic aortic insufficiency, treatment of systolic hypertension with agents that do not slow the heart rate (i.e., avoid beta-blockers) is reasonable.</li> <li>• Beta-blockers are recommended as the preferred antihypertensive agents in patients with hypertension and thoracic aortic disease.</li> </ul> <p><u>Racial and Ethnic Differences in Treatment</u></p> <ul style="list-style-type: none"> <li>• In black adults with hypertension but without HF or CKD, including those with DM, initial antihypertensive treatment should include a thiazide-type diuretic or CCB. Two or more antihypertensive medications are recommended to achieve a BP target &lt;130/80 mmHg in most adults with hypertension, especially in black adults with hypertension.</li> </ul> <p><u>Pregnancy</u></p> <ul style="list-style-type: none"> <li>• Women with hypertension who become pregnant, or are planning to become pregnant, should be transitioned to methyldopa, nifedipine, and/or labetalol during pregnancy.</li> <li>• Women with hypertension who become pregnant should not be treated with ACE inhibitors, ARBs, or direct renin inhibitors.</li> </ul> <p><u>Older Persons</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension with an SBP treatment goal &lt;130 mmHg is recommended for noninstitutionalized ambulatory community-dwelling adults (≥65 years of age) with an average SBP of ≥130 mmHg.</li> <li>• For older adults (≥65 years of age) with hypertension and a higher burden of comorbidity and limited life expectancy, clinical judgment, patient preference, and a team-based approach to assess risk/benefit is reasonable for decisions regarding intensity of BP lowering and choice of antihypertensive drugs.</li> </ul> <p><u>Hypertensive Crises</u></p> <ul style="list-style-type: none"> <li>• In adults with a hypertensive emergency, admission to an intensive care unit is recommended for continuous monitoring of BP and target organ damage and for parenteral administration of an appropriate agent.</li> <li>• For adults with a compelling condition (i.e., aortic dissection, severe pre-eclampsia or eclampsia, or pheochromocytoma crisis), SBP should be reduced to &lt;140 mmHg during the first hour and to &lt;120 mmHg in aortic dissection.</li> <li>• For adults without a compelling condition, SBP should be reduced by no more than 25% within the first hours; then, if stable, to 160/100 mmHg within the next two to six hours; and then cautiously to normal during the following 24 to 48 hours.</li> </ul> <p><u>Cognitive Decline and Dementia</u></p> <ul style="list-style-type: none"> <li>• In adults with hypertension, BP lowering is reasonable to prevent cognitive decline and dementia.</li> </ul> <p><u>Patients Undergoing Surgical Procedures</u></p> <ul style="list-style-type: none"> <li>• In patients with hypertension undergoing major surgery who have been on beta-blockers chronically, beta-blockers should be continued.</li> <li>• In patients with hypertension undergoing planned elective major surgery, it is reasonable to continue medical therapy for hypertension until surgery.</li> <li>• In patients with hypertension undergoing major surgery, discontinuation of ACE inhibitors or ARBs perioperatively may be considered.</li> <li>• In patients with planned elective major surgery and SBP ≥180 mmHg or DBP ≥110 mmHg, deferring surgery may be considered.</li> <li>• For patients undergoing surgery, abrupt pre-operative discontinuation of beta-blockers or clonidine is potentially harmful.</li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>Beta-blockers should not be started on the day of surgery in beta-blocker-naïve patients.</li> <li>Patients with intraoperative hypertension should be managed with IV medications until such time as oral medications can be resumed.</li> </ul>
<p>American Diabetes Association: <b>Standards of Medical Care in Diabetes (2022)</b><sup>15</sup></p>	<p><b>Hypertension/blood pressure control</b></p> <ul style="list-style-type: none"> <li>Blood pressure should be measured at every routine visit. When possible, patients found to have elevated blood pressure (<math>\geq 140/90</math>) should have blood pressure confirmed using multiple readings, including measurements on a separate day, to diagnose hypertension. Patients with blood pressure <math>\geq 180/110</math> and cardiovascular disease could be diagnosed with hypertension at a single visit.</li> <li>All hypertensive patients with diabetes should monitor their blood pressure at home.</li> <li>For patients with diabetes and hypertension, with diabetes and hypertension, blood pressure targets should be individualized through a shared decision-making process that addresses cardiovascular risk, potential adverse effects of antihypertensive medications, and patient preferences.</li> <li>For individuals with diabetes and hypertension at higher cardiovascular risk (existing atherosclerotic cardiovascular disease [ASCVD] or 10-year ASCVD risk <math>\geq 15\%</math>), a blood pressure target of <math>&lt;130/80</math> mmHg may be appropriate, if it can be safely attained.</li> <li>For individuals with diabetes and hypertension at lower risk for cardiovascular disease (10-year atherosclerotic cardiovascular disease risk <math>&lt;15\%</math>), treat to blood pressure target of <math>&lt;140/90</math>.</li> <li>In pregnant patients with diabetes and preexisting hypertension, a blood pressure target of 110 to 135/85 is suggested in the interest of reducing the risk for accelerated maternal hypertension and minimizing impaired fetal growth.</li> <li>For patients with blood pressure <math>&gt;120/80</math>, lifestyle intervention consists of weight loss when indicated, a Dietary Approaches to Stop Hypertension (DASH)-style eating pattern including reducing sodium and increasing potassium intake, moderation of alcohol intake, and increased physical activity.</li> <li>Patients with confirmed office-based blood pressure <math>\geq 140/90</math> mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of pharmacologic therapy to achieve blood pressure goals.</li> <li>Patients with confirmed office-based blood pressure <math>\geq 160/100</math> mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of two drugs or a single pill combination of drugs demonstrated to reduce cardiovascular events in patients with diabetes.</li> <li>Treatment for hypertension should include drug classes demonstrated to reduce cardiovascular events in patients with diabetes (ACE inhibitors, angiotensin receptor blockers, thiazide-like diuretics, or dihydropyridine calcium channel blockers). ACE inhibitors or angiotensin receptor blockers are recommended first-line therapy for hypertension in people with diabetes and coronary artery disease.</li> <li>Multiple-drug therapy is generally required to achieve blood pressure targets (but not a combination of ACE inhibitors and angiotensin receptor blockers).</li> <li>An ACE inhibitor or angiotensin receptor blocker, at the maximum tolerated dose indicated for blood pressure treatment, is the recommended first-line treatment for hypertension in patients with diabetes and urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine or 30 to 299 mg/g creatinine. If one class is not tolerated, the other should be substituted.</li> <li>For patients treated with an ACE inhibitor, angiotensin receptor blocker, or diuretic, serum creatinine/estimated glomerular filtration rate and serum potassium levels should be monitored at least annually.</li> <li>Patients with hypertension who are not meeting blood pressure targets on three classes of antihypertensive medications (including a diuretic) should be considered for mineralocorticoid receptor antagonist therapy.</li> </ul>

Clinical Guideline	Recommendation(s)
	<p><b>Chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>• At least once a year, assess urinary albumin (e.g., spot urinary albumin-to-creatinine ratio) and estimated glomerular filtration rate in patients with type 1 diabetes with duration of five or more years and in all patients with type 2 diabetes.</li> <li>• Patients with diabetes and urinary albumin <math>\geq 300</math> mg/g creatinine and/ or an estimated glomerular filtration rate 30 to 60 mL/min/1.73 m<sup>2</sup> should be monitored twice annually to guide therapy.</li> <li>• Optimize glucose control to reduce the risk or slow the progression of chronic kidney disease (CKD).</li> <li>• For patients with type 2 diabetes and diabetic kidney disease, use of a sodium-glucose cotransporter 2 inhibitor in patients with an estimated glomerular filtration rate <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> and urinary albumin <math>\geq 300</math> mg/g creatinine is recommended to reduce CKD progression and cardiovascular events.</li> <li>• In patients with type 2 diabetes and CKD, consider use of sodium-glucose cotransporter 2 inhibitors additionally for cardiovascular risk reduction when estimated glomerular filtration rate and urinary albumin creatinine are <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> or <math>\geq 300</math> mg/g, respectively.</li> <li>• In patients with CKD who are at increased risk for cardiovascular events or CKD progression and are unable to use a sodium-glucose cotransporter 2 inhibitor, a nonsteroidal mineralocorticoid receptor antagonist (finerenone) is recommended to reduce CKD progression and cardiovascular events.</li> <li>• Optimize blood pressure control and reduce blood pressure variability to reduce the risk or slow the progression of CKD.</li> <li>• Do not discontinue renin-angiotensin system blockade for minor increases in serum creatinine (<math>\leq 30\%</math>) in the absence of volume depletion.</li> <li>• For people with nondialysis-dependent stage 3 or higher CKD, dietary protein intake should be a maximum of 0.8 g/kg body weight per day (the recommended daily allowance). For patients on dialysis, higher levels of dietary protein intake should be considered, since malnutrition is a major problem in some dialysis patients.</li> <li>• In nonpregnant patients with diabetes and hypertension, either an ACE inhibitor or an angiotensin receptor blocker is recommended for those with modestly elevated urinary albumin-to-creatinine ratio (30 to 299 mg/g creatinine) and is strongly recommended for those with urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine and/or estimated glomerular filtration rate <math>&lt; 60</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Periodically monitor serum creatinine and potassium levels for the development of increased creatinine or changes in potassium when ACE inhibitors, angiotensin receptor blockers, or diuretics are used.</li> <li>• An ACE inhibitor or an angiotensin receptor blocker is not recommended for the primary prevention of CKD in patients with diabetes who have normal blood pressure, normal urinary albumin-to-creatinine ratio (<math>&lt; 30</math> mg/g creatinine), and normal estimated glomerular filtration rate.</li> <li>• Patients should be referred for evaluation by a nephrologist if they have an estimated glomerular filtration rate <math>&lt; 30</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Promptly refer to a nephrologist for uncertainty about the etiology of kidney disease, difficult management issues, and rapidly progressing kidney disease.</li> </ul>
<p>American Association for the Study of Liver Diseases: <b>Diagnosis, Evaluation, and Management of</b></p>	<p><b>Treatment of ascites</b></p> <ul style="list-style-type: none"> <li>• Moderate sodium restriction (2 g or 90 mmol/day) and diuretics (spironolactone with or without furosemide) are the first-line treatment in patients with cirrhosis and grade 2 ascites.</li> <li>• After ascites is adequately mobilized, attempts should be made to taper the diuretics to the lowest dose necessary to maintain minimal or no ascites to prevent the development of adverse effects.</li> </ul>

Clinical Guideline	Recommendation(s)
Ascites, Spontaneous Bacterial Peritonitis and Hepatorenal Syndrome: 2021 Practice Guidance (2021) <sup>16</sup>	<ul style="list-style-type: none"> <li>Fluid restriction is not necessary unless serum sodium is &lt;125 mmol/L.</li> <li>In patients receiving diuretics, body weight and serum creatinine and sodium should be regularly monitored to assess response and to detect the development of adverse effects.</li> <li>Human albumin solution (20 to 40 g/week) or baclofen administration (10 mg/day, with a weekly increase of 10 mg/day, up to 30 mg/day) can be considered in cases of severe muscle cramps.</li> <li>Large-volume paracentesis is the first-line treatment of grade 3 ascites. After paracentesis, sodium restriction and diuretics should be started.</li> <li>Referral for liver transplant evaluation should be considered in patients with grade 2 or 3 ascites.</li> <li>Nonsteroidal anti-inflammatory drugs, angiotensin-converting enzyme inhibitors, and angiotensin receptor blockers should be avoided in patients with cirrhosis and ascites.</li> <li>Aminoglycosides should be avoided whenever possible in the treatment of bacterial infections.</li> <li>For patients with cirrhosis and diuretic-responsive ascites, controversial data suggest potential benefits of long-term infusion of human albumin solution. At present, no recommendation can be made for its use in routine clinical practice.</li> </ul>

### III. Indications

The Food and Drug Administration (FDA)-approved indications for the thiazide-like diuretics are noted in Table 3. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 3. FDA-Approved Indications for the Thiazide-Like Diuretics<sup>1-3</sup>**

Indication	Chlorthalidone*	Indapamide	Metolazone
<b>Edema</b>			
Adjunctive therapy in edema associated with congestive heart failure, hepatic cirrhosis, and corticosteroid and estrogen therapy	✓		
Treatment of salt and fluid retention associated with congestive heart failure		✓	
Treatment of salt and water retention, including edema accompanying congestive heart failure			✓
Treatment of salt and water retention, including edema accompanying renal disease, including the nephrotic syndrome and states of diminished renal function			✓
<b>Hypertension</b>			
Treatment of hypertension	✓ †	✓ †	✓ †

\*Chlorthalidone is also useful in the treatment of edema due to various forms of renal dysfunction such as nephrotic syndrome, acute glomerulonephritis, and chronic renal failure.

†Alone or in combination with other antihypertensive agents.

### IV. Pharmacokinetics

The pharmacokinetic parameters of the thiazide-like diuretics are listed in Table 4.

**Table 4. Pharmacokinetic Parameters of the Thiazide-Like Diuretics<sup>4</sup>**

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life (hours)
Chlorthalidone	65	75	Not reported	Renal (50 to 74)	40 to 60
Indapamide	100	71 to 79	Liver, extensive (% not reported)	Bile (23) Feces (16 to 20) Renal (60 to 70)	14 to 15
Metolazone	40 to 65	Not reported	Not reported	Renal (56)	8 to 14

## V. Drug Interactions

Major drug interactions with the thiazide-like diuretics are listed in Table 5.

**Table 5. Major Drug Interactions with the Thiazide-Like Diuretics<sup>4</sup>**

Generic Name(s)	Interaction	Mechanism
Thiazide-like diuretics (chlorthalidone, indapamide, metolazone)	Dofetilide	Increased potassium excretion caused by thiazide diuretic administration Hypokalemia may occur.
Thiazide-like diuretics (chlorthalidone, indapamide, metolazone)	Lithium	Thiazide-like diuretics may decrease the renal excretion of lithium and produce elevated serum lithium concentrations with toxicity.
Thiazide-like diuretics (chlorthalidone, indapamide, metolazone)	Digitalis glycosides	Excretion of potassium and magnesium is increased by thiazide-like diuretics. Potassium and magnesium depletion can sensitize the myocardium to the toxic effects of digitalis glycosides.
Thiazide-like diuretics (chlorthalidone, indapamide, metolazone)	Loop diuretics (Bumetanide, ethacrynic acid, furosemide, torsemide)	Both groups have synergistic effects that may result in profound diuresis and serious electrolyte abnormalities
Thiazide-like diuretics (chlorthalidone, indapamide, metolazone)	NSAIDs	Concurrent use of NSAIDs and thiazide-like diuretics may result in reduced diuretic effectiveness and possible nephrotoxicity.
Thiazide-like diuretics (chlorthalidone, metolazone)	Bepridil	Concurrent use of thiazide-like diuretics and bepridil may result in hypokalemia and subsequent cardiotoxicity (torsades de pointes).
Thiazide-like diuretics (chlorthalidone, metolazone)	Flecainide	Concurrent use of thiazide-like diuretics and flecainide may result in increased risk of electrolyte imbalance and subsequent cardiotoxicity.

NSAIDs=nonsteroidal anti-inflammatory drugs

## VI. Adverse Drug Events

The most common adverse drug events reported with the thiazide-like diuretics are listed in Table 6. The boxed warning for metolazone is listed in Table 7.

**Table 7. Boxed Warning for Metolazone<sup>1</sup>**

<b>WARNING</b>
Do not interchange Zaroxolyn <sup>®</sup> tablets and other formulations of metolazone that share its slow and incomplete bioavailability and are not therapeutically equivalent at the same doses to Mykrox <sup>®*</sup> tablets, a more rapidly available and completely bioavailable metolazone product. Formulations bioequivalent to Zaroxolyn <sup>®</sup> and formulations bioequivalent to Mykrox <sup>®*</sup> should not be interchanged for one another.

\* Mykrox<sup>®</sup> is no longer available in the United States.

## VII. Dosing and Administration

The usual dosing regimens for the thiazide-like diuretics are listed in Table 8.

**Table 8. Usual Dosing Regimens for the Thiazide-Like Diuretics<sup>1-4</sup>**

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
Chlorthalidone	<u>Edema:</u> Tablet: initial, 50 to 100 mg/day or 100 mg on alternate days; maintenance, 90 to 120 mg on alternate days or 120 mg/day  <u>Hypertension:</u> Tablet: initial, 12.5 to 25 mg/day; maintenance, 25 to 100 mg/day	Safety and efficacy in children have not been established.	Tablet: 15 mg 25 mg 50 mg
Indapamide	<u>Edema:</u> Tablet: initial, 2.5 mg/day; maintenance, 2.5 to 5 mg/day  <u>Hypertension:</u> Tablet: initial, 1.25 mg/day; maintenance, 2.5 to 5 mg/day	Safety and efficacy in children have not been established.	Tablet: 1.25 mg 2.5 mg
Metolazone	<u>Edema:</u> Tablet: 5 to 20 mg/day  <u>Hypertension:</u> Tablet: initial, 2.5 to 5 mg/day, maintenance, 5 to 20 mg/day	Safety and efficacy in children have not been established.	Tablet: 2.5 mg 5 mg 10 mg

## VIII. Effectiveness

Clinical studies evaluating the safety and efficacy of the thiazide-like diuretics are summarized in Table 9.

**Table 9. Comparative Clinical Trials with the Thiazide-Like Diuretics**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>SHEP Cooperative Research Group<sup>17</sup> and Kostis et al.<sup>18</sup> (1991 and 1995) SHEP</p> <p>Chlorthalidone 12.5 mg QD</p> <p>vs</p> <p>placebo</p> <p>Dosage was doubled for patients failing to achieve SBP goals. If SBP goal was not reached with chlorthalidone 25 mg QD, atenolol 25 mg QD or matching placebo was added to the drug regimen. Reserpine 0.05 mg QD or matching placebo was substituted in patients with contraindications</p>	<p>DB, MC, PC, RCT</p> <p>Patients aged ≥60 years with SBP between 160 and 219 mm Hg and DBP &lt;90 mm Hg</p>	<p>N=4,736</p> <p>Mean 4.5 years</p>	<p>Primary: Total stroke</p> <p>Secondary: Sudden or rapid cardiac death (defined as death within 1 hour or within 1 to 24 hours of the onset of severe cardiac symptoms), nonfatal or fatal MI, other cardiovascular death, TIA</p>	<p>Primary: With a mean follow-up of 4.5 years, the stroke occurred in 103 patients in the active treatment group compared to 159 patients in the placebo group (RR, 0.64; 95% CI, 0.5 to 0.82; P=0.0003).</p> <p>Stroke incidence was lower in patients taking active treatment compared to placebo in all baseline age groups: 60 to 69 years (34 vs 47 events, respectively), 70 to 79 years (48 vs 74 events, respectively), 80+ years (21 vs 38 events, respectively).</p> <p>The results were stratified according to whether patients had had previous antihypertensive therapy or not. In both stratified groups, there was a decrease in the risk of stroke with active treatment compared to placebo. For patients who were not receiving antihypertensive medication at initial contact, the RR, of stroke was 0.69 (95% CI, 0.51 to 0.95; P=0.02).</p> <p>For patients who had been receiving antihypertensive medication at initial contact, the RR, of stroke was 0.57 (95% CI, 0.38 to 0.85; P=0.01).</p> <p>Secondary: There were 23 sudden and 21 rapid deaths in the active treatment group compared to 23 sudden and 24 rapid deaths in the placebo group (RR, 1.0; 95% CI, 0.56 to 1.78 vs RR, 0.87; 95% CI, 0.48 to 1.56, respectively).</p> <p>There were 50 nonfatal and 15 fatal MIs in the active treatment group compared to 74 nonfatal and 26 fatal MIs in the placebo group (RR, 0.67; 95% CI, 0.47 to 0.96 vs RR, 0.57; 95% CI, 0.30 to 1.18, respectively).</p> <p>There were 21 other cardiovascular deaths in the active treatment group compared to 25 in the placebo group (RR, 0.87; 95% CI, 0.49 to 1.55).</p> <p>There were 62 TIAs in the active treatment group compared to 82 in the</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
to atenolol.				<p>placebo group (RR, 0.75; 95% CI, 0.54 to 1.4).</p> <p>In the combined endpoints, the RR, of nonfatal MI or coronary heart disease death was 0.73 (95% CI, 0.57 to 0.94), CHD was 0.75 (95% CI, 0.60 to 0.94), cardiovascular disease was 0.68 (95% CI, 0.58 to 0.79).</p> <p>The RR, for atenolol were 0.84 (95% CI, 0.54 to 1.30) for death, 1.34 (95% CI, 0.80 to 2.28) for stroke, and 1.17 (95% CI, 0.71 to 1.61) for cardiovascular disease.</p> <p>The RR, for reserpine were 0.65 (95% CI, 0.26 to 1.59) for death, 0.27 (95% CI, 0.04 to 2.26) for stroke, and 0.55 (95% CI, 0.20 to 1.49) for cardiovascular disease.</p>
<p>ALLHAT Collaborative Research Group<sup>19</sup> (2000) ALLHAT</p> <p>Chlorthalidone 12.5 to 25 mg QD</p> <p>vs</p> <p>doxazosin 2 to 8 mg QD</p>	<p>AC, DB, MC, RCT</p> <p>Patients aged 55 years or older who had stage 1 or stage 2 HTN with ≥1 additional risk factor for CHD events (including previous MI or stroke &gt;6 months ago, left ventricular hypertrophy or echocardiography, history of type 2 diabetes, current cigarette smoking, high density lipoprotein cholesterol &lt;35 mg/dL, or documentation of other atherosclerotic cardiovascular</p>	<p>N=24,335</p> <p>Median 3.3 years</p>	<p>Primary: Fatal CHD or nonfatal MI combined</p> <p>Secondary: All cause mortality, fatal and nonfatal stroke, combined CHD, combined cardiovascular disease, cancer, end-stage renal disease</p>	<p>Primary: There was no significant difference in the primary outcome between doxazosin and chlorthalidone treatments (risk ratio, 1.13; 95% CI, 0.90 to 1.17; P=0.71).</p> <p>Secondary: Total mortality did not differ between the doxazosin and chlorthalidone treatments (four year rates, 9.62 and 9.08%, respectively; RR, 1.13; 95% CI, 0.90 to 1.15; P=0.56).</p> <p>The doxazosin group, compared with the chlorthalidone group, had a higher risk of stroke (RR 1.19; 95% CI, 1.01 to 1.40; P=0.04) and combined cardiovascular disease (four year rates 25.45 vs 21.76%; RR, 1.25; 95% CI, 1.17 to 1.33; P&lt;0.001).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
	disease)			
Black et al. <sup>20</sup> (2008) ALLHAT  Chlorthalidone 12.5 to 25 mg QD  vs  amlodipine 2.5 to 10 mg QD  vs  lisinopril 10 to 40 mg QD	MC, RCT  Men and women, age 55 years old and older, with HTN and metabolic syndrome	N=17,515  4.9 years (mean)	Primary: Fatal coronary heart disease and nonfatal MI  Secondary: All cause mortality, fatal and nonfatal stroke, combined coronary heart disease, combined cardiovascular disease	Primary: For patients with metabolic syndrome, there was no significant difference in rates of coronary heart disease and nonfatal MI with amlodipine vs chlorthalidone (RR, 0.96; 95% CI, 0.79 to 1.16), or lisinopril vs chlorthalidone (RR, 1.15; 95% CI, 0.88 to 1.27).  Secondary: For patients with metabolic syndrome, there were no significant differences found between amlodipine vs chlorthalidone in all secondary endpoints (P value not significant).  For patients without metabolic syndrome, amlodipine treatment was associated with significantly more heart failure, but in patients with metabolic syndrome, there was no difference (P=0.03).  Patients with metabolic syndrome who received lisinopril experienced more heart failure and cardiovascular disease than those who received chlorthalidone (RR, 1.31; 95% CI, 1.04 to 1.64 and RR, 1.19; 95% CI, 0.97 to 1.32).
ALLHAT Collaborative Research Group <sup>21</sup> (2002) ALLHAT  Chlorthalidone 12.5 to 25 mg/day  vs  amlodipine 2.5 to 10 mg/day  vs  lisinopril 10 to 40	DB, MC, RCT  Patients ≥55 years with HTN and ≥1 additional CHD risk factor	N=33,357  4.9 years (mean)	Primary: Combined fatal CHD or nonfatal MI  Secondary: All-cause mortality, fatal and nonfatal stroke, combined CHD, combined cardiovascular disease (combined CHD, stroke, treated angina without hospitalization,	Primary: There were no significant differences in the primary outcome between lisinopril (11.4%), amlodipine (11.3%), and chlorthalidone (11.5%).  Secondary: All-cause mortality did not differ between groups.  Five year SBPs were significantly higher in the lisinopril (2 mm Hg; P<0.001) and amlodipine groups (0.8 mm Hg; P=0.03) compared to chlorthalidone, and five year DBPs were significantly lower with amlodipine (0.8 mm Hg; P<0.001).  Amlodipine had a higher six year rate of heart failure compared to chlorthalidone (10.2 vs 7.7%; RR, 1.38; 95% CI, 1.25 to 1.52).  Lisinopril had a higher six year rate of combined cardiovascular disease (33.3 vs 30.9%; RR, 1.10; 95% CI, 1.05 to 1.16); stroke (6.3 vs 5.6%; RR,

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
mg/day			heart failure, and PAD)	1.15; 95% CI, 1.02 to 1.30) and heart failure (8.7 vs 7.7%; RR, 1.19; 95% CI, 1.07 to 1.31).
Rahman et al. <sup>22</sup> (2012) ALLHAT  Chlorthalidone 12.5 to 25 mg/day  vs  amlodipine 2.5 to 10 mg/day  vs  lisinopril 10 to 40 mg/day	Long-term, post-trial, follow-up  Patients in ALLHAT stratified based on eGFR	N=31,350  4 to 8 years	Primary: Cardiovascular mortality  Secondary: Total mortality, CHD, cardiovascular disease, stroke, heart failure, ESRD	Primary: After an average of 8.8 years of follow-up, total mortality was significantly higher in patients with moderate/severe eGFR reduction (eGFR <60 mL/min/1.73 m <sup>2</sup> ) compared to patients with normal/increased (eGFR ≥90 mL/min/1.73 m <sup>2</sup> ) and mildly reduced eGFR (eGFR 60 to 89 mL/min/1.73 m <sup>2</sup> ) (P<0.001).  In patients with moderate/severe eGFR reduction, there was no significant difference in cardiovascular mortality between chlorthalidone and amlodipine (P=0.64), or chlorthalidone and lisinopril (P=0.56).  Secondary: No significant differences were observed for any of the secondary endpoints among eGFR reduction groups.
Muntner et al. <sup>23</sup> (2014) ALLHAT  Chlorthalidone 12.5 to 25 mg/day  vs  amlodipine 2.5 to 10 mg/day  vs  lisinopril 10 to 40 mg/day	Post-hoc analysis of ALLHAT  Patients in ALLHAT with 5, 6, or 7 visits in 6 to 28 months of follow-up	N=24,004  6 to 28 months	Primary: Visit-to-visit variability (VVV) of blood pressure  Secondary: Not reported	Primary: Each measure of VVV of SBP was lower among participants randomized to chlorthalidone and amlodipine compared with those randomized to lisinopril. All four VVV of SBP metrics were lower among participants randomized to amlodipine vs chlorthalidone after full multivariable adjustment.  After multivariable adjustment including mean SBP across visits and compared with participants randomized to chlorthalidone, participants randomized to amlodipine had a 0.36 (standard error [SE]: 0.07) lower standard deviation (SD) of SBP and participants randomized to lisinopril had a 0.77 (SE=0.08) higher SD of SBP. Results were consistent using other VVV of SBP metrics. These data suggest chlorthalidone and amlodipine are associated with lower VVV of SBP than lisinopril.  Secondary: Not reported

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>Bangalore et al.<sup>24</sup> (2017) ALLHAT</p> <p>Chlorthalidone 12.5 to 25 mg/day</p> <p>vs</p> <p>amlodipine 2.5 to 10 mg/day</p> <p>vs</p> <p>lisinopril 10 to 40 mg/day</p>	<p>Post-hoc analysis of ALLHAT</p> <p>Patients in ALLHAT with average blood pressure <math>\geq 140</math> mmHg systolic or <math>\geq 90</math> mm Hg diastolic on <math>\geq 3</math> antihypertensive medications, or blood pressure <math>&lt; 140/90</math> mmHg on <math>\geq 4</math> antihypertensive medications (i.e., identified as having apparent treatment-resistant hypertension) at 2-year follow up</p>	<p>N=14,684</p> <p>4.9 years (mean)</p>	<p>Primary: Combined fatal CHD or nonfatal MI</p> <p>Secondary: All-cause mortality, fatal and nonfatal stroke, combined CHD, combined cardiovascular disease (combined CHD, stroke, treated angina without hospitalization, heart failure, and PAD)</p>	<p>Primary: Of participants assigned to chlorthalidone, amlodipine, or lisinopril, 9.6%, 11.4%, and 19.7%, respectively, had treatment-resistant hypertension. During mean follow-up of 2.9 years, primary outcome incidence was similar for those assigned to chlorthalidone compared with amlodipine or lisinopril (amlodipine- vs chlorthalidone-adjusted HR, 0.86; 95% CI, 0.53 to 1.39; P=0.53; lisinopril- vs chlorthalidone-adjusted HR, 1.06; 95% CI, 0.70 to 1.60; P=0.78).</p> <p>Secondary: Secondary outcome risks were similar for most comparisons except coronary revascularization, which was higher with amlodipine than with chlorthalidone (HR, 1.86; 95% CI, 1.11 to 3.11; P=0.02). An as-treated analysis based on diuretic use produced similar results.</p>
<p>Pupita et al.<sup>25</sup> (1983)</p> <p>Chlorthalidone 50 mg QD</p> <p>vs</p> <p>furosemide 25 mg QD</p>	<p>RCT, XO</p> <p>Men and women with a mean age of <math>53.9 \pm 9.2</math> years with mild to moderate HTN</p>	<p>N=36</p> <p>12 months</p>	<p>Primary: Blood pressure</p> <p>Secondary: Plasma electrolytes, adverse events</p>	<p>Primary: Patients taking chlorthalidone had significantly lower SBP at each monthly measurement compared to baseline (P&lt;0.01). However, only DBP values at month five were significant compared to baseline (P&lt;0.05).</p> <p>Patients taking furosemide had significantly lower SBP at months three, four, and five compared to baseline (P&lt;0.05 for month three, and P&lt;0.01 for months four and five). DBP values were significantly lower at all monthly measurements compared to baseline in patients taking furosemide (P&lt;0.01).</p> <p>At month one, SBP decreased by 19.4 mm Hg with chlorthalidone and by 21.2 mm Hg with furosemide (P&lt;0.001). DBP decreased by 11 mm Hg with chlorthalidone and by 12.6 mm Hg with furosemide at month one (P&lt;0.001).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>Secondary: There were no significant changes in serum sodium levels with either chlorthalidone or furosemide. Patients taking chlorthalidone had significantly lower serum chloride levels compared to baseline at all points (P&lt;0.01), whereas patients taking furosemide had significantly lower levels only at month six (P&lt;0.05). Both chlorthalidone and furosemide significantly reduced serum potassium levels at all points compared to baseline (P&lt;0.01).</p> <p>Patient taking chlorthalidone reported adverse effects including dizziness, transient abdominal disorder, and slight weakness. Patients taking furosemide reported transient early weakness and irritability. The rate of adverse events was not statistically significant in either treatment group.</p>
<p>Bakris et al.<sup>26</sup> (2012)</p> <p>Azilsartan medoxomil and chlorthalidone (single pill)</p> <p>vs</p> <p>azilsartan medoxomil and HCTZ (co-administered)</p> <p>Treatments were titrated to a target of &lt;140/90 mm Hg (or &lt;130/80 mm Hg if diabetes of chronic kidney disease)</p>	<p>DB, RCT</p> <p>Patients aged ≥18 years with stage 2 primary HTN</p>	<p>N=609</p> <p>10 weeks (after 2 week placebo run-in)</p>	<p>Primary: Change in trough, seated clinic systolic blood pressure at weeks 6 and 10</p> <p>Secondary: Change from baseline in clinic DBP and 24-hour mean systolic and diastolic blood pressures by ambulatory blood pressure monitoring</p>	<p>Primary: Change in SBP at week six demonstrated a mean difference of -5.6 mm Hg (95% CI, -8.3 to -2.9; P&lt;0.001) in favor of the chlorthalidone group. Fewer patients in the chlorthalidone group required titration to a higher dose of diuretic (P&lt;0.001). At the end of week 10, a greater mean SBP reduction was maintained in the chlorthalidone group compared to the HCTZ group (-5.0 mm Hg; 95% CI, -7.5 to -2.5; P&lt;0.001).</p> <p>Secondary: The chlorthalidone group demonstrated a significantly greater reduction in 24-hour mean SBP at weeks six and 10. For both clinica and 24-hour mean DBP, greater blood pressure reduction was observed in the chlorthalidone group compared to the HCTZ group at both study points.</p>
<p>Ernst et al.<sup>27</sup> (2006)</p>	<p>RCT, SB, XO</p>	<p>N=30</p>	<p>Primary: Comparison of the</p>	<p>Primary: At week eight, there was a greater reduction in 24-hour mean SBP with</p>

Finnerty et al. <sup>33</sup> (1980)  Chlorthalidone 50 mg plus reserpine 0.25 mg  vs  HCTZ 50 mg plus reserpine 0.125 mg	DB  Patients with essential HTN unresponsive to diet control and diuretic therapy	N=57  6 weeks	Primary: The change in mean DBP from baseline  Secondary: Incidence of frequent or severe side effects	Primary: The chlorthalidone plus reserpine group had a mean decrease in DBP of 17.0 mm Hg at study endpoint compared with a mean decrease of 18.6 mm Hg in the HCTZ plus reserpine group.  At study completion both treatment groups achieved diastolic control of at least 5 mm Hg below the targeted diastolic goal of 90 mm Hg.  Secondary: There were no reports of frequent or severe side effects in either treatment group.
Akram et al. <sup>34</sup> (2007) NATIVE  Indapamide SR 1.5 mg QD added to background antihypertensive therapy	OL  Patients remaining hypertensive (145 to 180/95 to 105 mm Hg) while receiving an ACE inhibitor, $\beta$ -blocker, calcium-channel blocker, ARBs, $\alpha$ -blocker, or other therapy	N=1,941  3 months	Primary: Blood pressure  Secondary: Glucose and cholesterol levels	Primary: At three months, SBP and DBP both decreased significantly compared to baseline. SBP had a change from 166 $\pm$ 16 mm Hg at baseline to 132 $\pm$ 12 mm Hg at three months. DBP had a change from 102 $\pm$ 8 mm Hg at baseline to 83 $\pm$ 6 mm Hg at three months (P<0.0001 for both).  At study end, 84% of patients achieved target SBP of $\leq$ 140 mm Hg and 61% achieved blood pressure normalization (SBP/DBP <140/90 mm Hg).  Secondary: Glucose and cholesterol levels were unaffected by indapamide SR.
Beckett et al. <sup>35</sup> (2008) HYVET  Indapamide 1.5 mg/day  vs  placebo  Perindopril 2 to 4 mg/day or matching placebo	DB, MC, PC, RCT  Patients $\geq$ 80 years (mean age 84 years) with sustained SBP $\geq$ 160 mm Hg	N=3,845  1.8 years (mean)	Primary: Fatal or nonfatal stroke  Secondary: Death from any cause, death from cardiovascular causes, death from stroke	Primary: At two years, 73.4% of patients in the active-treatment groups were receiving indapamide plus perindopril. Mean blood pressure while sitting was 15.0/6.1 mm Hg lower with active-treatment than placebo.  Active treatment was associated with a 30% reduction in the rate of fatal or nonfatal stroke (95% CI, -1 to 51; P=0.06).  Secondary: Active treatment was associated with a 21% reduction in the rate of death from any cause (95% CI, 4 to 35; P=0.02), a 23% reduction in the rate of death from cardiovascular causes (95% CI, -1 to 40; P=0.06) and a 39% reduction in the rate of death from stroke (95% CI, 1 to 62; P=0.05).

**IX. Cost**

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of '\$' signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 10. Relative Cost of the Thiazide-Like Diuretics**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost
Chlorthalidone	tablet*	Thalitone®	\$\$\$\$	\$
Indapamide	tablet*	N/A	N/A	\$
Metolazone	tablet*	N/A	N/A	\$\$

\*Generic is available in at least one dosage form or strength.  
N/A=Not available

**X. Conclusions**

The thiazide-like diuretics are approved for the treatment of hypertension and edema associated with congestive heart failure. Chlorthalidone and metolazone are also indicated for the treatment of edema due to renal dysfunction. Additionally, chlorthalidone is approved for the adjunctive treatment of edema associated with hepatic cirrhosis, as well as corticosteroid and estrogen therapy.<sup>1-4</sup> All of the agents are available in a generic formulation.

Guidelines recommend the use of diuretics and sodium restriction for the management of ascites due to cirrhosis. Spironolactone is recommended as first-line therapy, either as monotherapy or in combination with furosemide. Amiloride or eplerenone are alternative treatment options in patients experiencing gynecomastia with spironolactone.<sup>16</sup>

For the treatment of chronic heart failure, guidelines recommend the use of diuretics in all patients who have evidence of volume overload. Loop diuretics are generally recommended as initial therapy in patients with left ventricular dysfunction. For those with persistent fluid retention despite treatment with a loop diuretic, a thiazide diuretic or metolazone may be added to the regimen. In patients with normal left ventricular function, either a thiazide diuretic or loop diuretic may be used as initial therapy to manage fluid overload.<sup>7-9</sup>

There are several national and international organizations that have published guidelines on the treatment of hypertension. Thiazide-type diuretics are frequently recommended as initial therapy in patients with uncomplicated hypertension.<sup>7-13</sup> According to the National Heart, Lung, and Blood Institute's Eighth Report of The Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 8), thiazide-type diuretics should be utilized first-line for most patients with hypertension, either alone or in combination with another hypertensive from a different medication class (e.g., ACE inhibitors, ARBs,  $\beta$ -blockers, calcium channel blockers).<sup>7</sup> Several guidelines consistently recommend that the selection of an antihypertensive agent be based on compelling indications for use.<sup>7-15</sup> Most patients will require more than one antihypertensive medication to achieve blood pressure goals.<sup>7-13</sup>

In clinical trials, the thiazide-like diuretics have been shown to effectively lower blood pressure.<sup>17-44</sup> There were no studies found in the medical literature that directly compared the efficacy and safety of the thiazide-like diuretics for the treatment of hypertension.

There is insufficient evidence to support that one brand thiazide-like diuretic is safer or more efficacious than another. Formulations without a generic alternative should be managed through the medical justification portion of the prior authorization process.

Therefore, all brand thiazide-like diuretics within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

## **XI. Recommendations**

No brand thiazide-like diuretic is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

**Alabama Medicaid Agency  
Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Vasopressin Antagonists  
AHFS Class 402828  
May 4, 2022**

**I. Overview**

Conivaptan is an injectable product that is Food and Drug Administration (FDA)-approved for the treatment of euvolemic and hypervolemic hyponatremia in hospitalized patients. Conivaptan is not indicated for the treatment of congestive heart failure as the effectiveness of this agent has not been established in such patients.<sup>1</sup> Tolvaptan is an oral vasopressin antagonist that is FDA-approved for the treatment of clinically significant euvolemic and hypervolemic hyponatremia (serum sodium <125 mEq/L or less marked hyponatremia that is symptomatic and has resisted correction with fluid restriction), including patients with heart failure and Syndrome of Inappropriate Antidiuretic Hormone (SIADH).<sup>2</sup> The major disorders associated with euvolemic hyponatremia include SIADH, nephrogenic syndrome of inappropriate antidiuresis (NSIAD), glucocorticoid deficiency, hypothyroidism, exercise-associated hyponatremia (EAH), low solute intake, and primary polydipsia. Hypervolemic hyponatremia is most often caused by heart failure, cirrhosis, nephrotic syndrome, as well as acute and chronic renal failure.<sup>3</sup> Tolvaptan is now also available under the brand name Jynarque®, which is indicated to slow kidney function decline in adults at risk of rapidly progressing autosomal dominant polycystic kidney disease (ADPKD).<sup>4</sup> ADPKD is a hereditary disease characterized by renal cysts that are visible by ultrasonographic imaging studies. Patients with ADPKD can present with hypertension, hematuria, proteinuria, or kidney function impairment, detected by routine laboratory examinations. Flank pain is the most common symptom reported by patients.<sup>5</sup> ADPKD slowly progresses to chronic kidney disease and ultimately end-stage renal disease.<sup>5</sup>

Hyponatremia is frequently associated with elevated plasma levels of arginine vasopressin (AVP). AVP is normally secreted in response to increased plasma osmolality, decreased blood volume, or decreased blood pressure. Suppression of AVP secretion occurs when osmolality falls below a certain threshold, which results in renal excretion of free water. Failure to suppress AVP secretion may result in water retention and hyponatremia.<sup>3</sup> The use of traditional diuretics leads to both water and electrolyte excretion (diuresis); whereas, the use of tolvaptan leads to an increase in water excretion only (aquaresis), a decrease in urine osmolality, and an increase in serum sodium concentration. Urinary excretion of sodium and potassium, as well as plasma potassium concentrations, are not significantly affected by tolvaptan.<sup>2</sup>

The management of hyponatremia depends on the clinical presentation and duration of the disease (acute versus chronic hyponatremia). Therapeutic options include treating the underlying disease (if possible), fluid restriction, sodium chloride administration, and diuresis. Patients with chronic mild hyponatremia are often asymptomatic and treatment consists of fluid restriction or isotonic saline administration.<sup>6</sup> Acute severe hyponatremia requires more aggressive initial therapy as it may increase morbidity and mortality. Treatment of hyponatremia must be approached carefully as overly rapid correction may cause osmotic demyelination. Symptoms of osmotic demyelination are often irreversible and include quadriparesis, paraparesis, dysphagia, dysarthria, diplopia, seizures, coma, and death.<sup>3,6</sup>

The vasopressin antagonists that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. **Tolvaptan is available in a generic formulation.** This class was last reviewed in February 2020.

**Table 1. Vasopressin Antagonists Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
Conivaptan	injection <sup>^</sup>	Vaprisol®	none
Tolvaptan	tablet	Jynarque®, Samsca®*	<b>tolvaptan</b>

\*Generic is available in at least one dosage form or strength.

<sup>^</sup>Product is primarily administered in an institution.

PDL=Preferred Drug List

## II. Evidence-Based Medicine and Current Treatment Guidelines

Current treatment guidelines that incorporate the use of the vasopressin antagonists are summarized in Table 2.

**Table 2. Treatment Guidelines Using the Vasopressin Antagonists**

Clinical Guideline	Recommendation(s)
<p>American Journal of Medicine: <b>Diagnosis, Evaluation, and Treatment of Hyponatremia: Expert Panel Recommendations (2013)</b><sup>3</sup></p>	<p><u>General information</u></p> <ul style="list-style-type: none"> <li>• There are no data to suggest that the etiology of the hyponatremia, nor the methodology used to correct hyponatremia, alters the susceptibility for producing osmotic demyelination with overly rapid correction.</li> <li>• The rate of correction of hyponatremia must be taken into account before deciding on the most appropriate therapy for any patient with hyponatremia.</li> <li>• Patients with acute (&lt;48 hours) hyponatremia may present with alarming neurologic findings, and they sometimes die of brain herniation. When hyponatremia develops over several days, brain swelling is minimized so that patients with chronic (&lt;48 hours) hyponatremia have more modest symptoms and almost never die of brain herniation.</li> </ul> <p><u>Rate of correction of hyponatremia</u></p> <ul style="list-style-type: none"> <li>• To reverse serious manifestations of acute hyponatremia, increasing serum sodium by 4 to 6 mmol/L is sufficient to prevent brain herniation and neurological damage from cerebral ischemia.</li> <li>• The rate of correction does not need to be restricted in patients with true acute hyponatremia, nor is re-lowering of excessive corrections indicated; however, if there is any uncertainty as to whether the hyponatremia is chronic versus acute, then the limits for correction of chronic hyponatremia should be followed.</li> <li>• In patients with chronic hyponatremia, neurologic sequelae are associated with more rapid rates of correction. The osmotic demyelination syndrome (ODS) can usually be avoided by limiting correction of chronic hyponatremia to 4 to 8 mmol/L in 24 hours for those at low-risk of ODS and to 4 to 6 mmol/L/day for those at high-risk.</li> <li>• Limits not to exceed: 8 mmol/L in any 24-hour period for high-risk patients and 10 to 12 mmol/L in any 24-hour period or 18 mmol/L in any 48-hour period in patients at normal risk.</li> <li>• Factors that place patients at high risk of developing ODS include serum sodium concentration <math>\leq 105</math> mmol/L, hypokalemia, alcoholism, malnutrition, and advanced liver disease.</li> </ul> <p><u>Conventional therapy of euvolemic hyponatremia</u></p> <ul style="list-style-type: none"> <li>• Treatment of patients with euvolemic hyponatremia will vary greatly depending on their presentation. The single most important factor guiding initial therapy is the presence of neurologic symptoms.</li> <li>• Cases of acute hyponatremia (<math>\leq 48</math> hours in duration) are usually symptomatic if the hyponatremia is severe (<math>\leq 120</math> mmol/L). These patients are at greatest risk from neurologic complications from the hyponatremia itself and should be corrected to higher serum sodium levels promptly.</li> <li>• Patients with more chronic hyponatremia (<math>&gt;48</math> hours in duration) who have minimal neurologic symptomatology are at little risk from complications of hyponatremia itself, but can develop osmotic demyelination following rapid correction. There is no indication to correct these patients rapidly, and they should be treated using slower-acting therapies.</li> <li>• Syndrome of inappropriate antidiuretic hormone secretion:             <ul style="list-style-type: none"> <li>○ Correction of acute symptomatic hyponatremia is best accomplished with hypertonic (3%) saline given via bolus or continuous infusion. Intravenous furosemide 20 to 40 mg should be used to treat volume overload. Acute treatment should be discontinued when the patient's symptoms are abolished, a safe serum sodium level (<math>\geq 120</math> mmol/L) is achieved, or a total</li> </ul> </li> </ul>

Clinical Guideline	Recommendation(s)
	<p>correction of 18 mmol/L is achieved.</p> <ul style="list-style-type: none"> <li>○ For the treatment of mild-to-moderate chronic hyponatremia, fluid restriction represents the least toxic therapy, and has generally been the treatment of choice. Several days of restriction are usually necessary before a significant increase in plasma osmolality occurs.</li> <li>○ Pharmacologic interventions are reserved for refractory cases where the degree of fluid restriction required to avoid hypo-osmolality is so severe that the patient is unable, or unwilling, to maintain it. The preferred drug is demeclocycline, which causes a nephrogenic form of diabetes insipidus. Treatment must be continued for several days to achieve maximal diuretic effects. Other agents, such as lithium, have similar renal effects but are less desirable because of inconsistent results and significant side effects and toxicities. Urea is as an alternative treatment for syndrome of inappropriate antidiuretic hormone secretion.</li> </ul> <ul style="list-style-type: none"> <li>● Glucocorticoid deficiency: <ul style="list-style-type: none"> <li>○ Glucocorticoid replacement should be started immediately after completion of a rapid adrenocorticotropic hormone stimulation test. Several days of glucocorticoids are sometimes required for normalization of the plasma osmolality. Primary treatment of hyponatremia may be indicated if significant neurologic symptoms are present.</li> </ul> </li> <li>● Hypothyroidism: <ul style="list-style-type: none"> <li>○ The primary therapy of hypothyroidism is thyroid hormone replacement.</li> <li>○ Hyponatremia with hypothyroidism is infrequent and generally of mild severity; therefore, modest fluid restriction is generally the only treatment necessary.</li> <li>○ Symptomatic hyponatremia may be seen in patients with more severe hypothyroidism and altered mental status, primary treatment of hyponatremia may be indicated to ascertain whether the hyponatremia is contributing to the patient's neurologic symptoms.</li> </ul> </li> <li>● Exercise-associated hyponatremia (EAH): <ul style="list-style-type: none"> <li>○ EAH can be severe and life threatening as a result of cerebral edema and noncardiogenic pulmonary edema.</li> <li>○ Hyponatremia occurring in the setting of endurance exercise is acute, and treatment of symptomatic hyponatremia should be rapid.</li> <li>○ With significant central nervous system impairment, hypertonic saline should begin immediately and continued until the serum sodium reaches 125 mmol/L or symptoms resolve.</li> </ul> </li> <li>● Low solute intake: <ul style="list-style-type: none"> <li>○ Hyponatremia from low solute intake is corrected by instituting proper nutrition, with increased content of solute both as electrolytes and protein.</li> </ul> </li> <li>● Primary polydipsia: <ul style="list-style-type: none"> <li>○ Therapy should be directed at reducing fluid intake into the normal range.</li> <li>○ Fluid ingestion in patients with psychogenic causes of polydipsia responds variably to behavior modification and pharmacologic therapy (e.g., clozapine).</li> </ul> </li> </ul> <p><u>Conventional therapy of hypervolemic hyponatremia</u></p> <ul style="list-style-type: none"> <li>● For all diseases associated with edema formation, dietary sodium restriction and diuretic therapy are the mainstays of therapy.</li> <li>● Congestive heart failure (CHF): <ul style="list-style-type: none"> <li>○ For severely symptomatic patients with very low or rapidly falling serum sodium, treatment should consist of hypertonic (3%) NaCl combined with loop diuretics to prevent fluid overload; for patients with mild to moderate symptoms, begin with fluid restriction (1 L/d total) and, if signs of volume overload are present, administer loop diuretics.</li> <li>○ If the serum sodium does not correct to the desired level, lift the fluid</li> </ul> </li> </ul>

Clinical Guideline	Recommendation(s)
	<p>restriction and start either conivaptan (if intravenous route is preferred or required) or tolvaptan (if oral therapy is preferred).</p> <ul style="list-style-type: none"> <li>○ Hyponatremia in HF is almost always chronic, so current limits for rate of correction of chronic hyponatremias should be observed.</li> <li>○ If tolvaptan is used, it may be up-titrated from 15 to 30 to 60 mg/d as necessary to achieve the desired level of correction of serum sodium.</li> <li>○ Continue treatment until the serum sodium has either normalized, symptoms have improved, or the level of serum sodium is no longer compromising administration of needed diuretic therapy.</li> </ul> <ul style="list-style-type: none"> <li>● The stimuli for AVP secretion may be more dynamic than in other disease states; if prescribed after discharge, assessing the need for chronic therapy of hyponatremia by providing a window of observation off therapy two to four weeks after treatment initiation is a reasonable approach.</li> <li>● Cirrhosis: <ul style="list-style-type: none"> <li>○ There are no guidelines specifically regarding treatment of hyponatremia in cirrhosis.</li> <li>○ Demeclocycline is relatively contraindicated because of a high incidence of nephrotoxicity, and urea has not been used often. Fluid restriction is the usual approach, but without outcome studies to assess its effectiveness.</li> </ul> </li> <li>● Nephrotic syndrome, acute and chronic renal failure: <ul style="list-style-type: none"> <li>○ In patients with hyponatremia with advanced acute and chronic renal failure and glomerular filtration rate &lt;20 mL/min, fluid restriction to amounts less than insensible losses plus urine output is generally necessary to cause a negative solute-free water balance and correction of hyponatremia.</li> <li>○ Vaptans can be employed in selected cases where fluid restriction is not successful or not well tolerated.</li> </ul> </li> </ul> <p><u>Use of vasopressin receptor antagonists in hyponatremia</u></p> <ul style="list-style-type: none"> <li>● Exclude hypovolemic hyponatremia.</li> <li>● Do not use in conjunction with other treatments for hyponatremia.</li> <li>● Do not use immediately after cessation of other treatments for hyponatremia, particularly 3% NaCl.</li> <li>● Monitor serum sodium closely (every 6 to 8 hours) for the first 24 to 48 hours after initiating treatment.</li> <li>● Maintain ad libitum fluid intake during the first 24 to 48 hours of treatment; hyponatremia can correct too quickly with coincidental fluid restriction; in patients with a defective or impaired thirst mechanism (e.g., intubated or unconscious patients), provide sufficient fluid to prevent overly rapid correction due to unopposed aquaresis.</li> <li>● Increase the frequency of serum sodium monitoring and consider stopping the vaptan if there is a change or deterioration in the patient's condition (e.g., nothing-by-mouth status, intubation) that limits the ability to request, access, or ingest fluid.</li> <li>● Severe, symptomatic hyponatremia should be treated with 3% NaCl, as this provides a quicker and more certain correction of serum sodium than vaptans.</li> <li>● Currently, there are insufficient data for use of vaptans in severe asymptomatic hyponatremia (serum sodium &lt;120 mmol/L)—use vaptans with caution and with more frequent monitoring in these patients.</li> <li>● If overcorrection occurs, consider re-lowering the serum sodium to safe limits.</li> <li>● For the treatment of acute severe hyponatremia, there is insufficient data from clinical trials to know if sufficiently rapid correction can be achieved with vasopressin receptor antagonists without the use of hypertonic saline.</li> <li>● Most studies to date in patients with hyponatremia have only been of relatively short duration. The most appropriate way to use these agents, their long-term response rates, how important the role of water restriction will remain during chronic use, and whether correction of chronic hyponatremia will result in improved cognitive</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>function as suggested by 30-day studies of tolvaptan, and quality of life, or functional status, as suggested by initial studies of gait stability and falls, are unknown at the present time and will require additional study.</p> <ul style="list-style-type: none"> <li>• Safety issues must be considered carefully with any new class of drugs. The possibility of overcorrection has been of significant concern in all of the vasopressin receptor antagonist clinical trials, but to date osmotic demyelination has not been reported with any agent. The potential for serious drug interactions via interference with cytochrome P450 3A4-mediated metabolism of other drugs must also be recognized. Whether there will be any adverse effect of V<sub>2</sub> receptor inhibition in vascular endothelium is unknown.</li> <li>• Further studies will be needed to assess the appropriate use of vasopressin receptor antagonists, such as for correction of symptomatic hyponatremia either alone or in conjunction with hypertonic saline infusions; to assess the benefits of correction of hyponatremia in hospitalized patients in terms of disease outcomes and decreased lengths of intensive care unit and hospital stay; and for long-term treatment of minimally symptomatic hyponatremia in order to decrease the risks of neurocognitive dysfunction and gait instability.</li> </ul>
<p>Canadian Expert Consensus: <b>Updated Canadian Expert Consensus on Assessing Risk of Disease Progression and Pharmacological Management of Autosomal Dominant Polycystic Kidney Disease (2018)<sup>9</sup></b></p>	<ul style="list-style-type: none"> <li>• All patients with a diagnosis of Autosomal Dominant Polycystic Kidney Disease (ADPKD) or suspected ADPKD should be referred to a nephrologist for initial assessment. Initial assessment should include kidney imaging and, in some cases, genetic testing to determine the patient's risk of rapid progression and to determine what treatment should be initiated.</li> <li>• Patients with ADPKD who are &lt;50 years old with eGFR &gt;60 mL/min/1.73 m<sup>2</sup> and without significant cardiovascular comorbidities should have a target blood pressure of ≤110/75 mm Hg, realizing that in some patients an individual target may be needed.</li> <li>• Consider treatment with tolvaptan for patients who fulfill the enrollment criteria of the TEMPO 3:4 study: 18 to 50 years of age with total kidney volume (TKV) &gt;750 mL and eGFR &gt;45 mL/min/1.73 m<sup>2</sup>.</li> <li>• Treatment with tolvaptan is recommended for patients who fulfill the enrollment criteria of the REPRISE study: <ul style="list-style-type: none"> <li>○ 18 to 55 years of age with eGFR of 25 to 65 mL/min/1.73 m<sup>2</sup> OR</li> <li>○ 56 to 65 years of age with eGFR of 25 to 44 mL/min/1.73 m<sup>2</sup> with historical evidence of a decline in eGFR &gt;2.0 mL/min/1.73 m<sup>2</sup>/year.</li> <li>○ Although there were no inclusion criteria for kidney size, based on the abundance of evidence that increased size of kidneys is relevant, these REPRISE criteria relate to those patients with ADPKD who have enlarged kidneys. In those patients with advanced or rapidly progressive chronic kidney disease (CKD) without enlarged kidneys, an alternate diagnosis for CKD should be investigated.</li> </ul> </li> <li>• Treatment with tolvaptan is suggested for patients who, according to the Mayo Clinic Classification, are classified as 1D or 1E with eGFR in CKD stages 1 to 4 (eGFR &gt;25 mL/min). Treatment with tolvaptan may be considered for patients who are classified as 1C and are &lt;50 years old or have other risk factors for rapid progression, such as an annual decrease in eGFR of &gt;2.5 mL/min/1.73 m<sup>2</sup> and/or increase in TKV of &gt;5% per year.</li> <li>• Treatment with tolvaptan should be stopped when the patient develops ESRD. In the predialysis setting with eGFR &lt;25 mL/min/1.73 m<sup>2</sup>, there are no data to guide when treatment with tolvaptan should be stopped.</li> <li>• Additional considerations when giving tolvaptan: <ul style="list-style-type: none"> <li>○ Patients with ADPKD on treatment with tolvaptan should follow a sodium-restricted diet of ≤2.4 g/day (≤100 mmol/day).</li> <li>○ Titrating tolvaptan to the maximal tolerated dose or to achieve a uOSM &lt;250 mOsm/kg water is suggested. Consideration should be given to consultation with a dietician to minimize sodium and osmolal intake to help manage severe aquaretic adverse events.</li> </ul> </li> </ul>

### III. Indications

The Food and Drug Administration (FDA)-approved indications for the vasopressin antagonists are noted in Table 3. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 3. FDA-Approved Indications for the Vasopressin Antagonists<sup>2</sup>**

Indication	Tolvaptan* <sup>†</sup>
To slow kidney function decline in adults at risk of rapidly progressing autosomal dominant polycystic kidney disease	✓ (Jynarque <sup>®</sup> )
Treatment of clinically significant hypervolemic and euvolemic hyponatremia (serum sodium <125 mEq/L or less marked hyponatremia that is symptomatic and has resisted correction with fluid restriction), including patients with heart failure and Syndrome of Inappropriate Antidiuretic Hormone	✓

\*Patients requiring intervention to raise serum sodium urgently to prevent or to treat serious neurological symptoms should not be treated with tolvaptan.

<sup>†</sup>It has not been established that tolvaptan provides a symptomatic benefit to patients.

### IV. Pharmacokinetics

The pharmacokinetic parameters of the vasopressin antagonists are listed in Table 4.

**Table 4. Pharmacokinetic Parameters of the Vasopressin Antagonists<sup>7</sup>**

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life (hours)
Tolvaptan	≥40	99	Liver, extensive (% not reported)	Non-renal routes	12

### V. Drug Interactions

Major drug interactions with the vasopressin antagonists are listed in Table 5. Tolvaptan is metabolized by cytochrome P450 (CYP) 3A, and use with strong CYP3A inhibitors causes a marked (5-fold) increase in exposure.<sup>1</sup> Tolvaptan is contraindicated in combination with strong cytochrome CYP3A inhibitors, such as clarithromycin, ketoconazole, itraconazole, ritonavir, indinavir, nelfinavir, saquinavir, nefazodone, and telithromycin.<sup>1</sup> The use of tolvaptan in combination with CYP3A inducers and moderate CYP3A inhibitors should also be avoided.<sup>1</sup>

**Table 5. Major Drug Interactions with the Vasopressin Antagonists<sup>7</sup>**

Generic Name	Interaction	Mechanism
Vasopressin antagonists (tolvaptan)	HIV protease inhibitors	Inhibition of CYP3A4 by HIV protease inhibitors may decrease the metabolic elimination of tolvaptan. Plasma concentrations and pharmacologic effects of tolvaptan may be increased by HIV protease inhibitors.
Vasopressin antagonists (tolvaptan)	Imidazoles	Inhibition of CYP3A4 by imidazoles may decrease the metabolic elimination of tolvaptan. Plasma concentrations and pharmacologic effects of tolvaptan may be increased by imidazoles.
Vasopressin antagonists (tolvaptan)	Macrolides and ketolides	Inhibition of CYP3A4 and P-glycoprotein by macrolides and ketolides may decrease the metabolic elimination of tolvaptan. Plasma concentrations and pharmacologic effects of tolvaptan may be increased by macrolides and ketolides.
Vasopressin antagonists (tolvaptan)	Nefazodone	Inhibition of CYP3A4 by nefazodone may decrease the metabolic elimination of tolvaptan. Plasma concentrations and pharmacologic effects of tolvaptan may be increased by nefazodone.

Generic Name	Interaction	Mechanism
Vasopressin antagonists (tolvaptan)	Moderate CYP3A4 Inhibitors	Inhibition of CYP3A isoenzymes by moderate CYP3A4 inhibitors may decrease the metabolic elimination of tolvaptan. Plasma concentrations and pharmacologic effects of tolvaptan may be increased by moderate CYP3A4 inhibitors.
Vasopressin antagonists (tolvaptan)	Rifamycins	Induction of CYP3A isoenzymes by rifamycins may increase the metabolic elimination of tolvaptan. Plasma concentrations and pharmacologic effects of tolvaptan may be decreased by rifamycins compromising therapeutic effectiveness.
Vasopressin antagonists (tolvaptan)	St. John's wort	Induction of CYP3A isoenzymes by St. John's wort may increase the metabolic elimination of tolvaptan. Plasma concentrations and pharmacologic effects of tolvaptan may be decreased by St. John's wort compromising therapeutic effectiveness.

CYP=cytochrome P450 isoenzymes, HIV=human immunodeficiency virus

## VI. Adverse Drug Events

The most common adverse drug events reported with the vasopressin antagonists are listed in Table 6. The boxed warning for tolvaptan is listed in Table 7.

**Table 6. Adverse Drug Events (%) Reported with the Vasopressin Antagonists<sup>8</sup>**

Adverse Events	Tolvaptan
<b>Cardiovascular</b>	
Palpitations	4
Ventricular fibrillation	<2
<b>Central Nervous System</b>	
Cerebrovascular accident	<2
Dizziness	11
Fatigue	14
Pyrexia	4
<b>Endocrine and Metabolic</b>	
Diabetic ketoacidosis	<2
Hyperglycemia	6
Hypernatremia	<4
Hyperuricemia	4
<b>Gastrointestinal</b>	
Abdominal distention	5
Anorexia	4
Constipation	7
Diarrhea	13
Dyspepsia	8
Ischemic colitis	<2
Nausea	21
Xerostomia	7 to 16
<b>Genitourinary</b>	
Pollakiuria	4 to 11
Polyuria	4 to 70
Urethral bleeding	<2
Vaginal hemorrhage	<2
<b>Laboratory Abnormalities</b>	
Bilirubin increased	<1
Increased serum alanine aminotransferase	5
Prothrombin time prolonged	<2
<b>Musculoskeletal</b>	
Rhabdomyolysis	<2

Adverse Events	Tolvaptan
Weakness	9
<b>Respiratory</b>	
Pulmonary embolism	<2
Respiratory failure	<2
<b>Other</b>	
Deep vein thrombosis	<2
Dehydration	2 to 3
Disseminated intravascular coagulation	<2
Hepatotoxicity	≤4
Hypersensitivity reaction	<1
Skin rash	4
Thirst	12 to 64
Xeroderma	5

- Event not reported

**Table 7. Boxed Warning for Tolvaptan<sup>2,4</sup>**

<b>WARNING</b>	
<b>Samsca®</b>	
Initiate and re-initiate in a hospital and monitor serum sodium Samsca® should be initiated and re-initiated in patients only in a hospital where serum sodium can be monitored closely.	
<ul style="list-style-type: none"> <li>• Too rapid correction of hyponatremia (e.g., &gt;12 mEq/L/24 hours) can cause osmotic demyelination resulting in dysarthria, mutism, dysphagia, lethargy, affective changes, spastic quadriparesis, seizures, coma and death. In susceptible patients, including those with severe malnutrition, alcoholism or advanced liver disease, slower rates of correction may be advisable.</li> </ul>	
Not for use for autosomal dominant polycystic kidney disease (ADPKD)	
<ul style="list-style-type: none"> <li>• Because of the risk of hepatotoxicity, tolvaptan should not be used for ADPKD outside of the FDA-approved REMS.</li> </ul>	
<b>Jynarque®</b>	
<ul style="list-style-type: none"> <li>• Jynarque® can cause serious and potentially fatal liver injury. Acute liver failure requiring liver transplantation has been reported.</li> <li>• Measure ALT, AST and bilirubin before initiating treatment, at two weeks and four weeks after initiation, then monthly for the first 18 months and every three months thereafter. Prompt action in response to laboratory abnormalities, signs, or symptoms indicative of hepatic injury can mitigate, but not eliminate, the risk of serious hepatotoxicity.</li> <li>• Because of the risks of serious liver injury, Jynarque® is available only through a restricted distribution program under a Risk Evaluation and Mitigation Strategy (REMS) called the Jynarque REMS Program.</li> </ul>	

## VII. Dosing and Administration

The usual dosing regimens for the vasopressin antagonists are listed in Table 8.

**Table 8. Usual Dosing Regimens for the Vasopressin Antagonists<sup>2,4</sup>**

Generic Name	Usual Adult Dose	Usual Pediatric Dose	Availability
Tolvaptan	<p><u>Hypervolemic and euvoletic hyponatremia:</u> Tablet: initial, 15 mg once daily; maintenance, increase to 30 mg once daily after ≥24 hours as needed to achieve the desired level of serum sodium; maximum, 60 mg once daily</p> <p><u>Rapidly Progressing Autosomal Dominant Polycystic Kidney Disease</u></p>	Safety and effectiveness have not been established in pediatric patients.	Tablet: 15 mg 30 mg 45 mg 60 mg 90 mg

Generic Name	Usual Adult Dose	Usual Pediatric Dose	Availability
	Tablet: initial, 60 mg orally per day as 45 mg taken on waking and 15 mg taken 8 hours later; Titrate to 60 mg plus 30 mg then to 90 mg plus 30 mg per day if tolerated with at least weekly intervals between titrations		

## VIII. Effectiveness

Clinical studies evaluating the safety and efficacy of the vasopressin antagonists are summarized in Table 9.

**Table 9. Comparative Clinical Trials with the Vasopressin Antagonists**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>Gheorghide et al.<sup>10</sup> (2006)</p> <p>Tolvaptan 10 mg/day, with titration to larger doses (15, 30, 45, and 60 mg/day) as needed to achieve serum sodium concentrations within normal limits</p> <p>vs</p> <p>fluid restriction (initially 1,200 mL/24 hrs) plus placebo</p>	<p>AC, MC, OL, RCT</p> <p>Patients ≥18 years, serum sodium &lt;135 mmol/L for ≥2 consecutive days, and normovolemia or signs of fluid overload</p>	<p>N=28</p> <p>Inpatient treatment: 14 days</p> <p>Outpatient treatment: 14 days</p> <p>Follow-up: 65 days</p>	<p>Primary: Normalization of serum sodium concentration (defined as ≥135 mmol/L or an increase of &gt;10% from baseline to the last inpatient assessment)</p> <p>Secondary: Changes in serum sodium from baseline to the last outpatient visit (day 65), urine osmolality, urine volume, urine sodium concentration, body weight, total fluid intake, thirst score from baseline to the last inpatient assessment</p>	<p>Primary: A higher proportion of subjects in the tolvaptan group had achieved the normalization of serum sodium compared to those in the fluid restriction group by the last inpatient visit (P=0.049). The normalization of serum sodium was achieved more rapidly in the tolvaptan group than in the fluid restriction group, occurring in 50% of tolvaptan-treated subjects by day four, compared to day eight in the fluid restriction group (P&lt;0.03).</p> <p>Patients in the tolvaptan group had a significantly greater increase in serum sodium concentration 4 hours after the first dose (1.6 mmol/L; P=0.016), at day 5 (5.2 mmol/L; P=0.019) and at the last inpatient visit (5.7 mmol/L; P=0.0065) compared to patients receiving fluid restriction (-0.8, 0.7, and 1.0, respectively).</p> <p>Secondary: At day 65, the mean change in serum sodium was 4.7 mmol/L in the tolvaptan group compared to -0.3 mmol/L in the placebo group (P=0.039).</p> <p>Urine sodium was significantly lower (P=0.021) and urine output was significantly greater (P=0.014) in the tolvaptan group compared to the placebo group.</p> <p>No significant differences in urine osmolality (P=0.058), serum potassium (P=0.45), blood pressure, heart rate, body weight (P value not significant), thirst score (P=0.8) or adverse events requiring drug discontinuation were observed between the treatment groups.</p>
<p>Schrier et al.<sup>11</sup> (2006)</p> <p>SALT-1 and SALT-2</p> <p>Tolvaptan 15</p>	<p>DB, MC, PC, RCT</p> <p>Patients ≥18 years of age with euvolemic or hypervolemic</p>	<p>N=102 (SALT-1)</p> <p>N=123 (SALT-2)</p>	<p>Primary: Change in the average daily AUC for the serum sodium from baseline to day 4</p>	<p>Primary: By day four, the increase in the average daily AUC for the serum sodium concentration was 3.62 and 4.33 for tolvaptan (SALT-1 and SALT-2, respectively) compared to 0.25 and 0.42 for placebo (P&lt;0.001 for all comparisons).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>mg/day for 30 days (dose could be titrated to 60 mg/day)</p> <p>vs</p> <p>placebo</p>	<p>hyponatremia (serum sodium &lt;135 mmol/L). Patients also had chronic heart failure, cirrhosis, or the syndrome of inappropriate antidiuretic hormone secretion (SIADH) in association with the hyponatremia.</p>	<p>37 days</p>	<p>and from baseline to day 30</p> <p>Secondary: Change in the AUC for the serum sodium in patients with marked hyponatremia, serum sodium concentration at each visit, time to normalization of the serum sodium, percent of patients with serum sodium concentrations that normalized at day 4 and day 30, serum sodium concentration on day 4 and day 30 for patients with mild or marked hyponatremia at baseline, change from baseline in scores on the Physical Component Summary and Mental component summary of the medical outcomes Study 12-item Short-Form General Health</p>	<p>By day 30, the increase in the average daily AUC for the serum sodium concentration was 6.22 and 6.20 for tolvaptan (SALT-1 and SALT-2, respectively) compared to 1.66 and 1.84 for placebo (P&lt;0.001 for all comparisons).</p> <p>Secondary: By day 30, the increase in the average daily AUC for the serum sodium concentration in patients with marked hyponatremia was 8.24 and 7.60 for tolvaptan (SALT-1 and SALT-2, respectively) compared to 2.54 and 2.72 for placebo (P&lt;0.001 for all comparisons).</p> <p>By day four, serum sodium concentrations were 133.9 and 135.3 mmol/L for tolvaptan (SALT-1 and SALT-2, respectively) compared to 129.7 and 129.6 mmol/L for placebo (P&lt;0.001 for all comparisons). By day 30, serum sodium concentrations were 135.7 and 135.9 mmol/L for tolvaptan (SALT-1 and SALT-2, respectively) compared to 131 and 131.5 mmol/L for placebo (P&lt;0.001 for all comparisons).</p> <p>By day four, 40 and 55% of patients receiving tolvaptan (SALT-1 and SALT-2, respectively) had normal serum sodium concentrations compared to 13 and 11% for placebo (P&lt;0.001 for all comparisons). By day 30, 53 and 58% of patients receiving tolvaptan (SALT-1 and SALT-2, respectively) had normal serum sodium concentrations compared to 25 and 25% for placebo (P&lt;0.001 for all comparisons).</p> <p>Scores on the Physical Component Summary did not differ significantly between groups. Scores for the Mental Component Summary improved in the tolvaptan group when the data from SALT-1 and SALT-2 were combined (P=0.02), as well as in SALT-1 (P=0.04). Scores improved significantly in the combined subgroup of patients with marked hyponatremia (P=0.04). There was no significant difference between the groups found in SALT-2 (P=0.14).</p> <p>Adverse event profiles in the two study groups were similar for all comparisons. The most common adverse events occurring during the study in the tolvaptan groups were thirst and dry mouth. Overall, there were 26 serious adverse events potentially related to the study treatment in SALT-1</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
			Survey	<p>and SALT-2. The number of deaths in the two study groups was similar (14 deaths among 223 patients in the tolvaptan groups and 13 deaths among 220 patients in the placebo groups), and they occurred within the defined observation period.</p> <p>In four of the patients in the tolvaptan group, the desirable rates of sodium correction were exceeded during the first 24 hours of the study (&gt;0.5 mmol/L per hour). In four patients (1.8%), the predefined serum sodium concentration (&gt;146 mmol per liter) was exceeded.</p>
<p>Berl et al.<sup>12</sup> (2010) SALTWATER</p> <p>Tolvaptan QD (dose varied based on response)</p>	<p>OL, ES (Extension of SALT-1 and SALT-2)</p> <p>Patients ≥18 years of age with euvolemic or hypervolemic hyponatremia (serum sodium &lt;135 mmol/L). Patients also had chronic heart failure, cirrhosis, or the SIADH in association with the hyponatremia</p>	<p>N=111</p> <p>4 years (mean 1.9 years)</p>	<p>Primary: Safety, efficacy</p> <p>Secondary: Not reported</p>	<p>Primary:</p> <p>During the follow-up period, 105 of 111 patients experienced an adverse event. The most common adverse events that were potentially related to tolvaptan use were pollakiuria, thirst, fatigue, dry mouth, polydipsia, polyuria, hypotension, hypernatremia, dizziness, headache, peripheral edema, and acute renal failure.</p> <p>A total of 19 patients died during the follow-up period (9 deaths per 100 patient-years of exposure). The death rate during SALTWATER was lower than that observed for SALT (86.9 deaths per 100 patient-years of exposure).</p> <p>In five patients, serum sodium correction exceeded the rate of 1 mmol/L per h at the eight hour time point. There were 18 patients who had serum sodium levels &gt;145 mmol/L at individual time points.</p> <p>Correction of serum sodium levels during the first eight hours of therapy occurred at similar rates in SALTWATER compared to SALT-1 and SALT-2. After the initial titration period, mean serum sodium levels remained within the normal range throughout the four year treatment period.</p> <p>In all patient subgroups, serum sodium levels declined by seven days of withholding tolvaptan. On drug discontinuation, the proportion of patients who declined by ≥3 mEq/L was 68%, and an equal proportion fell from ≥135mEq/L to below this threshold of normal.</p> <p>The mean time to first fluid restriction was 122.3 and 162.5 days in the</p>

				mild and marked hyponatremia subgroups, respectively; 13.2% of patients in the mild hyponatremia group and 5.4% in the marked hyponatremia group required fluid restriction.  Secondary: Not reported
Cardenas et al. (abstract) <sup>13</sup> (2012) SALT-1 and SALT-2  Tolvaptan 15 mg/day for 30 days (dose could be titrated to 60 mg/day)  vs  placebo	Subgroup analysis  Patients with cirrhosis and hyponatremia	N=120  30 days	Primary: Change in the average daily AUC for the serum sodium from baseline to day 4 and from baseline to day 30  Secondary: Mental component summary of the medical outcomes Study 12-item Short-Form General Health Survey, safety	Primary: Treatment with tolvaptan effectively raised serum sodium. Average daily AUC for serum sodium was significantly greater with tolvaptan from baseline to day 4 (P<0.0001) and day 30 (P<0.0001) compared to placebo. Superiority of tolvaptan was maintained after stratification by baseline hyponatremia (mild and marked), eGFR ( $\leq 60$ and $>60$ mL/min), or serum creatinine levels ( $<1.5$ and $\geq 1.5$ mg/dL).  Hyponatremia recurred seven days after discontinuation of tolvaptan.  Secondary: Mean mental component summary scores of the Short-Form General Health Survey improved from baseline to day 30 with tolvaptan but not with placebo (4.68 vs 0.08; P=0.02).  Major adverse events with tolvaptan were dry mouth and thirst. Gastrointestinal bleeding occurred in 10 and 2% of patients receiving tolvaptan and placebo, respectively (P=0.11). Rates of adverse events, withdrawals, and deaths were similar with both treatments.
Udelson et al. <sup>14</sup> (2008)  Tolvaptan 15, 30, or 60 mg administered as a single dose  vs  placebo	DB, MC, PC, RCT  Patients $\geq 18$ years of age with symptomatic heart failure (NYHA class III or IV) of $\geq 3$ months' duration caused by LVEF $<40\%$ . Patients were also required to be on standard	N=181  12 hours	Primary: PCWP peak change from baseline within 3 to 8 h after treatment administration  Secondary: AUC for the change from baseline PCWP	Primary: The pairwise comparisons of 15, 30, and 60 mg tolvaptan versus placebo each showed a statistically significant decrease in peak change in PCWP from three to eight hours post-dose (P=0.003, P=0.044, and P=0.033, respectively).  Secondary: For the AUC <sub>0-8h</sub> , the 15 mg tolvaptan group was the only tolvaptan dose group that was statistically significantly different from placebo.  All tolvaptan doses produced statistically significantly greater changes than placebo in peak change in pulmonary artery pressure (P<0.01 for 15

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
	background therapy for heart failure for $\geq 1$ month.		and other hemodynamic parameters over an 8 hour evaluation period and renal and electrolyte parameters	<p>mg; <math>P &lt; 0.05</math> for 30 and 60 mg).</p> <p>Tolvaptan 15 and 30 mg doses resulted in statistically significant reductions in peak change in right atrial pressure as compared to placebo (<math>P &lt; 0.01</math> and <math>P &lt; 0.05</math>, respectively).</p> <p>No significant changes in cardiac index, pulmonary vascular resistance, and systemic vascular resistance were observed after tolvaptan administration compared to placebo.</p> <p>The single dose of tolvaptan produced a dose-dependent increase in urine output (<math>P &lt; 0.0001</math> for all tolvaptan groups vs placebo). Urine osmolality was significantly reduced by all doses of tolvaptan relative to placebo (<math>P &lt; 0.0001</math> for all tolvaptan groups vs placebo). Free water clearance was significantly greater for all tolvaptan doses relative to placebo at all time points. Plasma osmolality increased in all of the tolvaptan-treated groups compared to placebo. Serum sodium levels showed a dose-related increase compared to placebo (1.2, 3.3, 4.6, and -0.7 mEq/L for the tolvaptan 15, 30, 60 mg, and placebo groups, respectively). Potassium levels were not different from placebo in any of the tolvaptan dosing groups. No significant changes in serum creatinine, blood urea nitrogen, serum potassium, and vital signs were observed after study drug administration.</p> <p>Tolvaptan was well tolerated relative to placebo. Patient-reported adverse events in this short-term study occurred in 45.5, 44.2, 54.3, and 33.3% of the 15, 30, and 60 mg tolvaptan and placebo groups, respectively.</p>
<p>Udelson et al.<sup>15</sup> (2007)</p> <p>Tolvaptan 30 mg/day</p> <p>vs</p> <p>placebo</p>	<p>DB, MC, PC, RCT</p> <p>Patients <math>\geq 18</math> years of age with CHF (NYHA class II to III) with a LVEF <math>&lt; 30\%</math>. Patients were also required to be on standard background therapy for heart failure for</p>	<p>N=240</p> <p>55 weeks</p>	<p>Primary: Change from baseline in LVEDV index</p> <p>Secondary: Change from baseline in LVESV index, comparison of the change from baseline in</p>	<p>Primary: In the placebo group, there was no change in LVEDV index over the year of follow-up. After one year of tolvaptan therapy, there was a small reduction in LVEDV index; however, this was not significantly different from placebo (-1.8 mL/m<sup>2</sup>; <math>P = 0.21</math> vs placebo). There was also no difference in the change of volumes from baseline at the week 55 study.</p> <p>Secondary: In the placebo group, LVEDV index decreased 0.4 mL/m<sup>2</sup> compared to a decrease of 3.3 mL/m<sup>2</sup> in the tolvaptan group (<math>P = 0.09</math>). There was no difference in the change of LVESV index from baseline at week 55.</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
	<p>≥3 months before enrollment.</p>		<p>LVEDV index after drug withdrawal (week 55), assessment of symptoms (using subject-assessed symptom scales and the Minnesota Living With Heart Failure Questionnaire)</p>	<p>Ejection fraction changes were small and similar in both treatment groups.</p> <p>Only minor changes in blood pressure and heart rate were observed over the course of the trial; there were no significant differences in the tolvaptan versus placebo groups. There were no significant between-group differences in serum sodium or potassium across the course of the trial. There were also no differences in renal function parameters (BUN and serum creatinine) across the year of therapy.</p> <p>No statistically significant differences were observed between the tolvaptan group and the placebo group for the change from baseline in Minnesota Living With Heart Failure Questionnaire score or for the Visual Analog Scale assessment of global status or respiratory status. More subjects in the tolvaptan group reported a score of “better” in the subject-assessed overall treatment effect at each visit than did subjects in the placebo group; however, no statistically significant differences were observed between treatment groups.</p> <p>There were six deaths (5%) and 21 hospitalizations of patients with heart failure (18%) in the tolvaptan-treated group, compared to 11 deaths (9%) and 34 heart failure hospitalizations (28%) in the placebo-treated group (P&lt;0.03 for the composite of death and heart failure hospitalizations).</p> <p>Adverse events including urinary frequency, thirst, and dry mouth occurred more frequently with tolvaptan than with placebo therapy. There was no difference in the number of patients withdrawn from the trial as the result of bothersome side effects between the two randomization groups.</p>
<p>Gheorghide et al.<sup>16</sup> (2007) EVEREST  Tolvaptan 30 mg/day within 48 hours of admission  vs</p>	<p>DB, MC, PC, RCT  Patients ≥18 years of age with a history of chronic heart failure who had been hospitalized for worsening CHF and who had a LVEF ≤40%.</p>	<p>N=2,048 (Trial A)  N=2,085 (Trial B)  7 days</p>	<p>Primary: Composite score of changes from baseline in patient-assessed global clinical status and body weight at day 7 or discharge</p>	<p>Primary: The composite score of changes from baseline in patient-assessed global clinical status and body weight at day seven or discharge was greater with tolvaptan compared to placebo (Trial A, mean 16 vs 0.99; P&lt;0.001; Trial B, mean 17 vs 0.97; P&lt;0.001).</p> <p>Improvement in patient-assessed global clinical status (assessed alone), measured by a 100-point visual analog scale at day seven or discharge, was similar between the tolvaptan and placebo groups (Trial A, mean 18.25 vs 17.73; P=0.51; Trial B, mean 18.72 vs 18.28; P=0.52).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
satavaptan*, lixivaptan*)  vs  control (no intervention, placebo, other diuretics)	ascites		cirrhosis (variceal bleeding, hepatic encephalopathy, spontaneous bacterial peritonitis, and hepatorenal syndrome), renal failure, serum sodium levels, mobilization of ascites, safety	No clear differences between vaptans and control were found regarding complications to cirrhosis and renal failure.  Treatment with vaptans increased serum sodium levels (WMD, 1.8 mmol/L; 95% CI, 0.79 to 2.96).  Treatment with vaptans reduced weight (WMD, -1.82 kg; 95% CI, -2.86 to 0.79), time to first paracentesis (RR, 0.76; 95% CI, 0.63 to 0.90), and the clinical severity of ascites (RR, 0.71; 95% CI, 0.60 to 0.83).  Adverse events were more likely with vaptan therapy compared to control (RR, 3.97; 95% CI, 1.78 to 8.83), including an excessive urine volume (RR, 9.96; 95% CI, 1.38 to 71.68). Treatment with vaptans had no effect on SBP and DBP. Treatment with vaptans increased vasopressin and renin levels; however, there is no clear difference between treatments in aldosterone levels.
Torres et al. <sup>24</sup> (2011) TEMPO 3:4  Tolvaptan 45, 60, or 90 mg QAM and 15 or 30 mg QPM  vs  placebo	DB, MC, RCT  Adults 18 to 50 years of age with ADPKD, total kidney volume (TKV) ≥750 mL, CrCl ≥ 60 mL/min	N=1,445  36 months	Primary: Annual rate of percentage change in TKV  Secondary: ADPKD progression as measured by worsening kidney function, significant kidney pain, worsening hypertension, and worsening albuminuria	Primary: Over the three-year period, total kidney volume increased by 2.8% per year (95% CI, 2.5 to 3.1) with tolvaptan versus 5.5% per year (95% CI, 5.1 to 6.0) with placebo. Tolvaptan changed the rate of growth by -2.7 percentage points per year (95% CI, -3.3 to -2.1); the ratio of the geometric means of growth rate was 0.97 (95% CI, 0.97 to 0.98; P<0.001). Tolvaptan changed the rate of growth by -2.7 percentage points per year and a mixed-model repeated-measures analysis confirmed the analysis noting percent change of 9.65% with tolvaptan vs 18.85% with placebo; a difference of -9.2 percentage points (95% CI, -11.1 to -7.3; P<0.001).  Secondary: The relative rate of ADPKD-related events was decreased by 13.5% in tolvaptan treated patients as compared with placebo (44 vs 50 events per 100 person-years (HR, 0.87; 95% CI, 0.78 to 0.97; P<0.01). Effects on worsening kidney function and kidney pain events drove the result of secondary endpoint. Tolvaptan exhibited no effect on hypertension or albuminuria events.
Raina et al. <sup>25</sup> (2021) TEMPO 3:4	Post-hoc analysis of TEMPO 3:4	N=1,445  36 months	Primary: Annual rate of change in TKV	Primary: Over the three year period, TKV in the adolescents and young adults group treated with tolvaptan increased by 3.8% per year (95% CI, 3.8 to

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
Tolvaptan 45, 60, or 90 mg QAM and 15 or 30 mg QPM vs placebo	Adults 18 to 50 years of age with ADPKD, total kidney volume (TKV) $\geq$ 750 mL, CrCl $\geq$ 60 mL/min		after three years in patients aged 18 to 24 years  Secondary: Long-term safety of tolvaptan in patients 18 to 24 years of age by assessing the number of patients who had liver toxicity as defined per Hy's law	5.2) compared to 6.5% per year (95% CI, 4.2 to 8.6) with placebo. Tolvaptan decreased the rate of growth by 2.7 percentage points per year (P=0.0491) compared to placebo and represents a treatment effect of 41.2%.  Secondary: In both the AYA and adult groups, none of the patients met the criteria for Hy's law of hepatotoxicity.
Torres et al. <sup>26</sup> REPRISE  Tolvaptan 45, 60, or 90 mg QAM and 15 or 30 mg QPM vs placebo	DB, MC, RCT  Adults 18 to 55 years of age with ADPKD with eGFR 25 to 65 mL/min or 56 to 65 years of age with eGFR 25 to 44 mL/min	N=1,370  12 months	Primary: Annualized mean change in eGFR from pre-treatment baseline to post-treatment follow-up  Secondary: Mean change in annualized eGFR slope	Primary: The change from baseline in the eGFR was -2.34 ml/min (95% CI, -2.81 to -1.87) in the tolvaptan group, as compared with -3.61 ml/min (95% CI, -4.08 to -3.14) in the placebo group (difference, 1.27 ml/min; 95% CI, 0.86 to 1.68; P<0.001).  Secondary: The difference in mean change in annualized eGFR slope between tolvaptan and placebo was 1.01 mL/min (95% CI, 0.62 to 1.40; P<0.001).

**IX. Cost**

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of '\$' signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 10. Relative Cost of the Vasopressin Antagonists**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost
Tolvaptan	tablet	Jynarque <sup>®</sup> , Samsca <sup>®*</sup>	\$\$\$\$\$	\$\$\$\$\$

N/A=not available

**X. Conclusions**

Tolvaptan (Samsca<sup>®</sup>) is FDA-approved for the treatment of clinically significant euvolemic and hypervolemic hyponatremia (serum sodium <125 mEq/L or less marked hyponatremia that is symptomatic and has resisted correction with fluid restriction), including patients with heart failure and SIADH.<sup>2</sup> The management of hyponatremia depends on the clinical presentation and duration of the disease. Treatment must be approached carefully as overly rapid correction of hyponatremia (>10 to 12 mEq/L per 24 hours) may cause osmotic demyelination.<sup>2,3,6</sup>

There are limited guidelines available that discuss the management of hyponatremia. An expert panel provided treatment recommendations in 2013, which includes fluid restriction, sodium chloride administration, and diuresis. The panel concluded that the current role for vasopressin antagonists in SIADH is in treating mild to moderate hyponatremia and asymptomatic severe hyponatremia. Because there is a paucity of data for patients with severely symptomatic hyponatremia, hypertonic saline remains the treatment of choice in this group until more evidence-based data are available. In patients with heart failure, a vasopressin antagonist is recommended if

serum sodium does not correct to the desired level with hypertonic saline or fluid restriction. The fluid restriction should be lifted before starting these agents.<sup>3</sup>

Three short-term trials evaluating the safety and efficacy of tolvaptan in a relatively small number of patients with euvolemic or hypervolemic hyponatremia demonstrated significant improvements in serum sodium concentrations compared to fluid restriction or placebo.<sup>10,11</sup> An open-label, long-term extension study (mean follow-up of 701 days) assessed the drug-related adverse effects of tolvaptan and maintenance of efficacy, and concluded that prolonged administration of tolvaptan maintained an increased serum sodium level with an acceptable margin of safety.<sup>12</sup> Evidence suggests that hyponatremia recurs after discontinuation of tolvaptan.<sup>12,13</sup> Several other studies have evaluated the use of tolvaptan in patients with congestive heart failure as an add-on to conventional treatments.<sup>14-17,19,21,22</sup> Significant changes in body weight have been observed; however, the long-term use of tolvaptan (median duration 9.9 months) failed to demonstrate any improvements in mortality or hospitalizations for worsening heart failure.<sup>17</sup> A meta-analysis also failed to demonstrate a benefit in mortality with vaptan therapy compared to control in patients with cirrhosis and hyponatremia or ascites.<sup>23</sup>

Data supporting the use of tolvaptan are limited. It has not been established that raising serum sodium with tolvaptan provides a symptomatic benefit to patients. Patients requiring intervention to raise serum sodium urgently should not be treated with tolvaptan. Hospitalization is required for initiation and reinitiation of tolvaptan therapy so that serum sodium can be monitored closely.<sup>2</sup>

Tolvaptan is now also available under the brand name Jynarque<sup>®</sup>, which is indicated to slow kidney function decline in adults at risk of rapidly progressing autosomal dominant polycystic kidney disease (ADPKD).<sup>4</sup> Jynarque<sup>®</sup> is the only FDA-approved treatment for ADPKD. Safety and efficacy were established in two phase III trials, treating almost 3,000 adult patients with early and late stage ADPKD. Tolvaptan slowed the increase in total kidney volume and decreased ADPKD-related events, including deterioration of kidney function and pain, as compared to placebo.<sup>24,25</sup> Guidelines for the use of tolvaptan in ADPKD are limited, but the Updated Canadian Expert Consensus on Assessing Risk of Disease Progression and Pharmacological Management of Autosomal Dominant Polycystic Kidney Disease does suggest using tolvaptan in line with the FDA-approved indication.<sup>9</sup>

There is insufficient evidence to conclude that tolvaptan offers a significant clinical advantage over other alternatives in general use. Since tolvaptan is not indicated as first-line therapy for the management of hyponatremia, it should be managed through the medical justification portion of the prior authorization process.

Therefore, all brand vasopressin antagonists within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

## **XI. Recommendations**

No brand vasopressin antagonist is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

**Alabama Medicaid Agency  
Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Diuretics, Miscellaneous  
AHFS Class 402892  
May 4, 2022**

**I. Overview**

In July 2010, conivaptan and tolvaptan were moved from the miscellaneous diuretics class (AHFS Class 402892) to the vasopressin antagonists class (AHFS Class 402828). Currently, there are no drugs classified by AHFS as miscellaneous diuretics.

**II. Conclusions**

There are no drugs available in the miscellaneous diuretics class (AHFS Class 402892).

**III. Recommendations**

No brand miscellaneous diuretic is recommended for preferred status. Alabama Medicaid should continue to include AHFS Class 402892 in the PDL screening process. If new outpatient miscellaneous diuretics are added, it is recommended that this class be re-reviewed at that time.

Parasympathomimetic (Cholinergic) Agents, AHFS Class 120400  
Central Nervous System Agents, Miscellaneous, AHFS Class 289200  
May 4, 2022**

## I. Overview

Alzheimer's disease is a progressive neurodegenerative disorder in older adults that affects cognition, behavior, and activities of daily living.<sup>1,2</sup> It is the most common form of dementia and the average life expectancy from the onset of symptoms to death is approximately 10 years.<sup>1-3</sup> Diagnostic features include memory impairment and one or more of the following: aphasia, apraxia, agnosia, and/or disturbance in executive functioning.<sup>1</sup>

The pathophysiologic mechanisms are not entirely understood; however, the disease is characterized by the accumulation of intracellular neurofibrillary tangles and extracellular amyloid plaques in various regions of the brain. Inflammation and free radical processes lead to neuron dysfunction and death. It is thought that memory loss is partially the result of a deficiency of cholinergic neurotransmission.<sup>2-3</sup> Glutamate, an excitatory neurotransmitter, may also play a role in the pathophysiology of Alzheimer's disease. Glutamate activates N-methyl-D-aspartate (NMDA) receptors and is involved in learning and memory. However, excessive amounts of glutamate in the brain may lead to excitotoxicity and cell death.<sup>3</sup>

Agents approved for the treatment of dementia of Alzheimer's disease include cholinesterase inhibitors (donepezil, galantamine, and rivastigmine), an NMDA receptor antagonist (memantine), and a combination product (memantine-donepezil).<sup>4-11</sup> Although none of the agents delay the progression of neurodegeneration, they do delay the progression of symptoms. The cholinesterase inhibitors enhance cholinergic function by increasing the concentration of acetylcholine through reversible inhibition of its hydrolysis by acetylcholinesterase. Memantine blocks NMDA receptors and inhibits their overstimulation by glutamate. The combination product containing memantine and donepezil (Namzaric<sup>®</sup>) was launched in May 2015 with the indication for the treatment of moderate to severe dementia of the Alzheimer's type in patients stabilized on 10 mg of donepezil hydrochloride once daily.<sup>11</sup>

Aducanumab-avwa is the first disease modifying therapy approved for the treatment of Alzheimer's disease. Treatment with aducanumab-avwa should be initiated in patients with mild cognitive impairment or mild dementia stage of disease, the population in which treatment was initiated in clinical trials. There are no safety or effectiveness data on initiating treatment at earlier or later stages of the disease than were studied. The efficacy of aducanumab-avwa was evaluated in two double-blind, randomized, placebo-controlled, parallel group studies. Of note, aducanumab received FDA approval based on a surrogate endpoint (reduction in amyloid- $\beta$  plaques) and has not yet been shown to provide a clinical benefit. Aducanumab is a human immunoglobulin (IgG1) monoclonal antibody directed against aggregated soluble and insoluble forms of amyloid- $\beta$ , a defining pathophysiological feature of Alzheimer's disease.<sup>12</sup> None of the other available pharmacologic agents slows or stops the malfunction of neurons that lead to Alzheimer's symptoms, but can be useful for reducing symptoms.<sup>13-17</sup>

The Alzheimer's agents that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. All products with the exception of memantine-donepezil and aducanumab-avwa are available in a generic formulation. This class was last reviewed in November 2020.

**Table 1. Alzheimer's Agents Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
<b>Parasympathomimetic (Cholinergic Agents)</b>			
Donepezil	orally disintegrating tablet, tablet	Aricept <sup>®*</sup>	donepezil, Aricept <sup>®*</sup>
Galantamine	extended-release capsule, solution	Razadyne ER <sup>®*</sup>	galantamine
Rivastigmine	capsule, transdermal patch	Exelon <sup>®*</sup>	rivastigmine
<b>Central Nervous System Agents, Miscellaneous</b>			

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
Aducanumab-avwa	injection	Aduhelm®	none
Memantine	extended-release capsule, solution, tablet	Namenda®*, Namenda XR®*	memantine
<b>Combination Products</b>			
Memantine and donepezil	extended-release capsule	Namzaric®	none

\*Generic is available in at least one dosage form or strength.  
PDL=Preferred Drug List.

## II. Evidence-Based Medicine and Current Treatment Guidelines

Current treatment guidelines that incorporate the use of the Alzheimer's agents are summarized in Table 2.

**Table 2. Treatment Guidelines Using the Alzheimer's Agents**

Clinical Guideline	Recommendation(s)
European Federation of Neurological Societies: <b>Guidelines for the Diagnosis and Management of Alzheimer's Disease (2010)</b> <sup>14</sup>	<ul style="list-style-type: none"> <li>• Patients and caregivers should be provided with education and support.</li> <li>• There is insufficient evidence to support the use of any drugs purely for the primary prevention of dementia. Cholinesterase inhibitors, vitamin E, ginkgo and estrogens should not be used as treatments for those with mild cognitive impairment.</li> <li>• In patients with Alzheimer's disease, treatment with cholinesterase inhibitors (donepezil, galantamine, or rivastigmine) should be considered at the time of diagnosis, taking into account expected therapeutic benefits and potential safety issues. Benefits on cognitive and non-cognitive symptoms have been demonstrated in those with mild, moderate and severe disease. Realistic expectations for treatment effects and potential side effects should be discussed with the patient and caregivers.</li> <li>• In patients with moderate to severe Alzheimer's disease, treatment with memantine should be considered taking into account expected therapeutic benefits and potential safety issues. Benefits on cognitive and noncognitive symptoms are apparent, some non-cognitive symptoms (agitation, delusions) may respond better than others. Realistic expectations for treatment effects and potential side effects should be discussed with the patient and caregivers.</li> <li>• Regular patient follow-up should be an integral part of management.</li> <li>• Aspirin should not be used as a treatment for Alzheimer's disease, though it can be used in those with Alzheimer's disease who also have other indications for its use (e.g. to prevent cardiovascular events).</li> <li>• Vitamin E should not be used as a treatment for Alzheimer's disease.</li> <li>• Currently, there is insufficient evidence to support the use of other agents including, anti-inflammatory drugs, nootropics (including piracetam, nicergoline), selegiline, oestrogens, pentoxifylins, or statins in the treatment or prevention of Alzheimer's disease.</li> <li>• Cognitive stimulation or rehabilitation may be considered in patients with mild to moderate Alzheimer's disease.</li> <li>• Management of behavioral and psychological symptoms of dementia should begin with a careful search for triggers and causative factors (i.e. physical illness). Where possible, initial treatment should be non-pharmacological.</li> <li>• Antipsychotics should only be used for moderate or severe behavioral and psychological symptoms of dementia causing significant distress which have either not responded to other treatments (like non-pharmacological measures or cholinesterase inhibitors) or when other treatments are not appropriate. Low dose of atypical agents should be used only after assessment of risk benefit and full discussion with patient (when capacity allows) and caregiver.</li> <li>• Atypical agents have fewer side effects and do not confer a greater risk of stroke or mortality than conventional drugs.</li> </ul>

Clinical Guideline	Recommendation(s)
National Institute for Health and Care Excellence: <b>Dementia: assessment, management and support for people living with dementia and their carers (2018)</b> <sup>15</sup>	<ul style="list-style-type: none"> <li>• Selective serotonin reuptake inhibitors rather than tricyclic antidepressants should be used to treat depression in Alzheimer's disease.</li> </ul> <p><u>Pharmacological management of Alzheimer's disease</u></p> <ul style="list-style-type: none"> <li>• The three acetylcholinesterase (AChE) inhibitors donepezil, galantamine and rivastigmine as monotherapies are recommended as options for managing mild to moderate Alzheimer's disease.</li> <li>• Memantine monotherapy is recommended as an option for managing Alzheimer's disease for people with:             <ul style="list-style-type: none"> <li>○ moderate Alzheimer's disease who are intolerant of or have a contraindication to AChE inhibitors or</li> <li>○ severe Alzheimer's disease.</li> </ul> </li> <li>• For people with an established diagnosis of Alzheimer's disease who are already taking an AChE inhibitor:             <ul style="list-style-type: none"> <li>○ consider memantine in addition to an AChE inhibitor if they have moderate disease</li> <li>○ offer memantine in addition to an AChE inhibitor if they have severe disease.</li> </ul> </li> <li>• Treatment should be under the following conditions:             <ul style="list-style-type: none"> <li>○ For people who are not taking an AChE inhibitor or memantine, prescribers should only start treatment with these on the advice of a clinician who has the necessary knowledge and skills. This could include:                 <ul style="list-style-type: none"> <li>▪ secondary care medical specialists such as psychiatrists, geriatricians and neurologists</li> <li>▪ other healthcare professionals (such as general practitioners (GPs), nurse consultants and advanced nurse practitioners), if they have specialist expertise in diagnosing and treating Alzheimer's disease.</li> </ul> </li> <li>○ Once a decision has been made to start an AChE inhibitor or memantine, the first prescription may be made in primary care.</li> <li>○ For people with an established diagnosis of Alzheimer's disease who are already taking an AChE inhibitor, primary care prescribers may start treatment with memantine without taking advice from a specialist clinician.</li> <li>○ Do not stop AChE inhibitors in people with Alzheimer's disease because of disease severity alone.</li> </ul> </li> <li>• If prescribing an AChE inhibitor (donepezil, galantamine or rivastigmine), treatment should normally be started with the drug with the lowest acquisition cost (taking into account required daily dose and the price per dose once shared care has started). However, an alternative AChE inhibitor could be prescribed if it is considered appropriate when taking into account adverse event profile, expectations about adherence, medical comorbidity, possibility of drug interactions and dosing profiles.</li> <li>• When using assessment scales to determine the severity of Alzheimer's disease, healthcare professionals should take into account any physical, sensory or learning disabilities, or communication difficulties that could affect the results and make any adjustments they consider appropriate. Healthcare professionals should also be mindful of the need to secure equality of access to treatment for patients from different ethnic groups, in particular those from different cultural backgrounds.</li> <li>• When assessing the severity of Alzheimer's disease and the need for treatment, healthcare professionals should not rely solely on cognition scores in circumstances in which it would be inappropriate to do so. These include:             <ul style="list-style-type: none"> <li>○ if the cognition score is not, or is not by itself, a clinically appropriate tool for assessing the severity of that patient's dementia because of the patient's learning difficulties or other disabilities (for example, sensory impairments), linguistic or other communication difficulties or level of education or</li> </ul> </li> </ul>

Clinical Guideline	Recommendation(s)
	<ul style="list-style-type: none"> <li>○ if it is not possible to apply the tool in a language in which the patient is sufficiently fluent for it to be appropriate for assessing the severity of dementia or</li> <li>○ if there are other similar reasons why using a cognition score, or the score alone, would be inappropriate for assessing the severity of dementia.</li> <li>○ In such cases healthcare professionals should determine the need for initiation or continuation of treatment by using another appropriate method of assessment.</li> </ul> <ul style="list-style-type: none"> <li>● Do not offer the following specifically to slow the progress of Alzheimer's disease, except as part of a randomized controlled trial:           <ul style="list-style-type: none"> <li>○ diabetes medicines</li> <li>○ hypertension medicines</li> <li>○ statins</li> <li>○ non-steroidal anti-inflammatory drugs (NSAIDs), including aspirin.</li> </ul> </li> </ul> <p>Pharmacological management of non-Alzheimer's dementia</p> <ul style="list-style-type: none"> <li>● Offer donepezil or rivastigmine to people with mild to moderate dementia with Lewy bodies.</li> <li>● Only consider galantamine for people with mild to moderate dementia with Lewy bodies if donepezil and rivastigmine are not tolerated.</li> <li>● Consider donepezil or rivastigmine for people with severe dementia with Lewy bodies.</li> <li>● Consider memantine for people with dementia with Lewy bodies if AChE inhibitors are not tolerated or are contraindicated.</li> <li>● Only consider AChE inhibitors or memantine for people with vascular dementia if they have suspected comorbid Alzheimer's disease, Parkinson's disease dementia or dementia with Lewy bodies.</li> <li>● Do not offer AChE inhibitors or memantine to people with frontotemporal dementia.</li> <li>● Do not offer AChE inhibitors or memantine to people with cognitive impairment caused by multiple sclerosis.</li> </ul>
<p>American Academy of Neurology:  <b>Practice Guideline Update Summary: Mild Cognitive Impairment (2018)</b><sup>16</sup></p> <p>Reaffirmed January 30, 2021</p>	<p><u>Pharmacologic treatments for patients diagnosed with mild cognitive impairment (MCI)</u></p> <ul style="list-style-type: none"> <li>● Donepezil use over three years is possibly ineffective for reducing the chances of a progression to possible or probably Alzheimer dementia. In patients with MCI, it is unknown whether donepezil slows progression on various cognitive scales.</li> <li>● Galantamine use over 24 months is probably ineffective for reducing progression to dementia.</li> <li>● Rivastigmine use up to 48 months is possibly ineffective for reducing the rate of progression to possible or probable Alzheimer dementia.</li> </ul> <p><u>Recommendations for management of MCI</u></p> <ul style="list-style-type: none"> <li>● For patients diagnosed with MCI, clinicians should wean patients from medications that can contribute to cognitive impairment (where feasible and medically appropriate) and treat modifiable risk factors that may be contributing.</li> <li>● There are no FDA-approved medications for the treatment of MCI. Moreover, there are no high-quality, long-term studies identifying pharmacologic or dietary agents that either improve cognition or delay progression in patients with MCI. For patients diagnosed with MCI, clinicians should counsel the patients and families that there are no pharmacologic or dietary agents currently shown to have symptomatic cognitive benefit in MCI and that no medications are FDA-approved for this purpose.</li> <li>● Studies of cholinesterase inhibitors showed no benefit on cognitive outcomes or reduction in progression from MCI to dementia, although some studies could not exclude an important effect. In addition to lacking efficacy, side effects of cholinesterase inhibitors are common, including gastrointestinal symptoms and</li> </ul>

Clinical Guideline	Recommendation(s)
	<p>cardiac concerns. For patients diagnosed with MCI, clinicians may choose not to offer cholinesterase inhibitors. If clinicians choose to offer cholinesterase inhibitors, they must first discuss with patients the fact that this is an off-label prescription not currently backed by empirical evidence.</p> <ul style="list-style-type: none"> <li>• For patients diagnosed with MCI who are interested in pharmacologic treatment, clinicians may inform these patients of centers or organizations that can connect patients to clinical trials.</li> <li>• For patients diagnosed with MCI, clinicians should recommend regular exercise (twice per week) as part of an overall approach to management.</li> <li>• In patients with MCI, cognitive interventions may be beneficial in improving measures of cognitive function.</li> </ul>
<p>American College of Physicians/American Academy of Family Physicians:  <b>Current Pharmacologic Treatment of Dementia: A Clinical Practice Guideline (2008)</b><sup>17</sup></p>	<ul style="list-style-type: none"> <li>• The decision to initiate therapy should be based on evaluation of benefits and risks associated with an individual patient. All of the drugs have known adverse events, and the decision to manage patients with dementia should balance harms against modest or even no benefit.</li> <li>• Although the evidence shows statistically significant benefits of treatment with some cholinesterase inhibitors and memantine for all kinds of dementia, these benefits, on average, are not clinically significant for cognition and are modest for global assessments. Currently, there is no way to predict which patients might have a clinically important response. The evidence does not support prescribing these medications for every patient with dementia.</li> <li>• Evidence is insufficient to determine the optimal duration of therapy. No evidence demonstrates when it is appropriate to stop the treatment if the patient becomes unresponsive or shows decline in various domains of dementia. If slowing decline is no longer a goal, treatment with memantine or a cholinesterase inhibitor is no longer appropriate.</li> <li>• The evidence is insufficient to compare the effectiveness of different pharmacologic agents for the treatment of dementia. Because few trials compare one drug with another, evidence about effectiveness is insufficient to support the choice of specific drugs for the treatment of dementia. Assessment of the effectiveness of combination therapy is lacking.</li> <li>• Clinicians should base the choice of pharmacologic agents on tolerability, adverse effect profile and ease of use.</li> </ul>
<p>The Movement Disorder Society:  <b>Evidence-Based Medicine Review Update: Treatments for the non-motor symptoms of Parkinson's disease (2019)</b><sup>18</sup></p>	<p><u>Treatment of dementia in Parkinson's disease</u></p> <ul style="list-style-type: none"> <li>• Rivastigmine is efficacious for the treatment of dementia in Parkinson's disease.</li> <li>• There is insufficient evidence for donepezil and galantamine for the treatment of dementia in Parkinson's disease.</li> <li>• Safety conclusions are that the acetylcholinesterase inhibitors donepezil, rivastigmine, and galantamine have an acceptable risk without specialized monitoring.</li> <li>• The practice implications are that rivastigmine is clinically useful for the treatment of dementia in Parkinson's disease, while the practice implications for donepezil and galantamine are that they are both possibly useful for the treatment of dementia in Parkinson's disease.</li> <li>• The practice implications for memantine are that it is investigational for the treatment of dementia in Parkinson's disease.</li> </ul> <p><u>Treatment of non-dementia cognitive impairment in Parkinson's disease</u></p> <ul style="list-style-type: none"> <li>• There is "insufficient evidence" to conclude on the efficacy of rivastigmine or rasagiline for the treatment of cognitive impairment in Parkinson's disease; practice implications are investigational.</li> </ul>

### III. Indications

The Food and Drug Administration (FDA)-approved indications for the Alzheimer's agents are noted in Table 3. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 3. FDA-Approved Indications for the Single Entity Alzheimer's Agents<sup>4</sup>**

Indication	Parasympathomimetic (Cholinergic Agents)			Central Nervous System Agents, Miscellaneous	
	Donepezil	Galantamine	Rivastigmine	Aducanumab-avwa	Memantine
Mild-to-moderate dementia of the Alzheimer's type		✓	✓ †		
Mild, moderate, and severe dementia of the Alzheimer's type	✓		✓ ‡		
Moderate-to-severe dementia of the Alzheimer's type					✓
Mild-to-moderate dementia associated with Parkinson's disease			✓		
Treatment of Alzheimer's disease in patients with mild cognitive impairment or mild dementia stage of disease				✓	

†Capsule and solution.

‡Transdermal patch.

**Table 4. FDA-Approved Indications for the Combination Product Alzheimer's Agents<sup>4</sup>**

Indication	Memantine and Donepezil
Moderate-to-severe dementia of the Alzheimer's type	✓ *

\*In patients stabilized on 10 mg of donepezil hydrochloride once daily.

### IV. Pharmacokinetics

The pharmacokinetic parameters of the Alzheimer's agents are listed in Table 5. Pharmacokinetic properties of the combination products are in line with the properties of their individual components listed below.

**Table 5. Pharmacokinetic Parameters of the Alzheimer's Agents<sup>5</sup>**

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life
<b>Parasympathomimetic (Cholinergic Agents)</b>					
Donepezil	100	96	Liver (% not reported)	Renal (57) Feces (9 to 15)	70 hours*
Galantamine	90	18	Liver (75)	Renal (95) Feces (5)	7 hours
Rivastigmine	Oral: 36 to 72	40	Liver, extensive Brain, extensive	Renal (>90)	Oral: 1.4 to 1.7 hours Transdermal: 3.0 hours
<b>Central Nervous System Agents, Miscellaneous</b>					
Aducanumab-avwa	Not reported	Not reported	Liver (% not reported)	Not reported	24.8 days
Memantine	Well absorbed	45	Liver, partial	Renal (48)	60 to 80 hours

\* Half-life of 104 hours in subjects over 55 years of age.

## V. Drug Interactions

Major drug interactions with the Alzheimer's agents are listed in Table 6.

**Table 6. Major Drug Interactions with the Alzheimer's Agents<sup>5</sup>**

Generic Name(s)	Interaction	Mechanism
<b>Parasympathomimetic (Cholinergic Agents)</b>		
Donepezil	Azole antifungals	Concomitant use of donepezil, a CYP3A4 substrate that is associated with prolongation of the QT interval, is contraindicated with certain drugs that prolong QT interval and strongly inhibit CYP3A4.
Donepezil	Anticholinergic agents	Concomitant use of a cholinesterase inhibitor, such as donepezil, and an anticholinergic agent may result in interference with the efficacy of both agents.
Donepezil	QT interval prolonging agents	Concurrent use of donepezil and QT interval prolonging agents may result in increased risk of QT-interval prolongation and torsade de pointes.
Donepezil	CYP3A4 inhibitors and inducers	Concurrent use of donepezil and CYP3A4 inhibitors/ inducers may result in increased/decreased donepezil exposure.
Donepezil	Select CYP2D6 inhibitors (clobazam, terbinafine, cinacalcet, peginterferon alfa-2b)	Concurrent use of donepezil and selected CYP2D6 inhibitors may result in increased donepezil exposure.
Donepezil	Seizure threshold lowering agents	Concurrent use of donepezil and seizure threshold lowering agents may result in reduced seizure threshold.
Galantamine	QT interval prolonging agents	Concurrent use of galantamine and QT interval prolonging agents may result in increased risk of QT-interval prolongation and torsade de pointes.
Rivastigmine	Metoclopramide	The concomitant use of metoclopramide and rivastigmine is contraindicated due to potential additive effects of extrapyramidal reactions.
Rivastigmine	Beta blockers	Concomitant use of rivastigmine and beta-blockers, especially cardioselective agents, is not recommended due to additive bradycardic effects resulting in syncope.
<b>Central Nervous System Agents, Miscellaneous</b>		
Memantine	Dextromethorphan, Amantadine, Ketamine	Concurrent use of memantine and selected N-methyl-D-aspartate antagonists may result in increased adverse events of N-methyl-D-aspartate antagonists.
Memantine	Carbonic anhydrase inhibitors	Concurrent use of memantine and carbonic anhydrase inhibitors may result in reduced clearance of memantine due to urinary alkalization.

## VI. Adverse Drug Events

The most common adverse drug events reported with the Alzheimer's agents are listed in Table 7. Adverse drug reactions associated with the combination products are in line with the individual components listed below.<sup>4</sup>

**Table 7. Adverse Drug Events (%) Reported with the Single Entity Alzheimer's Agents<sup>4,6-12</sup>**

Adverse Events	Parasympathomimetic (Cholinergic Agents)			Central Nervous System Agents, Miscellaneous	
	Donepezil	Galantamine	Rivastigmine	Aducanumab-avwa	Memantine

Memantine	<p><u>Moderate-to-severe dementia of the Alzheimer's type:</u>            Solution and tablet: initial, 5 mg once daily, increase dose by 5 mg at weekly intervals (twice daily dosing); maintenance, 10 mg twice daily</p> <p>Extended release capsule: initial, 7 mg once daily; maintenance, 28 mg once daily</p>		Safety and efficacy not established in the pediatric population.	<p>Extended release capsule:            7 mg            14 mg            21 mg            28 mg</p> <p>Extended release capsule dose pack:            7 mg (7 count)-14 mg (7 count)-21 mg (7 count)-28 mg (7 count)</p> <p>Solution:            10 mg/5 mL</p> <p>Tablet:            5 mg            10 mg</p> <p>Tablet dose pack:            5 mg (28 count)-10 mg (21 count)</p>
<b>Combination products</b>				
Memantine and donepezil	<p><u>Moderate-to-severe dementia of the Alzheimer's type:</u>            Extended release capsule: patients stabilized on memantine hydrochloride (10 mg twice daily or 28 mg extended-release once daily) and donepezil hydrochloride 10 mg can be switched to 28 mg-10 mg combination capsule, taken once a day in the evening</p>		Safety and efficacy not established in the pediatric population.	<p>Extended release capsule:            7-10 mg            14-10 mg            21-10 mg            28-10 mg</p> <p>Extended release capsule dose pack:            7-10 mg (7 count)-14-10 mg (7 count)-21-10 mg (7 count)-28-10 mg (7 count)</p>

## VIII. Effectiveness

Clinical studies evaluating the safety and efficacy of the Alzheimer's agents are summarized in Table 9.

**Table 9. Comparative Clinical Trials with the Alzheimer's Agents**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<b>Dementia of Alzheimer's Disease</b>				
Geldmacher et al. <sup>19</sup> (2003)  Donepezil 5 mg/day	OS  Patients with Alzheimer's disease	N=1,115  Variable duration	Primary: Time to nursing home placement  Secondary: Not reported	Primary: Use of donepezil of 5 mg/day or more was associated with significant delays in nursing home placement.  A cumulative dose-response relationship was observed between longer-term sustained donepezil use and delay of nursing home placement.  When donepezil was taken at effective doses for at least nine to 12 months, conservative estimates of the time gained before nursing home placement were 21.4 months for first-dementia-related nursing home placement and 17.5 months for permanent nursing home placement.  Secondary: Not reported
Burns et al. <sup>20</sup> (2007)  Donepezil 5 to 10 mg/day	MC, OL  Patients ≥50 years of age with mild-to-moderate Alzheimer's disease	N=579  132 weeks	Primary: ADAS-cog, CDR-SB, IDDD, QoLS, and adverse events  Secondary: Not reported	Primary: Mean changes in ADAS-cog scores of all patients were improved by approximately two points after six weeks (cumulative week 36) and one point after 12 weeks (cumulative week 42), with improvement compared to the start of OL treatment.  At week 24 (cumulative week 54), mean ADAS-cog scores still showed improvement (approximately 0.5 points) compared to those scores reported at the start of OL treatment. From 24 weeks, ADAS-cog scores declined over the remainder of the study. At the end of 132 weeks of OL treatment (162 weeks total follow-up), the change from DB baseline was 15.6 points for all patients. No difference was seen between patients who had previously received placebo in the DB phase vs those receiving donepezil for the entire treatment period.  CDR-SB scores improved slightly over the first 12 weeks (up to cumulative week 42) of OL treatment and then slowly declined for the

Alzheimer's Agents  
AHFS Classes 120400 and 289200

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>remainder of the study period (up to cumulative week 162).</p> <p>Mean IDDD total scores were maintained over the first 24 weeks of OL treatment to within approximately 1 point relative to those at the beginning of this study period. Mean IDDD scores were 138.1 at week 0, 136.9 at week 12, 138.9 at week 24 and 170.8 at week 132 (162 weeks of total follow-up).</p> <p>At the start of the OL extension, QoLS scores were improved compared to baseline, with a mean change of 3.03. The scores remained above the baseline level at weeks six and 12 of OL treatment. At the end of 132 weeks of OL treatment, the decline from the baseline for the DB study was -46.2.</p> <p>Overall, 85% of patients experienced at least one treatment-emergent adverse event. The most common adverse events included diarrhea (12%), nausea (11%), infection (11%) and accidental injury (10%). Nonfatal all-causality and treatment-related serious adverse events were reported for 25 and 7% of patients, respectively.</p> <p>Seventeen patients died during the study or within four weeks after discontinuation of donepezil. The most common causes of death were pneumonia (seven patients) and cerebrovascular accident (two patients). Fifteen deaths were considered unrelated to donepezil. Two deaths, one due to a cerebral hemorrhage diagnosed on day five of treatment and another due to a suspected myocardial infarction on day 55, were considered by the investigators to be possibly related to donepezil.</p> <p>Secondary: Not reported</p>
<p>Hashimoto et al.<sup>21</sup> (2009)</p> <p>Donepezil 5 mg/day</p>	<p>OS, PRO</p> <p>Patients with Alzheimer's disease</p>	<p>N=416</p> <p>12 weeks</p>	<p>Primary: MMSE</p> <p>Secondary: Not reported</p>	<p>Primary: There were significant changes in mean scores on the MMSE (0.9; P&lt;0.01) from baseline to week 12.</p> <p>There was a significant decrease in the personal strain score at week 12 (P=0.002). There was no significant improvement was in role strain.</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>There was no significant decrease in the time spent supervising Alzheimer's disease patients.</p> <p>Secondary: Not reported</p>
<p>Homma et al.<sup>22</sup> (2009)</p> <p>Donepezil 10 mg/day</p>	<p>OL</p> <p>Japanese patients ≥50 years of age with severe Alzheimer's disease (modified Hachinski Ischemic Score ≤6, FAST ≥6, MMSE score of 1 to 12)</p>	<p>N=189</p> <p>52 weeks</p>	<p>Primary: SIB, and BEHAVE-AD</p> <p>Secondary: Not reported</p>	<p>Primary: The mean change in SIB scores during the OL study showed improvement until week 24, followed by a decline by week 36. For those patients receiving 52 weeks of treatment, the mean change in SIB from baseline (enrollment in OL study) was -6.1. The mean change in SIB declined more rapidly after 24 weeks.</p> <p>For the BEHAVE-AD, little change was observed during the OL study. The change from baseline to week 24 and week 52 was 0.7 and 0.5, respectively. The level of behavioral symptoms in the study population was low.</p> <p>Overall, 177 patients (93.7%) experienced at least one adverse event. Severe adverse events were reported by 15 patients (7.9%) and serious adverse events were reported by 33 patients (17.5%). The most common adverse events were nasopharyngitis, diarrhea, nausea and vomiting.</p> <p>Secondary: Not reported</p>
<p>Courtney et al.<sup>23</sup> (2004)</p> <p>Donepezil 5 to 10 mg/day</p> <p>vs</p> <p>placebo</p>	<p>DB, RCT</p> <p>Patients with Alzheimer's disease</p>	<p>N=565</p> <p>156 weeks</p>	<p>Primary: MMSE, BADLS, time to entering institution</p> <p>Secondary: Not reported</p>	<p>Primary: Cognition averaged 0.8 MMSE points better (95% CI, 0.5 to 1.2; P&lt;0.0001) and functionality 1.0 BADLS points better (95% CI, 0.5 to 1.6; P&lt;0.0001) with donepezil over the first two years.</p> <p>No significant benefits were seen with donepezil compared to placebo in institutionalization (42 vs 44% at three years; P=0.4) or progression of disability (58 vs 59% at three years; P=0.4).</p> <p>The RR of entering institutional care in the donepezil group compared to placebo was 0.97 (95% CI, 0.72 to 1.30; P=0.8); the RR of progression of disability or entering institutional care was 0.96 (95% CI, 0.74 to 1.24; P=0.7).</p>

Alzheimer's Agents  
AHFS Classes 120400 and 289200

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>Similarly, no significant differences were seen between donepezil and placebo in behavioral and psychological symptoms, caregiver psychopathology, adverse events or deaths, or between 5 and 10 mg donepezil.</p> <p>Secondary: Not reported</p>
<p>Sabbagh et al.<sup>24</sup> (2013)</p> <p>Donepezil 23 or 10 mg/day</p>	<p>Post hoc of a 24-week, DB, RCT</p> <p>Patients with moderate to severe Alzheimer's disease (baseline MMSE 0 to 20)</p>	<p>N=</p> <p>Duration not specified</p>	<p>Primary: Cognitive changes in subgroups of patients based on selected baseline and demographic characteristics</p> <p>Secondary: Not reported</p>	<p>Primary: Donepezil 23 mg/day provided statistically significant incremental cognitive benefits over donepezil 10 mg/day irrespective of baseline functional severity, measured by scores on the ADCS-ADL -severe version (P&lt;0.05).</p> <p>When patients were categorized by baseline cognitive severity (MMSE score), significant benefits of donepezil 23 mg/day over 10 mg/day were seen in both subgroups when based on MMSE scores of 0 to 9 vs 10 to 20 (P&lt;0.02 and P&lt;0.01, respectively), and in the more severe subgroup when based on MMSE scores of 0 to 16 vs 17 to 20 (P&lt;0.0001 and P&gt;0.05).</p> <p>Statistically significant incremental cognitive benefits of donepezil 23 mg/day over 10 mg/day were also observed regardless of age, gender, weight, or pre-study donepezil 10mg/day treatment duration (P&lt;0.05).</p> <p>In the multivariate analysis, the only significant interaction was between treatment and baseline MMSE score.</p> <p>Secondary: Not reported</p>
<p>Tariot et al.<sup>25</sup> (2012)</p> <p>Donepezil 23 mg/day</p>	<p>OL</p> <p>Patients with Alzheimer's disease</p>	<p>N=915</p> <p>12 months</p>	<p>Primary: Safety analyses comprised examination of the incidence, severity, and timing of treatment-emergent adverse events;</p>	<p>Primary: In total, 674 patients (74.7%) reported at least one adverse event; in 320 of these patients (47.5%) at least one adverse event was considered to be possibly or probably study drug related.</p> <p>The majority of patients reporting adverse events (81.9%) had adverse events of mild or moderate severity. There were 268 patients (29.7%) who discontinued early, of which 123 (13.6%) were due to adverse events.</p>

			<p>changes in weight, electrocardiogram, vital signs, and laboratory parameters; and discontinuation due to adverse events all at months three, six, nine, and 12</p> <p>Secondary: Not reported</p>	<p>Patients who had increased donepezil dose from 10 mg/day to 23 mg/day had slightly higher rates of adverse events than patients who were already receiving 23 mg (78.0 and 16.9 vs 72.8 and 14.0%, respectively).</p> <p>The incidence of new adverse events declined rapidly after the first two weeks and remained low throughout the duration of the study.</p> <p>Secondary: Not reported</p>
<p>Winblad et al.<sup>26</sup> (2006)</p> <p><u>RCT</u> Donepezil 10 mg/day</p> <p>vs</p> <p>placebo</p> <p><u>OL</u> Donepezil 5 mg daily for 28 days, then 10 mg/day per clinician's judgment</p>	<p>DB, OL, PC</p> <p>Patients 40 to 90 years of age with a probable or possible diagnosis of Alzheimer's disease</p>	<p>N=286</p> <p>52-week RCT with a 2-year OL extension phase</p>	<p>Primary: GBS</p> <p>Secondary: MMSE, GDS, PDS, NPI</p>	<p>Primary: The GBS total scores indicate that both the continuous-treatment group and delayed-start groups had declined, with the difference between the two groups favoring the continuous-donepezil group, over the three-year period (P=0.056).</p> <p>Secondary: The MMSE declined significantly less in the continuous-treatment group than in the delayed-start group over the course of the study (P=0.004, P=0.057, respectively).</p> <p>GDS declined significantly less over the three-year study period in patients in the continuous-treatment group than in those in the delayed-start group (P=0.0231).</p> <p>There was a trend favoring continuous-donepezil treatment over delayed-start treatment on the PDS, although it was not statistically significant (P=0.091).</p> <p>NPI results showed no significant treatment differences between the groups.</p>
<p>Rogers et al.<sup>27</sup> (1998)</p> <p>Donepezil 5</p>	<p>DB, MC, PC, RCT</p> <p>Patients with mild-to-moderate</p>	<p>N=473</p> <p>24 weeks</p>	<p>Primary: ADAS-Cog, CIBIC</p> <p>Secondary:</p>	<p>Primary: Out of 473 patients, 80% of placebo patients, 85% of 5 mg patients and 68% of 10 mg patients completed the study. Those that discontinued due to adverse effects were 7, 6, and 16% in the placebo, 5 and 10 mg groups,</p>

Alzheimer's Agents  
AHFS Classes 120400 and 289200

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
mg/day  vs  donepezil 10 mg/day  vs  placebo	Alzheimer's disease		Not reported	respectively.  Primary outcome measure was mean change in scores from baseline to endpoint in the ADAS-Cog. Both donepezil doses were statistically better than placebo (P<0.0001).  Global functioning as measured by the CIBIC plus were statistically better for both donepezil groups compared to placebo at endpoint (P<0.005).  Donepezil 5 and 10 mg treatment showed no statistical difference in improvements.  Secondary: Not reported
Winblad et al. <sup>28</sup> (2006)  Donepezil 10 mg/day  vs  placebo	DB, PC, PG  Patients ≥50 years of age with severe Alzheimer's disease (MMSE score of 1 to 10 and a FAST rating of stage 5 to 7c)	N=248  6 months	Primary: SIB  Secondary: MMSE, NPI, and CGI-I	Primary: At six months, patients assigned donepezil had significantly better mean change from baseline scores than those taking placebo for SIB (P<0.05).  Secondary: CGI-I scores and the mean change from screening scores on the MMSE at six-month follow-up favored donepezil treatment over placebo (all P<0.05).  There was no significant difference between treatment groups on the NPI for the modified intention-to-treat population (P=0.43).
Black et al. <sup>29</sup> (2007)  Donepezil 10 mg/day  vs  placebo	DB, MC, PC, RCT  Patients ≥50 years of age with severe Alzheimer's disease (MMSE score of 1 to 12, modified Hachinski Ischemic score ≤6, and FAST score ≥6)	N=343  24 weeks	Primary: SIB and CIBIC-Plus  Secondary: ADCS-ADL-sev, NPI, MMSE, CBQ, RUSP	Primary: Donepezil was more efficacious when compared to placebo on SIB score change from baseline to endpoint, as well as on CIBIC-Plus score (P<0.05 for all results).  Secondary: On the ADCS-ADL-sev, both the donepezil group and the placebo group declined from baseline, and the treatment difference was NS (P=0.3574).  On the NPI, donepezil was not significantly different from placebo (P=0.4612).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>The donepezil group showed significant improvement from screening to endpoint on the MMSE compared to placebo (P=0.0267).</p> <p>The CBQ stress measure showed no significant change from baseline for either group.</p> <p>The RUSP scores also had low average responses with little movement from baseline and no significant differences.</p>
<p>Homma et al.<sup>30</sup> (2008)</p> <p>Donepezil 5 to 10 mg/day</p> <p>vs</p> <p>placebo</p>	<p>DB, MC, PC, RCT</p> <p>Japanese patients ≥50 years of age with severe Alzheimer's disease (modified Hachinski Ischemic Score ≤6, FAST ≥6, MMSE score of 1 to 12 and diagnosis confirmed by neuroimaging)</p>	<p>N=302</p> <p>24 weeks</p>	<p>Primary: SIB and CIBIC-Plus</p> <p>Secondary: ADCS-ADL-sev and BEHAVE-AD</p>	<p>Primary: Donepezil 5 and 10 mg/day were more effective than placebo on the SIB. At week 24, patients in the donepezil 5 mg/day group had a significant change from baseline of 2.5 points and those in the donepezil 10 mg/day group had a significant change from baseline of 4.7 points. Patients in the placebo group showed significant worsening (-4.2 points) during the course of the study (P&lt;0.001 vs placebo).</p> <p>For the CIBIC-Plus, the analysis was performed on the seven categories of change as well as the three collapsed categories of improved, no change and worsened. In the seven-category analysis, the distribution of CIBIC-Plus scores in the donepezil 10 mg/day group was better than placebo (P=0.003); however, there was no difference with 5 mg/day (P=0.151). In the collapsed-category analysis, the distribution of CIBIC-Plus scores in the donepezil 10 mg/day group was better than placebo (P=0.001); however, there was no difference with 5 mg/day (P=0.129).</p> <p>Secondary: For the ADCS-ADL-sev, there was no significant differences between donepezil and placebo (placebo group, -1.1 points; donepezil 5 mg/day group, -0.1 points; donepezil 10 mg/day group, -0.3 points).</p> <p>For the BEHAVE-AD, there was no significant differences between donepezil and placebo (placebo group, -0.5; donepezil 5 mg/day group, -0.5; donepezil 10 mg/day group, -0.1).</p> <p>Treatment-emergent adverse events were reported by 73.3% of placebo patients, 78.2% of donepezil 5 mg/day patients and 83.3% of donepezil 10 mg/day patients. There was no significant difference in adverse events</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>between the donepezil groups and the placebo group. The most common adverse events reported are consistent with the known cholinergic side effects of donepezil. Serious adverse events were reported by 15 placebo patients (14.3%), 12 donepezil 5 mg/day patients (11.9%) and 10 donepezil 10 mg/day patients (10.4%).</p> <p>Five patients died during the treatment period. The causes of death were acute pneumonia (placebo group), acute myocardial infarction (donepezil 5 mg/day group), suspected stomach cancer (donepezil 5 mg/day group; the patient died 80 days after discontinuation), vomit-induced tracheal occlusion (donepezil 10 mg/day group; the patient died seven days after completion) and arrhythmia (donepezil 10 mg/day group).</p>
<p>Birks et al.<sup>31</sup> (2006)</p> <p>Donepezil 5 to 10 mg/day</p> <p>vs</p> <p>placebo</p>	<p>MA</p> <p>Patients with Alzheimer's disease</p>	<p>N=5,796 (24 trials)</p> <p>12 to 60 weeks</p>	<p>Primary:            ADAS-Cog, MMSE, CIBIC-Plus, ADL, withdrawals and adverse events</p> <p>Secondary:            Not reported</p>	<p>Primary:</p> <p>A significant difference was seen on the ADAS-Cog scale for patients treated with donepezil 5 mg at 24 weeks (WMD, -2.02 points; 95% CI, -2.77 to -1.26; P&lt;0.00001) and 10 mg at 24 weeks (WMD, -2.81 points; 95% CI, -3.55 to -2.06; P&lt;0.00001).</p> <p>A significant difference was seen on the MMSE for patients treated with donepezil 10 mg/day as compared to placebo at 52 weeks (WMD, 1.84 points; 95% CI, 0.53 to 3.15; P=0.006).</p> <p>Global Clinical State, CIBIC-Plus scores showed significant benefit in patients treated with donepezil 5 and 10 mg/day (OR, 2.38; 95% CI, 1.78 to 3.19; P&lt;0.00001 and OR, 1.82; 95% CI, 1.42 to 2.35; P&lt;0.00001).</p> <p>Improvements were seen in ADL scores for patients in the donepezil group over those in the placebo group (P&lt;0.01 for all scales used).</p> <p>Significantly more patients treated with donepezil 10 mg/day withdrew from treatment (24 vs 20%; P=0.003); however, there was no difference in withdrawal rates between the 5 mg/day and placebo group (P=0.56). Adverse events that occurred significantly more frequently in both the 5 and 10 mg/day treatment groups as compared to placebo are: anorexia, diarrhea, and muscle cramps.</p> <p>Secondary:</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>Wallin et al.<sup>32</sup> (2007)</p> <p>Donepezil 5 to 10 mg/day</p> <p>vs</p> <p>historical data</p>	<p>MC, PRO</p> <p>Patients ≥40 years of age with probable Alzheimer's disease</p>	<p>N=435</p> <p>3 years</p>	<p>Primary: MMSE, ADAS-Cog, CIBIC, IADL</p> <p>Secondary: Not reported</p>	<p>Not reported</p> <p>Primary: For the MMSE, patients had a mean score of 22.0 at baseline and 19.1 at 36 months. After 36 months of donepezil treatment, the mean decline was 3.8 points (95% CI, 3.0 to 4.7).</p> <p>For ADAS-Cog, patients had a mean score of 20.7 at baseline and 26.1 at 36 months. After 36 months, the mean increase was 8.2 points (95% CI, 6.4 to 10.0). A modeling equation predicts an increase in ADAS-Cog to be 4 to 9 points in 12 months without treatment. Scores for the treatment group were significantly better than predicted scores for non-treatment (95% CI, 14.5 to 16.6).</p> <p>For CIBIC, at two months, 34% of patients were considered improved, 59% unchanged and 7% were worse. At six months, 28% of patients were considered improved, 46% unchanged and 26% were worse. At 12 months, 20% of patients were considered improved, 29% unchanged and 51% were worse. At 36 months, 30% of patients were considered improved or unchanged.</p> <p>The IADL change from baseline at six months was 1.01, at 12 months 2.19, and at 36 months 6.18.</p> <p>Secondary: Not reported</p>
<p>Farlow et al.<sup>33</sup> (2010)</p> <p>Donepezil 10 mg/day</p> <p>vs</p> <p>donepezil 23 mg/day</p>	<p>DB, MC, RCT</p> <p>Patients 45 to 90 years of age with moderate-to-severe Alzheimer's disease who took donepezil 10 mg/day ≥12 weeks</p>	<p>N=1,467</p> <p>24 weeks</p>	<p>Primary: Efficacy as measured by SIB-cognition and CIBIC-global function rating; tolerability</p> <p>Secondary: Not reported</p>	<p>Primary: After 24 weeks, the change in SIB-cognition score was significantly greater with donepezil 23 mg/day compared to donepezil 10 mg/day (2.6 vs 0.4, respectively; P&lt;0.001).</p> <p>There was no significant different in CIBIC score with donepezil 23 mg/day compared to donepezil 10 mg/day (4.23 vs 4.29, respectively).</p> <p>In a post-hoc analysis, the least square mean changes in SIB score and CIBIC treatment effect at end point were greater with donepezil 23 mg/day compared to donepezil 10 mg/day in patients with more advanced Alzheimer's disease compared to less impaired patients (SIB, 1.6 vs -1.5,</p>

Raskind et al. <sup>37</sup> (2004)  Galantamine 24 mg/day	OL  Patients with mild-to-moderate Alzheimer's disease	N=194  36 months	Primary: ADAS-Cog, adverse events  Secondary: Not reported	Primary: Patients treated continuously with galantamine for 36 months increased a mean of 10.2±0.9 points on the ADAS-Cog. This was a substantially smaller cognitive decline (approximately 50%) than that predicted for the placebo group.  Patients discontinuing galantamine therapy before 36 months had declined at a similar rate before discontinuation as those completing 36 months of treatment.  Almost 80% of patients who received galantamine for 36 months seemed to demonstrate cognitive benefits compared to those predicted for untreated patients.  Secondary: Not reported
Rockwood et al. <sup>38</sup> (2008)  Galantamine 24 mg/day	MC, OL  Patients with Alzheimer's disease who had received galantamine treatment for up to 36 months	N=240  Up to 48 months	Primary: ADAS-Cog, DAD, adverse events  Secondary: Not reported	Primary: Mean ADAS-Cog worsened from 22.6±8.6 at baseline to 31.3±13.1 at 48 months.  DAD worsened from 73.4±18.1 at baseline to 36.1±29.0 at 48 months.  Fifty one patients withdrew from the study.  Secondary: Not reported
Wallin et al. <sup>39</sup> (2011)  Galantamine 24 mg/day	MC, OL, PRO  Patients with Alzheimer's disease and no previous cholinesterase inhibitor therapy	N=280  36 months	Primary: MMSE, ADAS-cog, IADL, CIBIC  Secondary: Subgroup analysis by K-means cluster analysis	Primary: From baseline to 36 months, MMSE decreased from 23.3 to 21.74. The MMSE score was significantly better at two months (P<0.001) and at six months (P=0.006) compared to baseline, and was stable at 12 months (P=0.616) compared to baseline. The total mean decline in MMSE score from baseline after three years of treatment was 2.6  From baseline to 36 months, ADAS-cog increased from 16.85 to 19.39.

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>The total change in ADAS-cog score after three years of treatment was 5.6 points above baseline values.</p> <p>The ADAS-cog scores at six months were not different from baseline (P=0.248), but deteriorated after that.</p> <p>Mean IADL scores demonstrated deteriorated at all time points compared to baseline (12.76 to 17.13).</p> <p>According to CIBIC scores at two months, 93% of patients remaining in the study were “improved or unchanged”, at months six, 12, 24, and 36; 81, 69, 50, and 41% of the patients were “improved or unchanged”, respectively.</p> <p>Secondary: Cluster analysis identified two response clusters. Cluster 1 included patients with low ability in ADAS-cog and IADL scores at baseline. These patients were older and less educated, but responded better at six months compared to cluster two patients. Cluster 2 patients included better ADAS-cog and IADL scores at baseline. Cluster 2 patients had a higher frequency of the APOE ε4 allele.</p>

vs placebo				Secondary: Not reported
Reisberg et al. <sup>53</sup> (2003)  Memantine 20 mg/day  vs  placebo	DB, PG  Patients with moderate-to-severe Alzheimer's disease	N=252  28 weeks	Primary: CIBIC-Plus and ADCS-ADL  Secondary: SIB	Primary: A significantly greater effect was observed in the memantine group compared to the placebo group on the ADCS-ADL (P=0.03).  There was a significant difference in favor of memantine at week 28 on the CIBIC-Plus using the observed-cases analysis (mean score, 4.7 placebo vs 4.4, memantine; P=0.03), and a numerical difference at study endpoint in favor of memantine using the last-observed-carried-forward analysis (mean score, 4.8 placebo vs 4.5 memantine; P=0.06).  Secondary: Memantine patients showed significantly less cognitive decline on the SIB total score compared to placebo-treated patients over the 28-week study period (P=0.002).
Winblad et al. <sup>54</sup> (1999)  Memantine 10 mg/day  vs  placebo	DB, PC  Patients in Latvia with severe dementia, either Alzheimer's disease or vascular dementia	N=166  12 weeks	Primary: CGI-C and BGP  Secondary: Safety	Primary: Significantly greater improvement was observed in the memantine group compared to the placebo group on the BGP and the CGI-C (P<0.016 and P<0.001, respectively).  Separate analyses of the Alzheimer's disease population alone also yielded statistically significant results in favor of patients receiving memantine, by either the last-observed-carried-forward analysis or the observed-cases analysis on both outcome measures.  At study endpoint, memantine patients showed significantly greater functional improvement compared to patients who received placebo, at study endpoint (P=0.012).  Secondary: No significant differences in safety were found between the groups.
Winblad et al. <sup>55</sup> (2007)  Memantine 20	MA  Four studies: memantine as	N=1,826 in subgroup with moderate-to-	Primary: CIBIC-Plus, SIB, ADAS-Cog, ADCS-ADL, NPI	Primary: There was a statistically significant advantage for the memantine group over the placebo group in all 4 efficacy domains: CIBIC-Plus or global status (P<0.001), SIB or ADAS-Cog status (P<0.001), ADCS-ADL

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
mg/day vs placebo	monotherapy, 2 studies of memantine vs placebo in patients already taking an acetylcholinesterase inhibitor; patients diagnosed with moderate-to-severe Alzheimer's disease	severe Alzheimer's disease  24 to 28 weeks	Secondary: Not reported	(P<0.001) and NPI (P=0.03).  Secondary: Not reported
Wilkinson et al. <sup>56</sup> (2007)  Memantine 20 mg/day  vs  placebo	MA  Patients diagnosed with moderate-to-severe Alzheimer's disease	N=1,826  24 to 28 weeks	Primary: ADAS-Cog, SIB, CIBIC-Pus, ADCS-ADL  Secondary: Not reported	Primary: Significantly more patients in the placebo group (21%) had marked clinical worsening, as demonstrated by deteriorating scores, than in the memantine group (11%; P<0.001).  Significantly more patients in the placebo group (28%) compared to the memantine group (18%) had documentation of worsening in any outcome measure (P<0.001).  Secondary: Not reported
McShane et al. <sup>57</sup> (2006)  Memantine 10 to 30 mg/day  vs  placebo	MA (12 trials)  Patients diagnosed with mild-to-moderate, moderate-to-severe and mild-to-moderate vascular dementia	N=3,731 (15 trials)  Variable duration	Primary: CIBIC-Plus, SIB, ADAS-Cog, ADCS-ADL, NPI  Secondary: Not reported	Primary: Significant improvement at six months was seen for patients with mild-to-moderate dementia treated with memantine on the ADAS-Cog scale (P=0.03); however, there was no significant difference seen for behavior and ADL scales.  Significant improvement at six months was seen for patients with moderate-to-severe dementia treated with memantine for the following scales: CIBIC-Plus (P<0.00001), SIB (P<0.00001), ADCS-ADL (P=0.003) and NPI (P=0.004).  Patients with vascular dementia treated with memantine had significant improvement in cognition scores and behavior scores but no significant change in global rating scales (ADAS-Cog; P=0.0002, NPI; P=0.03).  Secondary:

				Not reported
Grossberg et al. <sup>58</sup> (2013)  Memantine extended-release 28 mg once daily  vs  placebo	DB, MC, RCT  Outpatients with Alzheimer's disease (MMSE scores of three to 14) who were receiving stable, ongoing cholinesterase inhibitor treatment	N=677  24 weeks	Primary: Baseline-to-endpoint score change on the SIB and the endpoint score on the CIBIC-Plus  Secondary: Baseline-to-endpoint score change on the ADCS-ADL19; additional parameters included the baseline-to-endpoint score changes on the NPI and verbal fluency test	Not reported  Primary: At 24 weeks memantine-treated patients significantly outperformed placebo-treated patients on the SIB (2.6; 95% CI, 1.0 to 4.2; P=0.001) and CIBIC-Plus (P=0.008).  Secondary: At 24 weeks memantine-treated patients significantly outperformed placebo-treated patients on the NPI (P=0.005), and verbal fluency test (P=0.004); the effect did not achieve significance on ADCS-ADL19 (P=0.177).  Adverse events with a frequency of >5.0 % that were more prevalent in the memantine group were headache (5.6 vs 5.1 %) and diarrhea (5.0 vs 3.9 %).
Grossberg et al. <sup>59</sup> (2018)  Memantine extended-release 28 mg once daily  vs  placebo	Post-hoc analysis of DB, RCT  Outpatients with Alzheimer's disease (MMSE scores of three to 14) who were receiving stable, ongoing cholinesterase inhibitor (ChEI) treatment	N=677  24 weeks	Primary: Comparing patients receiving memantine ER/ cholinesterase inhibitor (ChEI) to placebo/ChEI for time to onset of response and if the response was maintained (achieving improvement at weeks eight, 12, or 18 and maintaining through	Primary: Greater percentages of memantine ER/ChEI patients achieved an early response that was maintained on SIB, NPI, and CIBIC-Plus (P<0.05) versus placebo/ChEI. Greater percentages of memantine ER/ChEI-treated patients achieved and maintained a clinically notable response on ADL/NPI, SIB/ADL/NPI, and SIB/ADL/CIBIC-Plus, compared with placebo/ChEI (P<0.05). Memantine ER results in early, maintained improvement in patients with moderate to severe Alzheimer's disease concurrently taking ChEIs, compared with cholinesterase treatment alone.  Secondary: When comparing memantine ER/ChEI-treated versus placebo/ChEI-treated responders for all possible combinations of two, three, or four efficacy measures, a greater proportion of memantine ER/ChEI patients showed no decline and clinically notable response versus ChEI alone. The difference between treatments for patients who showed no decline did not

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
			endpoint/week 24)  Secondary: Comparing percentages of patients for all possible combinations of two to four assessments with either no decline or clinically notable response	reach statistical significance; the combination of efficacy outcomes with the greatest difference was SIB/CIBIC-Plus (P=0.0541).
Hager et al. <sup>60</sup> (2016)  Galantamine  vs  placebo  Memantine was taken at baseline and throughout the study by 24.5% of galantamine-treated patients and 24.0% of placebo-treated patients	Post-hoc analysis of DB, PC, PRO, RCT  Patients with mild-to-moderate Alzheimer's disease or mixed dementia stratified by the presence or absence of concomitant memantine	N=2,045  2 years	Primary: Mortality and efficacy parameters including MMSE scores, DAD scores, and nursing home placement  Secondary: Not reported	Primary: In memantine users, mortality rates were not reduced by galantamine (HR, 1.25; 95% CI, 0.63 to 2.46) as they were in nonusers (HR, 0.33; 95% CI, 0.18 to 0.61). Mortality rates in the galantamine-treated groups, compared with placebo, were lower in patient groups with $\geq$ median age and higher MMSE score (18 to 26).  In memantine users, galantamine did not reduce MMSE decline at any time point. In contrast, in memantine nonusers the galantamine group showed reduced decline in MMSE scores as compared with the placebo group at all time points, with a numerical increase in the effect size over time (P>0.05 for all comparisons).  Examination of DAD scores at month 24 demonstrated a benefit in galantamine-treated memantine nonusers, with attenuation of this benefit in the memantine user group across the range of baseline MMSE scores.  In memantine users, the risk of new nursing home admission during year one was higher in the galantamine group than in the placebo group (3.70; 95% CI, 1.04 to 13.23; P=0.03). In memantine nonusers, the risk of nursing home placement tended to be lower in galantamine-treated patients than in placebo-treated patients in year two (RR, 0.19; 95% CI, 0.02 to 1.57; P=0.08). The cumulative numerical percentages of nursing home placements were 5.0% and 18.8% in memantine users on placebo

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				Patients receiving rivastigmine treatment for the entire study (weeks 0 to 52) showed a deterioration of 0.3 points (95% CI, -0.4 to 0.9) on the ADAS-cog at week 52. Those receiving placebo for weeks 0 to 24, followed by the patch, showed a deterioration of 0.9 points [95% CI, -0.4 to 2.1).
Gauthier et al. <sup>70</sup> (2013)  Rivastigmine transdermal patch 4.6 mg/24 hours or 9.5 mg/24 hours, once daily	OS  Patients with Alzheimer's disease with MMSE score of 10 to 26 and GDS score of 4 to 6	N=1,204  18 months	Primary: Change in MMSE from baseline to 18 months  Secondary: Change in MMSE at six and 12 months and change in GDS, assessment of patient ability, overall patient assessment rating, caregiver-reported compliance and treatment satisfaction at six, 12, and 18 months	Primary: Over 18 months of treatment there were no clinically significant changes in MMSE.  Secondary: Over 18 months of treatment there were no clinically significant changes in GDS.  The majority of patients showed improvement or no change in GDS, assessment of patient ability and overall patient assessment rating over 18 months.  The proportion with reported improvement in GDS, assessment of patient ability and overall patient assessment rating was higher than the proportion that deteriorated. Compliance improved from baseline to 18 months and for 88.2% of patient's caregivers preferred the transdermal patch to oral medications.
Sadowsky et al. <sup>71</sup> (2010)  <u>US13 and US18</u> Rivastigmine capsules 3 to 12 mg/day  <u>US38</u> Rivastigmine patch 4.6 mg/24 hours for 5 weeks, then rivastigmine patch	<u>US13 and US18</u> PRO, MC, OL  <u>US38</u> RCT, MC, OL  Patients ≥49 years of age with a diagnosis of dementia of the Alzheimer type (MMSE ≥8 to ≤26 or MMSE >10 to	N=592  25 to 26 weeks	Primary: Safety and tolerability	Primary: In US13 and US18, 67.7% of patients completed the studies and 32.3% of patients withdrew due to adverse events (59.8%), unsatisfactory treatment effect (15.9%), withdrawal of consent (15%), and loss to follow-up (6.5%). The remaining 2.7% of patients discontinued due to protocol deviation, administrative problem, or death.  In US13 and US18, the most frequently reported adverse events (AEs) were nausea (32.9%), vomiting (24.1%), dizziness (11.8%), weight loss (9.1%) agitation (7.9%), fall (7.9%) and confused state (7.9%). Serious AE's were reported in 6% of patients and included pneumonia (1.8%), syncope (1.2%), dehydration (1.2%) and vomiting (1.2%).

Rivastigmine patch 9.5 mg/24 hours  vs  rivastigmine 3 to 12 mg/day	Patients with mild-to-moderate Alzheimer's disease	6 months	Secondary: Strategies followed by a physician to improve adherence and reasons for nonadherence reported by patients	prescribed. At three and six months, 77 and 88.1%, respectively, were noted to be taking more than 80% of their medication as prescribed (P<0.0001 vs baseline). The proportion of adherent patients at three months was 73.6% and at six months was 85.9% (P<0.0001).  Secondary: Modification of Alzheimer's disease treatment was the only intervention that substantially improved adherence at three months (P<0.0001). At the six month visit, psychoeducation was the only effective strategy that reached statistical significance (P<0.0001).  The most common reasons for nonadherence include forgetfulness (56.4%), avoidance of adverse events (30.7%), and refusal of treatment (25.3%).
Boada et al. <sup>75</sup> (2013)  Rivastigmine transdermal patch  vs  rivastigmine capsules	OL  Patients treated with rivastigmine	N=1,078  Duration not specified	Primary: Patient satisfaction (Treatment Satisfaction with Medicines and the Morisky-Green questionnaires)  Secondary: Not reported	Primary: Satisfaction reported was greater with transdermal than oral rivastigmine: mean+standard deviation of the total Treatment Satisfaction with Medicines score, 72.5+14.1 vs 65.2+12.5; P<0.001.  The proportion of adherent patients was greater with transdermal than with oral rivastigmine (65.0 vs 41.4%; P<0.001).  Satisfaction, in turn, was significantly greater in adherent cases than in nonadherent cases.  Secondary: Not reported
Blesa González et al. <sup>76</sup> (2011)  Rivastigmine 6 to 12 mg/day (RO)  vs  rivastigmine patch	MC, OL, RCT  Patients ≥60 years of age with mild-to-moderate Alzheimer's disease who were previously treated with oral rivastigmine	N=142  3 months	Primary: Gastrointestinal adverse events  Secondary: Overall tolerance, local tolerance for those patients on patches, satisfaction level, and cognitive	Primary: Gastrointestinal adverse events were reported in <5% of patients receiving patches (4.7% in RPT and 4.3% in RP) vs 6.1% in RO patients. No statistical significance was reached (P=0.8667). Gastrointestinal adverse events were noted in 11 cases, two in RPT patients, six in RP patients, and three in the RO patients (P=0.3067).  Secondary: Overall tolerability did not reveal any significant differences among the groups (P=0.8239).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
titrated to 9.5 mg/24 hours (RPT)  vs  rivastigmine patch 9.5 mg/24 hours (RP)			state by MMSE	<p>Local tolerability revealed skin or subcutaneous tissue adverse events reported in 11.6% of patients in the RPT group vs 17% of patients in the RP group (P=0.4055). All skin adverse events were reported as slight or moderate intensity.</p> <p>RP was defined by 72% of patients as very easy to use, while RO was considered very easy to use by 30% of patients (P=0.0005). In RP patients, 67% considered it very easy to follow compared to 19% of RO patients (&lt;0.0001). A total of 72% of RP patients confirmed the treatment never interfered with their daily lives vs 40% of the RO group (P=0.0085). Overall satisfaction comparisons revealed that in RP patients, 60% were very satisfied vs 14% in RO patients (P&lt;0.0001).</p> <p>MMSE did not demonstrate significant differences among treatment groups when compared at one and three month visits.</p>
Winblad et al. <sup>77</sup> (2007)  Rivastigmine patch 9.5 mg/24 hours  vs  rivastigmine patch 17.4 mg/24 hours  vs  rivastigmine 12 mg/day  vs  placebo	DD, PC, RCT  Patients 50 to 85 years of age with MMSE scores of 10 to 20 diagnosed with Alzheimer's disease, all patients were required to be living with someone or to be in daily contact with a caregiver	N=1,195  Dose titration in 4-week intervals over 16 weeks and maintained at their highest well-tolerated dose for a further 8 weeks, total of 24 weeks	Primary: ADAS-Cog subscale (assess orientation, memory, language, visuospatial and praxis function), ADCS-CGIC (assess single global rating)  Secondary: ADCS-ADL, MMSE, NPI, Ten Point Clock-drawing Test, and Trail-making Test part A	Primary: Patients in all rivastigmine groups (patch and capsule) showed significant improvements compared to placebo at week 24 with respect to ADAS-Cog and the ADCS-CGIC (all P<0.05 vs placebo).  Secondary: All rivastigmine groups (patch and capsule) showed statistically significant benefits over placebo on the ADCS-ADL, MMSE and Trail-making Test part A (all P<0.05 vs placebo).  Statistically significant treatment effects were not attained on the NPI or Ten Point Clock-drawing Test (P value not reported).

Modrego et al. <sup>87</sup> (2010)  Donepezil 10 mg/day  vs  memantine 20 mg/day	PG, RCT, SB  Patients with mild-to-moderate Alzheimer's disease	N=63  6 months	Primary: ADAS-cog, NPI, DAD, changes in N-acetylaspartate metabolite levels  Secondary: Not reported	Primary: There were no significant differences in the clinical scales with donepezil and memantine (donepezil: ADAS-cog, -0.12; P=NS, NPI, -0.04; P=NS, DAD, 6.67; P=0.014) (memantine: ADAS-cog, -1.37; P=NS, NPI, 1.25; P=NS, DAD, 4.46; P=NS). More patients worsened than improved on either drug.  Daily living activities decreased by 4.4% in the memantine group and 6.6% in the donepezil group (P=0.6).  At baseline, N-acetylaspartate/Cr ratio in the PCG correlated significantly with the ADAS-cog (P=0.02) and MEC (P=0.02). The N-acetylaspartate/Cr ratio correlated with the baseline ADAS-cog (P=0.02) in the left temporal lobe.  At week 24, the PCG was the only area where the correlation was significant. The patients who improved in the ADAS-cog showed increases in the N-acetylaspartate/Cr ratios (P=0.004). None of the baseline metabolite levels predicted response to treatment in any of the examined areas.  Secondary: Not reported
Rozankovic et al. <sup>88</sup> (2021) [Abstract only]  Donepezil  vs  Memantine	OL, RCT  Patients with moderate Alzheimer's disease	N=85  6 months	Primary: NPI at baseline to six months  Secondary: Not reported	Primary: The NPI total score improved from baseline to month six in both groups (P<0.0001).  Analyses of the NPI subdomains revealed that both donepezil treatment and memantine treatment produced statistically significant improvement in all of the NPI domains except euphoria and apathy, for which no improvement was observed after memantine treatment.  Secondary: Not reported

Tariot et al. <sup>91</sup> (2004)  Memantine 20 mg/day  vs  donepezil	DB, MC, PC, RCT  Patients with moderate-to-severe Alzheimer's disease who received stable doses of donepezil	N=404  24 weeks	Primary: SIB, ADCS-ADL, CIBIC-Plus, BGP  Secondary: Not reported	Secondary: Not reported  Primary: A significantly greater therapeutic effect was observed in the memantine group than in the placebo group on the ADCS-ADL, SIB and CIBIC-Plus.  Patients receiving memantine in combination with donepezil demonstrated significantly less decline in ADCS-ADL scores compared to patients receiving donepezil-placebo over the 24-week study period (P=0.02).  Patients receiving memantine showed significantly less cognitive decline in SIB scores compared to patients receiving placebo. Therapy with memantine-donepezil resulted in sustained cognitive performance above baseline compared to the progressive decline seen with the donepezil-placebo treatment.  The change in total mean scores favored memantine vs placebo for the CIBIC-Plus (possible score range was 1-7), 4.41 vs 4.66, respectively (P=0.03).  Treatment discontinuations due to adverse events for memantine vs placebo were 7.4% of the patients compared to 12.4%.  Secondary: Not reported
Bullock et al. <sup>92</sup> (2005)  Rivastigmine 3 to 12 mg/day  vs  donepezil 5 to 10 mg/day	DB, MC, RCT  Patients 50 to 85 years of age with moderate to moderately-severe Alzheimer's disease (MMSE score 10-20)	N=994  24 months	Primary: SIB  Secondary: GDS, ADCS-ADL, MMSE, NPI	Primary: Donepezil-treated patients declined 9.91 points from baseline on the SIB as compared to rivastigmine-treated patients, who declined by 9.30 points (P=NS).  Secondary: Rivastigmine was more effective than donepezil on the ADCS-ADL, on which there was a between-treatment difference of 2.1 points after two years (P=0.007), and greater efficacy on the GDS (P=0.049). There were no significant differences in MMSE and NPI between the treatment groups.

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				More patients receiving rivastigmine reported 'any adverse event' compared to those receiving donepezil during the titration phase (82.0 and 64.7%, respectively). Adverse events were higher with rivastigmine during the titration phase and included nausea (32.9 vs 15.2%) and vomiting (27.9 vs 5.8%). In the maintenance phase, adverse event rates in the two groups were similar (78.7% for the rivastigmine group and 76.9% for the donepezil group). Premature discontinuations due to adverse events were higher in the rivastigmine group during the titration phase (14.1 vs 7.0% for donepezil) but similar in the maintenance phase (17.9 vs 14.1% for donepezil).
Mossello et al. <sup>93</sup> (2004)  Donepezil 5 to 10 mg/day  vs  galantamine 16 to 24 mg/day  vs  rivastigmine 6 to 12 mg/day	OL, OS  Patients with mild-to-moderate Alzheimer's disease	N=407  9 months	Primary: MMSE, ADL and IADL  Secondary: Not reported	Primary: There were no differences amongst the three groups in regard to any of the outcome measures (galantamine was not included in the MMSE comparison due to the small number of treated patients).  Discontinuation due to adverse effects was lower in those patients on donepezil (3%) vs rivastigmine (17%; P=0.01) and vs galantamine (21%; P=0.01).  Secondary: Not reported
Aguglia et al. <sup>94</sup> (2004)  Donepezil  vs  galantamine  vs  rivastigmine	OL  Patients with Alzheimer's disease	N=242  6 months	Primary: MMSE, ADAS-Cog, ADL and IADL  Secondary: Not reported	Primary: There were no statistical differences on changes in the MMSE, ADAS-Cog, ADL or IADL measures amongst the three groups.  There were no differences on changes in the IADL measure among the three groups.  In the ADL measure, donepezil and galantamine patients showed a decrease while there was no change for rivastigmine patients.  Rivastigmine showed a small numerical advantage (but not statistically) compared to donepezil and galantamine on the ADAS-Cog.

<p>Aducanumab low-dose (titrated to target dose of 3 mg/kg for ApoE ε4+ or 6 mg/kg for ApoE ε4-) IV every four weeks</p> <p>vs</p> <p>aducanumab high-dose (titrated to a target dose of 6 mg/kg for ApoE ε4+ or 10 mg/kg for ApoE ε4-) IV every four weeks</p> <p>vs</p> <p>placebo</p>	<p>for MCI due to Alzheimer's disease or mild Alzheimer's disease dementia, with amyloid pathology confirmed by visual assessment of amyloid PET, MMSE score of 24 to 30, and CDR global score of 0.5.</p>		<p>MMSE, ADAS-Cog13, ADCS-ADL-MCI, biomarker endpoints and safety assessments</p>	<p>prespecified futility methodology used pooled data from EMERGE and ENGAGE to predict the future unobserved treatment effect. The individual study results using the prespecified primary efficacy analysis methods on the futility data set showed a -18% treatment difference on the CDR-SB, favoring high-dose aducanumab in EMERGE, and a 15% treatment difference on CDR-SB, favoring placebo in ENGAGE. This refuted an assumption of conditional power (i.e., that the treatment effect in the two studies would be similar), so conditional power was then recalculated using the data from each of the two studies to predict the future unobserved treatment effect, and this non-pooled analysis yielded estimates of 59% and 0% on the primary endpoint for the high-dose groups in EMERGE and ENGAGE, respectively.</p> <p>High-dose aducanumab in EMERGE demonstrated a difference of -0.39 vs placebo in the mean change from baseline in CDR-SB score at week 78 (95% CI, -0.69 to -0.09; P=0.012), a 22% reduction in decline. Results from the low-dose aducanumab arm were not statistically significant compared to placebo on the primary endpoint.</p> <p>In ENGAGE, the difference in mean change from baseline in CDR-SB scores at week 78 was 0.03 with high-dose aducanumab vs placebo (95% CI, -0.26 to 0.33; P=0.833), an increase of 2%. Results from the low-dose aducanumab arm were not statistically significant compared to placebo on the primary endpoint.</p> <p>Secondary:        In EMERGE, the high-dose aducanumab arm also showed less decline vs placebo on each of the three specified secondary endpoints: MMSE (difference of 0.6 vs placebo in mean change from baseline; -18%; P=0.049), ADAS-Cog13 (difference of -1.40 vs placebo in mean change from baseline; -27%; P=0.010), and ADCS-ADL-MCI (difference of 1.7 vs placebo in mean change from baseline; -40%; P&lt;0.001) at week 78.</p> <p>Results from three out of four endpoints from the low-dose aducanumab arm were numerically intermediate between those of the high-dose and placebo arms but not statistically significant vs placebo on any secondary endpoint.</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>In ENGAGE, in the high-dose aducanumab arm, the differences in mean change from baseline at week 78 vs placebo on the MMSE (-0.1; 3%; P=0.811), ADAS-Cog13 (-0.59; -11%; P=0.258), and ADCS-ADL-MCI (0.7; -18%; P=0.151) were not statistically significant. Results from the low-dose aducanumab arm were not statistically significant vs placebo on any of the secondary endpoints and were consistent with those from EMERGE.</p> <p>Amyloid PET substudies assessed 488 and 585 patients in EMERGE and ENGAGE, respectively. These substudies showed a dose- and time-dependent reduction in amyloid PET SUVR in both EMERGE and ENGAGE. At week 78, the difference in adjusted mean change from baseline between high-dose aducanumab and placebo was -0.278 (95% CI, -0.306 to -0.250; P&lt;0.0001) for EMERGE and -0.232 (95% CI, -0.256 to -0.208; P&lt;0.0001) for ENGAGE. For the high-dose aducanumab arm, the reduction in adjusted mean change from baseline in amyloid PET SUVR in ENGAGE was 16.5% less than that in EMERGE at week 78. The adjusted mean changes from baseline in amyloid PET SUVR for low-dose aducanumab arms were similar between EMERGE and ENGAGE at week 78.</p> <p>The incidence of adverse events was similar across dose groups in both studies. Adverse events with an incidence &gt;10% in any dose group were ARIA-E, headache, brain microhemorrhages, nasopharyngitis, fall, localized superficial siderosis and dizziness. The incidence of ARIA-E was higher in the high-dose groups compared with low-dose groups (35% vs 26%, respectively, in EMERGE and 36% vs 26%, respectively, in ENGAGE).</p>
<b>Dementia of Parkinson's Disease</b>				
Emre et al. <sup>109</sup> (2004)  Rivastigmine 3 to 12 mg/day; average dose 8.6 mg/day	DB, MC, PC, RCT  Patients at least 50 years of age with mild-to-moderate dementia developed 2 years after the	N=541  Dose titration over the first 16 weeks with a subsequent	Primary: ADAS-Cog, ADCS-CGIC  Secondary: ADCS-ADL, NPI-10, MMSE, CDR	Primary: Patients who were receiving rivastigmine had significant improvement of 2.1 points in the 70-point ADAS-Cog scores vs worsening of 0.7 point in the placebo group from baseline (P<0.001).  19.8% of patients in the rivastigmine group and 14.5% in the placebo group clinically improved in the ADCS-CGIC scores. 13% of patients in

## Additional Evidence

### Dose Simplification

A search of Medline and PubMed did not reveal data pertinent to this topic.

### Stable Therapy

The cholinesterase inhibitors exhibit similar pharmacologic properties, and evidence from comparative studies support a switch strategy when patients are intolerant to one drug or when a therapeutic dose cannot be reached.<sup>115</sup> Gauthier et al. reported that when switched from donepezil to rivastigmine, approximately 50% of those who had adverse events or a lack of efficacy with donepezil tolerated or responded well to rivastigmine.<sup>116</sup> Wilkinson et al. found no difference in tolerability when patients were switched from donepezil to galantamine using either a four-day washout period or a seven-day washout period.<sup>117</sup> Sadowsky et al. evaluated immediate switch (no washout) or delayed switch (seven-day washout) from oral donepezil to transdermal rivastigmine following a four-week treatment period with donepezil.<sup>118</sup> The authors found that the rates of discontinuation due to any reason or adverse events were similar between the treatment groups. They concluded that both switch strategies were safe and well tolerated. Sakka et al. evaluated patients with moderate-to-severe Alzheimer's disease who were switched to donepezil after experiencing a treatment failure or intolerance with memantine.<sup>119</sup> The authors concluded that donepezil was effective and well tolerated in patients who discontinued memantine monotherapy, including those patients with previous exposure to cholinesterase inhibitors. A post-hoc analysis of five-month trial data with galantamine demonstrated that patients had similar efficacy outcomes, whether or not they had received prior anticholinesterase therapy, suggesting that a previous failure did not predict response to galantamine.<sup>120</sup>

### Impact on Physician Visits

Fillenbaum et al. evaluated the frequency of outpatient visits for patients with Alzheimer's disease.<sup>121</sup> Outpatient visit ranged from 81 to 95% and was not related to the stage of dementia or institutional status. Leibson et al. demonstrated that the onset of Alzheimer's disease is not associated with greater use of acute care services, nor is the high use of nursing home care offset by fewer emergency room or hospital encounters.<sup>122</sup> Clark et al. evaluated a telephone intervention program where healthcare professionals work with patients and caregivers to determine resources within the family of an Alzheimer's patient.<sup>123</sup> Alzheimer's patients in the program felt less embarrassed and isolated because of their memory problems and reported less problems coping with their disease. Intervention patients with more severe impairment had fewer physician visits, were less likely to have an emergency room visit or hospital admission, and had decreased depression and strain. Wimo et al. demonstrated that the use of memantine in patients with moderate-to-severe Alzheimer's disease was associated with less total caregiver time compared to placebo.<sup>124</sup> There were also fewer patients institutionalized at week 28 in the memantine group compared to placebo.

## IX. Cost

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of '\$' signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For brand or generic products with little or no recent utilization data, the average cost per prescription is calculated by using the Alabama Medicaid average acquisition cost (AAC) and the standard daily dosing per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 10. Relative Cost of the Alzheimer's Agents**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost

\*Generic is available in at least one dosage form or strength.  
 N/A=Not available.

## X. Conclusions

The cholinesterase inhibitors are approved for the treatment of mild-to-moderate Alzheimer's disease. Donepezil is also approved for the treatment of severe disease. The N-Methyl-D-aspartate (NMDA) receptor antagonist, memantine, has only been approved for the treatment of moderate-to-severe Alzheimer's disease. Although these agents provide symptomatic benefit, they have not been shown to delay the progression of neurodegeneration. Aducanumab-avwa is an amyloid beta-directed antibody and is the first disease modifying therapy approved for the treatment of Alzheimer's disease. Aducanumab received FDA approval based on a surrogate endpoint (reduction in amyloid-β plaques) and has not yet been shown to provide a clinical benefit. All products with the exception of memantine-donepezil and aducanumab-avwa are available in a generic formulation.

There are several guidelines which discuss the role of these agents in the management of Alzheimer's disease.<sup>14-18</sup> The primary goal of treatment is to delay the progression of symptoms and preserve functional ability. The use of a cholinesterase inhibitor may lead to modest improvements in some patients; therefore, it is appropriate to offer a trial of one of these agents for patients with mild-to-moderate disease.<sup>17</sup> In patients with Alzheimer's disease, treatment with cholinesterase inhibitors (donepezil, galantamine, or rivastigmine) should be considered at the time of diagnosis, taking into account expected therapeutic benefits and potential safety issues. In patients with moderate to severe Alzheimer's disease, treatment with memantine should be considered taking into account expected therapeutic benefits and potential safety issues.<sup>14-15</sup> Guidelines do not give preference to one agent over another and have not been updated to include the place in therapy for aducanumab-avwa. Clinicians should base the treatment decision on tolerability, adverse events, and ease of use.<sup>14-18</sup>

Numerous clinical trials have evaluated the efficacy and safety of the cholinesterase inhibitors and memantine. Several outcomes have been assessed (using more than 40 different instruments), including cognition, global function, behavior, and quality of life. There is consistent evidence from well-designed studies that donepezil, galantamine, rivastigmine, and memantine positively affect cognition and global function, although the improvements are modest. The findings are less consistent for other outcomes, including behavior and quality of life. In most cases, the duration of these clinical trials was less than one year. Thus, there is insufficient evidence to determine the optimal duration of therapy.<sup>15</sup>

Two randomized clinical trials, EMERGE and ENGAGE, evaluated the efficacy of aducanumab in patients with confirmed presence of amyloid pathology based on positron emission tomography (PET) scan who met clinical criteria for mild cognitive impairment due to Alzheimer's disease or mild Alzheimer's disease dementia. Both studies were terminated early after an interim analysis for futility, which occurred when approximately 50% of the pooled patients in both studies completed week 78. The primary endpoint of change from baseline to week 78 on the CDR-SB, an integrated scale that assesses both function and cognition, was met in EMERGE but not in

ENGAGE. Amyloid PET substudies showed a dose- and time-dependent reduction in amyloid PET standardized uptake value ratio in both studies. The high-dose aducanumab group in EMERGE demonstrated a difference of -0.39 vs placebo in the mean change from baseline in CDR-SB score at week 78 (95% CI, -0.69 to -0.09; P=0.012), a 22% reduction in decline. Results from the low-dose aducanumab arm were not statistically significant compared to placebo on this same measure. In ENGAGE, the difference in mean change from baseline in CDR-SB scores at week 78 was 0.03 with high-dose aducanumab vs placebo (95% CI, -0.26 to 0.33; P=0.833), an increase of 2%. Results from the low-dose aducanumab arm were not statistically significant compared to placebo on the same measure.<sup>108</sup> There are relatively few studies that directly compare the efficacy and safety of the Alzheimer's agents. Most of the trials have compared active treatment to placebo or no treatment. The studies also differ with regards to design, patient population, and treatment duration, which make it difficult to directly compare the results.<sup>19-114</sup>

The Centers for Medicare & Medicaid Services (CMS) completed further evaluation of aducanumab (Aduhelm<sup>®</sup>), including stakeholder input. After extensive evaluation and review due to the limited clinical efficacy outcomes data, beyond that seen with surrogate marker evaluation, compared to placebo in clinical trials and the significant safety concerns, CMS published the final national coverage determination for aducanumab (Aduhelm<sup>®</sup>) on April 7, 2022. The final Medicare national coverage determination indicates coverage of FDA-approved monoclonal antibody therapies directed against amyloid for the treatment of Alzheimer's disease when provided in accordance with the extensive coverage criteria outlined for coverage with evidence development for patients who have a clinical diagnosis of mild cognitive impairment due to Alzheimer's disease or mild Alzheimer's disease dementia, both with confirmed presence of amyloid beta pathology consistent with Alzheimer's disease. The guidance indicates that monoclonal antibodies directed against amyloid that are approved by FDA for the treatment of Alzheimer's disease based upon evidence of efficacy from a change in a surrogate endpoint (e.g., amyloid reduction), considered as reasonably likely to predict clinical benefit, may be covered in a randomized controlled trial conducted under an investigational new drug application. Additionally, monoclonal antibodies directed against amyloid that are approved by FDA for the treatment of Alzheimer's disease based upon evidence of efficacy from a direct measure of clinical benefit may be covered in CMS-approved prospective comparative studies, that meet specific protocol and analysis requirements outlined by CMS.<sup>125</sup>

There is insufficient evidence to support that one brand Alzheimer's agent is safer or more efficacious than another. Formulations without a generic alternative should be managed through the medical justification portion of the prior authorization process.

Therefore, all brand Alzheimer's agents within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

## **XI. Recommendations**

No brand Alzheimer's agent is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

Aducanumab-avwa should not be placed in preferred status regardless of cost.
