

**Alabama Medicaid Agency  
Pharmacy and Therapeutics Committee Meeting  
Clinical Packet  
May 4, 2022**

**Table of Contents**

<b>Helpful Hints/Reference Document</b> .....	2
<b>External Criteria</b>	
Antihypertensive Agents.....	4
Alzheimer’s Agents .....	4
<b>Agenda</b> .....	6
<b>Pharmacotherapy Class Re-Reviews</b>	
Pharmacotherapy Review of Central Alpha-Agonists.....	7
Pharmacotherapy Review of Direct Vasodilators.....	43
Pharmacotherapy Review of Peripheral Adrenergic Inhibitors .....	90
Pharmacotherapy Review of Hypotensive Agents, Miscellaneous .....	91
Pharmacotherapy Review of Alpha-Adrenergic Blocking Agents.....	96
Pharmacotherapy Review of Beta-Adrenergic Blocking Agents .....	165
Pharmacotherapy Review of Dihydropyridines.....	336
Pharmacotherapy Review of Calcium-Channel Blocking Agents, Miscellaneous.....	468
Pharmacotherapy Review of Angiotensin-Converting Enzyme Inhibitors .....	542
Pharmacotherapy Review of Angiotensin II Receptor Antagonists .....	677
Pharmacotherapy Review of Mineralocorticoid (Aldosterone) Receptor Antagonists .....	827
Pharmacotherapy Review of Renin Inhibitors.....	922
Pharmacotherapy Review of Loop Diuretics .....	983
Pharmacotherapy Review of Potassium-Sparing Diuretics .....	1036
Pharmacotherapy Review of Thiazide Diuretics .....	1083
Pharmacotherapy Review of Thiazide-Like Diuretics.....	1158
Pharmacotherapy Review of Vasopressin Antagonists .....	1208
Pharmacotherapy Review of Diuretics, Miscellaneous .....	1234
Pharmacotherapy Review of Alzheimer’s Agents.....	1235

**Pharmacy and Therapeutics (P&T) Committee**  
**Helpful Hints/Reference Document**  
**P&T Charge**

As defined by §22-6-122

The Medicaid Pharmacy and Therapeutics (P&T) Committee shall review and recommend classes of drugs to the Medicaid Commissioner for inclusion in the Medicaid Preferred Drug Plan. Class means a therapeutic group of pharmaceutical agents approved by the FDA as defined by the American Hospital Formulary Service.

The P&T Committee shall develop its preferred drug list recommendations by considering the clinical efficacy, safety and cost effectiveness of a product. Within each covered class, the Committee shall review and recommend drugs to the Medicaid Commissioner for inclusion on a preferred drug list. Medicaid should strive to insure any restriction on pharmaceutical use does not increase overall health care costs to Medicaid.

The recommendations of the P&T Committee regarding any limitations to be imposed on any drug or its use for a specific indication shall be based on sound clinical evidence found in labeling, drug compendia and peer reviewed clinical literature pertaining to use of the drug. Recommendations shall be based upon use in the general population. Medicaid shall make provisions in the prior approval criteria for approval of non-preferred drugs that address needs of sub-populations among Medicaid beneficiaries. The clinical basis for recommendations regarding the PDL shall be made available through a written report that is publicly available. If the recommendation of the P&T Committee is contrary to prevailing clinical evidence found in labeling, drug compendia and/or peer-reviewed literature, such recommendation shall be justified in writing.

**Preferred Drug List/Program Definitions**

**Preferred Drug:** Listed on the Agency's Preferred Drug Lists and will not require a prior authorization (PA).

**Preferred with Clinical Criteria:** Listed on the Agency's Preferred Drug Lists but will require a prior authorization. Clinical criteria must be met in order to be approved.

**Non Preferred Drug:** Covered by the Agency, if it is determined and supported by medical records to be medically necessary, but will require a PA.

**Non Covered Drug:** In accordance with Medicaid Drug Amendments contained in the Omnibus Budget Reconciliation Act of 1990 (OBRA 90 federal legislation), the Agency has the option to not cover (or pay for) some drugs. Alabama Medicaid does not cover/pay for the following:

- Drugs used for anorexia, weight loss or weight gain, with the exception of those specified by the Alabama Medicaid Agency
- Drugs used to promote fertility with the exception of those specified by the Alabama Medicaid Agency
- Drugs used for cosmetic purposes or hair growth
- Over-the-counter/non prescription drugs, with the exception of those specified by the Alabama Medicaid Agency
- Covered outpatient drugs when the manufacturer requires as a condition of sale that associated test and/or monitoring services be purchased exclusively from the manufacturer or designee
  - DESI (Drug Efficacy Study Implementation [less than effective drugs identified by the FDA]) and IRS (Identical, Related and Similar [drugs removed from the market]) drugs which may be restricted in accordance with Section 1927(d) (2) of the Social Security Act
  - Agents when used for the symptomatic relief of cough and colds except for those specified by the Alabama Medicaid Agency
  - Prescription vitamin and mineral products, except prenatal vitamins and fluoride preparations and others as specified by the Alabama Medicaid Agency
  - Agents when used for the treatment of sexual or erectile dysfunction, unless authorized for pulmonary hypertension.

(From Alabama Medicaid Agency Administrative Code, Chapter 16 and Alabama Medicaid Agency Provider Billing Manual, Chapter 27.)

**Prior Authorization (PA):** Process that allows drugs that require approval prior to payment to be reimbursed for an individual patient. Drugs may require PA if they are preferred with clinical criteria, are non-preferred status, or if they required PA prior to the PDL.

Medicaid may require prior authorization for generic drugs only in instances when the cost of the generic product is significantly greater than the net cost of the brand product in the same AHFS therapeutic class or when there is a clinical concern regarding safety, overuse or abuse of the product.

Although a product may require PA, the product is considered a covered product and Medicaid will pay for the product only once the PA has been approved.

**Override:** Process where drugs require approval prior to payment to be reimbursed for an individual patient if the claim falls outside a predetermined limit or criteria. Overrides differ from PA in that drugs or drug classes that require an override will automatically allow payment of the drug unless something on the claim hits a predetermined limit or criteria. The different types of overrides include:

- Accumulation Edit
- Brand Limit Switchover
- Dispense As Written Override
- Early Refill
- Ingredient Duplication
- Maintenance Supply Opt Out
- Maximum Unit/Max Cost Limitations
- Short Acting Opioid Naïve Override
- Therapeutic Duplication

**Electronic PA (EPA):** The EPA system checks patient-specific claims history to determine if pharmacy and medical PA requirements are met at the Point-of-Sale claim submission for a non-preferred drug. If it is determined that all criteria are met and the request is approved, the claim will pay and no manual PA request will be required. Electronic PA results in a reduction in workload for providers because the claim is electronically approved within a matter of seconds with no manual PA required.

#### **Prior Authorization Criteria Definitions**

**Appropriate Diagnosis:** Diagnosis(es) that justifies the need for the drug requested. Diagnosis(es) or ICD-10 code(s) may be used. Use of ICD-10 codes provides specificity and legibility and will usually expedite review.

**Prior Treatment Trials:** Prior authorization requires that two (2) prescribed generic, OTC or brand name drugs have been utilized unsuccessfully relative to efficacy and/or safety within six (6) months prior to requesting the PA. The PA request must indicate that two (2) generic, OTC or other brand drugs have been utilized for a period of at least thirty (30) days each (14 days for Triptans, 3 days for EENT Vasoconstrictor Agents), **unless** there is an adverse/allergic response or contraindication. If the prescribing practitioner feels there is a medical reason for which the patient should not be on a generic, OTC or brand drug or drug trial, medical justification may be submitted in lieu of previous drug therapy. One prior therapy is acceptable in those instances when a class has only one preferred agent, either generic, OTC, or brand.

**Stable Therapy:** Allows for approval of a PA for patients who have been determined to be stable on a medication (same drug, same strength) for a specified timeframe and who continue to require therapy. Medications paid for through insurance, private pay or Medicaid are also counted toward the requirement. Providers will be required to document this information on the PA request form and note the program or method through which the medication was dispensed.

**Medical Justification:** An explanation of the reason the drug is required and any additional information necessary. Medical justification is documentation to support the physician's choice of the requested course of treatment. Documentation from the patient record (history and physical, tests, past or current medication/treatments, patient's response to treatment, etc) illustrates and supports the physician's request for the drug specified. For example, if a recommended therapy trial is contraindicated by the patient's condition or a history of allergy to a first-line drug, and the physician wants to order a non-preferred drug, documentation from the patient record would support that decision. In addition, medical justification may include peer reviewed literature to support the use of a non-preferred medication.

## **External Criteria**

### **Antihypertensive Agents**

#### **Appropriate Diagnosis**

- The patient must have an appropriate diagnosis supported by documentation in the patient record.

#### **Prior Treatment Trials**

- The patient must also have failed 30-day treatment trials with at least two prescribed and preferred antihypertensive agents in this class, either generic, OTC, or brand, within the past 6 months or have a documented allergy or contraindication to all preferred agents in this class.
- To meet these prior usage requirements, drugs within this specific classification must be judged against others in the same class (AHFS specific). For example, to qualify for a non-preferred beta-blocker, the patient must have met prior usage requirements of 30-day treatment trials with two other preferred beta-blockers, either generic, OTC, or brand.
- For fixed-dose combination products containing drugs from 2 or more different subclasses, prior therapies must include at least 2 prescribed and preferred agents from the respective subclasses.
- For BiDil<sup>®</sup>, in lieu of prior usage requirements, approval may be obtained for adjunctive therapy to standard heart failure therapy (including a diuretic, angiotensin converting enzyme inhibitor or angiotensin II receptor antagonist, and beta-blocker) in self-identified black patients.
- For Hemangeol<sup>®</sup>, patients must be five weeks to five months of age when initiating treatment. Hemangeol<sup>®</sup> may only be approved for the treatment of proliferating infantile hemangioma requiring systemic therapy.
- For Jynarque<sup>®</sup>, patients must have documented ALT, AST and bilirubin values before initiating treatment. Jynarque<sup>®</sup> may only be approved to slow kidney function decline in adults at risk of rapidly progressing autosomal dominant polycystic kidney disease.
- For Samsca<sup>®</sup>, patients must have a documented serum sodium <125 mEq/L, or less marked hyponatremia that is symptomatic and has resisted correction with fluid restriction. Patients must also have documentation of being initiated on Samsca<sup>®</sup> in an inpatient setting.

#### **Stable Therapy**

- Approval may be given for those who have documented stable therapy on the requested medication for 60 consecutive days or greater.

#### **Medical Justification**

- Medical justification may include peer reviewed literature, medical record documentation, or other information specifically requested.

#### **PA Approval Timeframes**

- Approval may be given for up to 12 months.

#### **Electronic Prior Authorization (EPA)**

- Antihypertensive agents are included in the electronic PA program.

#### **Verbal PA Requests**

- Not Applicable

## **Alzheimer's Agents**

### **Appropriate Diagnosis**

- The patient must have an appropriate diagnosis supported by documentation in the patient record.

### **Prior Treatment Trials**

- The patient must also have failed 30-day treatment trials with at least one other prescribed and preferred Alzheimer's agent in this class, either generic, OTC, or brand, within the past 6 months, or have a documented allergy or contraindication to all preferred agents in this class.

### **Stable Therapy**

- Stable therapy for this class is defined as a 90-day or greater timeframe. Approval may be given for those who have documented stable therapy on the requested medication for 90 consecutive days or greater.

### **Medical Justification**

- Medical justification may include peer-reviewed literature, medical record documentation, or other information specifically requested.

### **PA Approval Timeframes**

- Approval may be given for up to 12 months.

### **Electronic Prior Authorization (EPA)**

- Alzheimer's agents are included in the electronic PA program.

### **Verbal PA Requests**

- PA requests that meet prior usage requirement for approval may be accepted verbally.

# AGENDA

## ALABAMA MEDICAID AGENCY PHARMACY AND THERAPEUTICS (P&T) COMMITTEE

May 4, 2022  
1:00 p.m. – 3:00 p.m.

- 
1. Opening remarks.....Chair
  2. Approval of February 9, 2022 P&T Committee Meeting minutes.....Chair
  3. Pharmacy program update.....Alabama Medicaid
  4. Oral presentations by manufacturers/manufacturers' representatives  
(prior to each respective class review)
  5. Pharmacotherapy class re-reviews.....University of Massachusetts Clinical Pharmacy Services
    - Mineralocorticoid (Aldosterone) Receptor Antagonists – AHFS 243220
    - Central Alpha-Agonists – AHFS 240816
    - Direct Vasodilators – AHFS 240820
    - Peripheral Adrenergic Inhibitors – AHFS 240832
    - Hypotensive Agents, Miscellaneous – AHFS 240892
    - Alpha-Adrenergic Blocking Agents – AHFS 242000
    - Beta-Adrenergic Blocking Agents – AHFS 242400
    - Dihydropyridines – AHFS 242808
    - Calcium-Channel Blocking Agents, Miscellaneous – AHFS 242892
    - Angiotensin-Converting Enzyme Inhibitors – AHFS 243204
    - Angiotensin II Receptor Antagonists – AHFS 243208
    - Renin Inhibitors – AHFS 243240
    - Loop Diuretics – AHFS 402808
    - Potassium-Sparing Diuretics – AHFS 402816
    - Thiazide Diuretics – AHFS 402820
    - Thiazide-Like Diuretics – AHFS 402824
    - Vasopressin Antagonists – AHFS 402828
    - Diuretics, Miscellaneous – AHFS 402892
    - Alzheimer's Agents
      - *Parasympathomimetic (Cholinergic) Agents – AHFS Class 120400 (current brands to be included: Aricept®, Exelon®, and Razadyne® ER only)*
      - *Central Nervous System Agents, Miscellaneous – AHFS Class 289200 (current brands to be included: Aduhelm®, Namenda®, Namenda® XR, and Namzaric® only)*
  6. New business
  7. Results of voting announced.....Chair
  8. Next meeting dates
    - August 10, 2022
    - November 9, 2022
    - February 8, 2023
    - May 3, 2023
  9. Adjourn

**Alabama Medicaid Agency  
Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Central Alpha-Agonists  
AHFS Class 240816  
May 4, 2022**

**I. Overview**

Drugs to treat hypertension are among the most frequently prescribed pharmacologic agents. The incidence of hypertension increases with age, and the proper selection of an antihypertensive agent is an important issue.<sup>1,2</sup> While a multitude of neurohormonal, renal, and vascular mechanisms have been proposed as contributors to hypertension, no specific cause can be assigned in most cases.<sup>3,4</sup> Antihypertensive agents are separated into broad classes depending on which aspect of blood pressure regulation they affect: sodium and water balance, the sympathetic nervous system, resistance from vascular smooth muscle, or the renin-angiotensin-aldosterone system (RAAS).<sup>5</sup> Most patients will require therapy with more than one agent to achieve adequate blood pressure control. When monotherapy fails to achieve the blood pressure goal, then a second agent from a different class should be added to the treatment regimen.<sup>1</sup>

The central alpha-agonists are approved for the treatment of hypertension. They lower blood pressure primarily through stimulation of  $\alpha_2$ -adrenergic receptors in the central nervous system (CNS). This action inhibits sympathetic vasomotor centers, causing decreased sympathetic outflow from the CNS and an associated increase in vagal tone. Sympathetic activity is reduced while parasympathetic activity is increased. This leads to a reduction in total peripheral resistance, systolic and diastolic blood pressure, baroreceptor reflexes, heart rate, and cardiac output.<sup>3,6-10</sup> Plasma renin activity is also affected by the central  $\alpha$ -agonists, but the relationship between this and their hypotensive effects has not been fully elucidated. Chronic central  $\alpha$ -agonist use is associated with sodium and fluid retention, which may require concomitant diuretic therapy.<sup>3</sup> Methyldopa is available in combination with a thiazide diuretic. Thiazide diuretics inhibit the reabsorption of sodium and chloride in the cortical thick ascending limb of the loop of Henle and the early distal tubules. This action leads to an increase in the urinary excretion of sodium and chloride.<sup>6-10</sup>

The central  $\alpha$ -agonists that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. All of the products are available in a generic formulation. This class was last reviewed in February 2020.

**Table 1. Central Alpha-Agonists Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
<b>Single Entity Agents</b>			
Clonidine	tablet, transdermal patch	Catapres-TTS®*	clonidine, Catapres-TTS®*
Guanfacine	tablet	N/A	guanfacine
Methyldopa	tablet	N/A	methyldopa
Methyldopate	injection^	N/A	methyldopate

\*Generic is available in at least one dosage form or strength.

^Product is primarily administered in an institution.

PDL=Preferred Drug List

N/A=Not available

## II. Evidence-Based Medicine and Current Treatment Guidelines

Current treatment guidelines that incorporate the use of the central  $\alpha$ -agonists are summarized in Table 2.

**Table 2. Treatment Guidelines Using the Central Alpha-Agonists**

Clinical Guideline	Recommendations
<p>Eighth Joint National Committee (JNC 8): <b>2014 Evidence-based Guideline for the Management of High Blood Pressure in Adults (2014)<sup>1</sup></b></p>	<ul style="list-style-type: none"> <li>• Pharmacologic treatment should be initiated in patients <math>\geq 60</math> years of age to lower blood pressure at systolic blood pressure <math>\geq 150</math> mm Hg or diastolic blood pressure <math>\geq 90</math> mm Hg and to a goal systolic blood pressure <math>&lt; 150</math> mm Hg and goal diastolic blood pressure <math>&lt; 90</math> mm Hg. Adjustment of treatment is not necessary if treatment results in lower blood pressure and treatment is well tolerated and without adverse effects on health or quality of life.</li> <li>• In patients <math>&lt; 60</math> years of age, pharmacologic treatment should be initiated to lower blood pressure at diastolic blood pressure <math>\geq 90</math> mm Hg to a goal diastolic blood pressure <math>&lt; 90</math> mm Hg.</li> <li>• In patients <math>&lt; 60</math> years of age, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure <math>\geq 150</math> mm Hg to a goal diastolic blood pressure <math>&lt; 140</math> mm Hg.</li> <li>• For patients <math>\geq 18</math> years of age with chronic kidney disease or diabetes, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure <math>\geq 140</math> mm Hg or diastolic blood pressure <math>\geq 90</math> mm Hg and to a goal systolic blood pressure <math>&lt; 140</math> mm Hg and goal diastolic blood pressure <math>&lt; 90</math> mm Hg.</li> <li>• Initial antihypertensive treatment for the general nonblack population, including those with diabetes, should include thiazide-type diuretic, calcium channel blocker (CCB), ACE inhibitor, or ARB.</li> <li>• Initial antihypertensive treatment for the general black population, including those with diabetes, should include thiazide-type diuretic or CCB.</li> <li>• For patients <math>\geq 18</math> years of age with chronic kidney disease regardless of race or diabetes status, initial (or add-on) treatment should include an ACE inhibitor or ARB to improve kidney outcomes.</li> <li>• The main goal of antihypertensive treatment is to attain and maintain goal blood pressure.</li> <li>• If goal blood pressure is not attained within a month of treatment, the dose of the initial drug should be increased or second drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• If goal is not achieved with two drugs, a third drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• An ACE inhibitor and ARB should not be used together.</li> <li>• Antihypertensive classes can be used if the patient is unable to achieve goal blood pressure with three agents or had a contraindication to a preferred class.</li> <li>• If blood pressure is not able to be achieved or in complicated patients, referral to a hypertension specialist may be indicated.</li> </ul>
<p>International Society of Hypertension: <b>Global Hypertension Practice Guidelines (2020)<sup>11</sup></b></p>	<p><u>Lifestyle modifications</u></p> <ul style="list-style-type: none"> <li>• Lifestyle modification is the first line of antihypertensive treatment.</li> <li>• Salt reduction: Reduce salt added when preparing foods, and at the table. Avoid or limit consumption of high salt foods such as soy sauce, fast foods and processed food including breads and cereals high in salt.</li> <li>• Healthy diet: Eating a diet that is rich in whole grains, fruits, vegetables, polyunsaturated fats and dairy products and reducing food high in sugar, saturated fat and trans fats, such as the DASH diet.</li> <li>• Healthy drinks: Moderate consumption of coffee, green and black tea. Other beverages that can be beneficial include karkadé (hibiscus) tea, pomegranate juice, beetroot juice and cocoa.</li> <li>• Moderation of alcohol consumption: The recommended daily limit for alcohol consumptions is 2 standard drinks for men and 1.5 for women (10 g</li> </ul>

Clinical Guideline	Recommendations
	<p>alcohol/standard drink). Avoid binge drinking.</p> <ul style="list-style-type: none"> <li>• Weight reduction: Body weight control is indicated to avoid obesity. Particularly abdominal obesity should be managed. Ethnic-specific cut-offs for BMI and waist circumference should be used. Alternatively, a waist-to-height ratio &lt;0.5 is recommended for all populations.</li> <li>• Smoking cessation: Smoking is a major risk factor for cardiovascular disease (CVD), COPD and cancer. Smoking cessation and referral to smoking cessation programs are advised.</li> <li>• Regular physical activity: Studies suggest that regular aerobic and resistance exercise may be beneficial for both the prevention and treatment of hypertension. Moderate intensity aerobic exercise (walking, jogging, cycling, yoga, or swimming) for 30 minutes on five to seven days per week. Strength training also can help reduce blood pressure. Performance of resistance/strength exercises on two to three days per week.</li> <li>• Reduce stress and induce mindfulness: Stress should be reduced and mindfulness or meditation introduced into the daily routine.</li> <li>• Reduce exposure to air pollution and cold temperature: Evidence from studies support a negative effect of air pollution on blood pressure in the long-term.</li> </ul> <p><b>Pharmacological Treatment</b></p> <ul style="list-style-type: none"> <li>• Ideal characteristics of drug treatment <ul style="list-style-type: none"> <li>○ Treatments should be evidence-based in relation to morbidity/mortality prevention.</li> <li>○ Use a once-daily regimen which provides 24-hour blood pressure control.</li> <li>○ Treatment should be affordable and/or cost-effective relative to other agents.</li> <li>○ Treatments should be well-tolerated.</li> <li>○ Evidence of benefits of use of the medication in populations to which it is to be applied.</li> </ul> </li> <li>• General scheme for drug treatment <ul style="list-style-type: none"> <li>○ Lifestyle modification is the first line of antihypertensive treatment.</li> <li>○ Grade 1 hypertension (BP 140 to 159/ 90 to 99): Immediate drug treatment in high-risk patients or those with CVD, chronic kidney disease (CKD), diabetes mellitus (DM), or hypertension-mediated organ damage (HMOD). Drug treatment after three to six months of lifestyle intervention if BP still not controlled in low to moderate risk patients.</li> <li>○ Grade 2 hypertension (BP <math>\geq</math>160/100): Immediate drug treatment in all patients.</li> </ul> </li> <li>• Core drug-treatment strategy <ul style="list-style-type: none"> <li>○ Step 1: Dual low-dose combination (ACE inhibitor or ARB plus dihydropyridine-calcium channel blockers (DHP-CCB)); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance; consider ACE/ARB plus DHP-CCB or DHP-CCB plus thiazide-like diuretics in black patients.</li> <li>○ Step 2: Dual full-dose combination (ACE inhibitor or ARB plus DHP-CCB); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance.</li> <li>○ Step 3: Triple combination (ACE/ARB plus DHP-CCB plus thiazide-like diuretic).</li> <li>○ Step 4, resistant hypertension: triple combination plus spironolactone or other drug, alternatives include amiloride, doxazosin, eplerenone, clonidine, or <math>\beta</math>-blocker. Caution with spironolactone or other potassium sparing diuretics when estimated GFR &lt;45 mL/min/1.73m<sup>2</sup> or K<sup>+</sup> &gt;4.5</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>mmol/L.</p> <ul style="list-style-type: none"> <li>○ Consider <math>\beta</math>-blockers at any treatment step when there is a specific indication for their use, e.g., heart failure, angina, post-MI, atrial fibrillation, or younger women planning pregnancy or pregnant.</li> </ul>
<p>Hypertension Canada: 2020 Guidelines for the Prevention, Diagnosis, Risk Assessment, and Treatment of Hypertension in Adults and Children (2020)<sup>12</sup></p>	<p><u>Indications for drug therapy for adults with hypertension without compelling indications for specific agents</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive therapy should be prescribed for average diastolic blood pressure (DBP) measurements of <math>\geq 100</math> mmHg or average systolic blood pressure (SBP) measurements of <math>\geq 160</math> mmHg in patients without macrovascular target organ damage or other cardiovascular risk factors.</li> <li>• Antihypertensive therapy should be strongly considered for average DPB readings <math>\geq 90</math> mmHg or for average SBP readings <math>\geq 140</math> mmHg in the presence of macrovascular target organ damage or other independent cardiovascular risk factors.</li> <li>• For high-risk patients, aged 50 years or older, with SBP levels <math>\geq 130</math> mmHg, intensive management to target a SBP <math>&lt; 120</math> mmHg should be considered. Patient selection for intensive management is recommended and caution should be taken in certain high-risk groups.</li> </ul> <p><u>Indications for drug therapy for adults with diastolic and with or without systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be with either monotherapy or single pill combination (SPC). <ul style="list-style-type: none"> <li>○ Recommended monotherapy choices are: <ul style="list-style-type: none"> <li>▪ A thiazide/thiazide-like diuretic, with longer-acting diuretics preferred;</li> <li>▪ A <math>\beta</math>-blocker (in patients <math>&lt; 60</math> years of age);</li> <li>▪ An angiotensin-converting enzyme (ACE) inhibitor (in nonblack patients);</li> <li>▪ An angiotensin receptor blocker (ARB); or</li> <li>▪ A long-acting calcium channel blocker (CCB).</li> </ul> </li> <li>○ Recommended SPC choices are those in which an ACE inhibitor is combined with a CCB, ARB with a CCB, or ACE inhibitor or ARB with a diuretic.</li> <li>○ Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> </ul> </li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line choices. Useful choices include a thiazide/thiazide-like diuretic or CCB with either: ACE inhibitor, ARB, or <math>\beta</math>-blocker. Caution should be exercised in combining a nondihydropyridine CCB and a <math>\beta</math>-blocker. The combination of an ACE inhibitor and an ARB is not recommended.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other antihypertensive drugs may be added.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated hypertension; <math>\beta</math>-blockers are not recommended as first-line therapy for uncomplicated hypertension in patients <math>\geq 60</math> years of age; and ACE inhibitors are not recommended as first-line therapy for uncomplicated hypertension in black patients. However, these agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Indications for drug therapy for adults with isolated systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be single-agent therapy with a thiazide/thiazide-like diuretic, a long-acting dihydropyridine CCB, or an ARB. If there are adverse effects, another drug from this group should be substituted. Hypokalemia should</li> </ul>

Clinical Guideline	Recommendations
	<p>be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</p> <ul style="list-style-type: none"> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line options.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other classes of drugs (such as <math>\alpha</math>-blockers, ACE inhibitors, centrally acting agents, or nondihydropyridine CCBs) may be combined or substituted.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated isolated systolic hypertension; and <math>\beta</math>-blockers are not recommended as first-line therapy for isolated systolic hypertension in patients <math>\geq 60</math> years of age. However, both agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Guidelines for hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• For most hypertensive patients with CAD, an ACE inhibitor or ARB is recommended.</li> <li>• For hypertensive patients with CAD, but without coexisting systolic heart failure, the combination of an ACE inhibitor and ARB is not recommended.</li> <li>• For high-risk hypertensive patients, when combination therapy is being used, choices should be individualized. The combination of an ACE inhibitor and a dihydropyridine CCB is preferable to an ACE inhibitor and a thiazide/thiazide-like diuretic in selected patients.</li> <li>• For patients with stable angina pectoris but without previous heart failure, myocardial infarction, or coronary artery bypass surgery, either a <math>\beta</math>-blocker or CCB can be used as initial therapy.</li> <li>• Short-acting nifedipine should not be used.</li> <li>• When decreasing SBP to target levels in patients with established CAD (especially if isolated systolic hypertension is present), be cautious when the DBP is <math>\leq 60</math> mmHg because of concerns that myocardial ischemia might be exacerbated, especially in patients with left ventricular hypertrophy (LVH).</li> </ul> <p><u>Guidelines for patients with hypertension who have had a recent myocardial infarction</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should include a <math>\beta</math>-blocker as well as an ACE inhibitor.</li> <li>• An ARB can be used if the patient is intolerant of an ACE inhibitor.</li> <li>• CCBs may be used in patients after myocardial infarction when <math>\beta</math>-blockers are contraindicated or not effective. Nondihydropyridine CCBs should not be used when there is heart failure, evidenced by pulmonary congestion on examination or radiography.</li> </ul> <p><u>Treatment of hypertension in association with heart failure</u></p> <ul style="list-style-type: none"> <li>• In patients with systolic dysfunction (ejection fraction <math>&lt; 40\%</math>), ACE inhibitors and <math>\beta</math>-blockers are recommended for initial therapy. Aldosterone antagonists (mineralocorticoid receptor antagonists) may be combined in treatment for patients with a recent cardiovascular hospitalization, acute myocardial infarction, elevated B-type natriuretic peptide or N-terminal pro-B-type natriuretic peptide level, or New York Heart Association (NYHA) Class II-IV symptoms. Careful monitoring for hyperkalemia is recommended when combining an aldosterone antagonist with ACE inhibitor or ARB treatment. Other diuretics are recommended as additional therapy if needed. Beyond considerations of BP control, doses of ACE inhibitors or ARBs should be titrated to those reported to be effective in trials unless adverse effects become manifest.</li> <li>• An ARB is recommended if ACE inhibitors are not tolerated.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• A combination of hydralazine and isosorbide dinitrate is recommended if ACE inhibitors and ARBs are contraindicated or not tolerated.</li> <li>• For hypertensive patients whose BP is not controlled, an ARB may be combined with an ACE inhibitor and other antihypertensive drug treatment. Careful monitoring should be used if combining an ACE inhibitor and an ARB because of potential adverse effects such as hypotension, hyperkalemia, and worsening renal function. Additional therapies may also include dihydropyridine CCBs.</li> <li>• An angiotensin receptor-neprilysin inhibitor (ARNI) should be used in place of an ACE inhibitor or ARB for patients with HFrEF (&lt;40%) who remain symptomatic despite treatment with appropriate dose of guideline directed HF therapy. Eligible patients must have a serum potassium &lt;5.2 mmol/L, an eGFR <math>\leq 30</math> mL/min/1.73m<sup>2</sup> and close surveillance of serum potassium and creatinine.</li> </ul> <p><u>Treatment of hypertension in association with stroke</u></p> <ul style="list-style-type: none"> <li>• BP management in acute ischemic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> <li>• BP management after acute ischemic stroke <ul style="list-style-type: none"> <li>○ Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack.</li> <li>○ After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently &lt;140/90 mmHg.</li> <li>○ Treatment with an ACE inhibitor and thiazide/thiazide-like diuretic combination is preferred.</li> <li>○ For patients with stroke, the combination of an ACE inhibitor and ARB is not recommended.</li> </ul> </li> <li>• BP management in hemorrhagic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> </ul> <p><u>Treatment of hypertension in association with LVH</u></p> <ul style="list-style-type: none"> <li>• Hypertensive patients with LVH should be treated with antihypertensive therapy to decrease the rate of subsequent cardiovascular events.</li> <li>• The choice of initial therapy can be influenced by the presence of LVH. Initial therapy can be drug treatment using ACE inhibitors, ARBs, long-acting CCBs, or thiazide/thiazide-like diuretics. Direct arterial vasodilators such as hydralazine or minoxidil should not be used.</li> </ul> <p><u>Treatment of hypertension in association with nondiabetic chronic kidney disease</u></p> <ul style="list-style-type: none"> <li>• Individualize BP targets in patients with chronic kidney disease. Consider intensive targets (SBP &lt;120 mmHg) in appropriate patients.</li> <li>• For patients with hypertension and proteinuric chronic kidney disease (urinary protein &gt;150 mg per 24 hours or albumin to creatinine ratio &gt;30 mg/mmol), initial therapy should be an ACE inhibitor or an ARB if there is intolerance to ACE inhibitors.</li> <li>• In most cases, combination therapy with other antihypertensive agents might be needed to reach target BP levels.</li> <li>• The combination of an ACE inhibitor and ARB is not recommended for patients with nonproteinuric chronic kidney disease.</li> </ul> <p><u>Treatment of hypertension in association with renovascular disease</u></p> <ul style="list-style-type: none"> <li>• Patients with hypertension attributable to atherosclerotic renal artery stenosis should be primarily medically managed because renal angioplasty and stenting offers no benefit over optimal medical therapy alone.</li> <li>• Renal artery angioplasty and stenting for atherosclerotic hemodynamically significant renal artery stenosis could be considered for patients with uncontrolled hypertension resistant to maximally tolerated pharmacotherapy, progressive renal</li> </ul>

Clinical Guideline	Recommendations
	<p>function loss, and acute pulmonary edema.</p> <ul style="list-style-type: none"> <li>• Patients with confirmed renal fibromuscular dysplasia (FMD) should be referred to a hypertension specialist.</li> <li>• Renal artery angioplasty without stenting is recommended for treatment of FMD-related renal artery stenosis. Stenting is not recommended unless needed because of a periprocedural dissection. Surgical revascularization should be considered in cases of complex lesions less amendable to angioplasty, stenosis associated with complex aneurysm, and restenosis despite two unsuccessful attempts of angioplasty.</li> </ul> <p><u>Treatment of hypertension in association with diabetes mellitus</u></p> <ul style="list-style-type: none"> <li>• Persons with diabetes mellitus should be treated to attain SBP of &lt;130 mmHg and DBP of &lt;80 mmHg.</li> <li>• For persons with cardiovascular or kidney disease, including microalbuminuria, or with cardiovascular risk factors in addition to diabetes and hypertension, an ACE inhibitor or an ARB is recommended as initial therapy.</li> <li>• For persons with diabetes and hypertension not included in other guidelines in this section, appropriate choices include (in alphabetical order): ACE inhibitors, ARBs, dihydropyridine CCBs, and thiazide/thiazide-like diuretics.</li> <li>• If target BP levels are not achieved with standard-dose monotherapy, additional antihypertensive therapy should be used. For persons in whom combination therapy with an ACE inhibitor is being considered, a dihydropyridine CCB is preferable to a thiazide/thiazide-like diuretic.</li> </ul> <p><u>Resistant hypertension</u></p> <ul style="list-style-type: none"> <li>• Resistant hypertension is defined as BP above target despite three or more BP-lowering drugs at optimal doses preferably including a diuretic (and usually a renin-angiotensin-aldosterone system blocker and a CCB).</li> <li>• Accurate office and out-of-office BP measurement is essential.</li> <li>• Other reasons for apparent resistant hypertension should be eliminated before diagnosing true resistant hypertension, including nonadherence, white coat effect, and secondary hypertension.</li> <li>• Pharmacotherapy with the additional use of spironolactone, bisoprolol, doxazosin, amiloride, eplerenone, or clonidine with the baseline regimen decreases BP significantly, with the greatest BP-lowering shown with spironolactone.</li> <li>• Patients with resistant hypertension should be referred to providers with expertise in diagnosis and management of hypertension.</li> </ul> <p><u>Hypertension and pediatrics</u></p> <ul style="list-style-type: none"> <li>• BP should be measured regularly in children three years of age or older; the auscultatory method is the gold-standard at present.</li> <li>• Initial therapy should be monotherapy, with an ACE inhibitor or ARB (not first-line in black children), or a long-acting dihydropyridine CCB.</li> <li>• The treatment goal is systolic and diastolic office BP and/or ABPM &lt; 95th percentile or &lt;90<sup>th</sup> percentile in children with risk factors or target organ damage.</li> <li>• Complex cases should be referred to an expert in pediatric hypertension.</li> </ul> <p><u>Hypertension and pregnancy</u></p> <ul style="list-style-type: none"> <li>• Up to 7% of pregnancies are complicated by a hypertensive disorder of pregnancy, and approximately 5% of women will have chronic hypertension when they become pregnant.</li> <li>• The prevalence of hypertension in pregnancy is expected to increase with women becoming pregnant later in their reproductive years and the increasing prevalence of cardiovascular comorbidities such as increased preconception body mass index</li> </ul>

Clinical Guideline	Recommendations
	<p>and maternal diabetes.</p> <ul style="list-style-type: none"> <li>• The possibility of pregnancy should be considered when managing women with hypertension who are of reproductive age.</li> <li>• Preconception counselling should be offered to all women with hypertension who are considering pregnancy.</li> <li>• ACE inhibitor and ARB therapy should be avoided before conception and during pregnancy unless there is a compelling indication for their use (i.e., proteinuric kidney disease).</li> <li>• Hypertension during pregnancy can increase the risk of adverse maternal and fetal outcomes, including an increased risk of preeclampsia, placental abruption, prematurity, small for gestational age infants, stillbirth, and maternal renal and retinal injury, thus generally requires involvement of an interdisciplinary team including obstetrical care providers.</li> <li>• Antihypertensive therapy is recommended for average SBP measurements of <math>\geq 140</math> mmHg or DBP measurements of <math>\geq 90</math> mmHg in pregnant women with chronic hypertension, gestational hypertension, or preeclampsia. Initial antihypertensive therapy should be monotherapy from the following first-line drugs: oral labetalol, oral methyldopa, long-acting oral nifedipine, or other oral <math>\beta</math>-blockers (acebutolol, metoprolol, pindolol, and propranolol). Other antihypertensive drugs can be considered as second-line drugs including: clonidine, hydralazine, and thiazide diuretics.</li> <li>• Women with severe hypertension with SBP <math>\geq 160</math> mmHg or DBP <math>\geq 110</math> mmHg in pregnancy or postpartum require urgent antihypertensive therapy because it is considered an obstetrical emergency.</li> <li>• Antihypertensive drugs used in breastfeeding women include: labetalol, methyldopa, long-acting nifedipine, enalapril, or captopril.</li> </ul>
<p>European Society of Hypertension/ European Society of Cardiology: <b>2018 Guidelines for the management of arterial hypertension (2018)</b><sup>13</sup></p>	<p><u>Treatment strategies and choice of antihypertensive drugs</u></p> <ul style="list-style-type: none"> <li>• Diuretics (including thiazides, chlorthalidone, and indapamide), <math>\beta</math>-blockers, calcium channel blocker (CCB), angiotensin-converting enzyme (ACE) inhibitors, and angiotensin receptor blockers (ARBs) are all suitable for the initiation and maintenance of antihypertensive treatment, either as monotherapy or in some combinations.</li> <li>• Some agents should be considered as the preferential choice in specific conditions because used in trials in those conditions or because of greater effectiveness in specific types of organ damage. Preferred combinations should comprise a renin-angiotensin system (RAS) blocker (either an ACE inhibitor or an ARB) with a CCB or diuretic.</li> <li>• It is recommended that beta-blockers are combined with any of the other major drug classes when there are specific clinical situations, e.g. angina, post-myocardial infarction, heart failure, or heart rate control.</li> <li>• Initiation of antihypertensive therapy with a two-drug combination may be considered in patients with markedly high baseline blood pressure (BP) or at high cardiovascular (CV) risk.</li> <li>• The combination of two antagonists of the RAS is not recommended and should be discouraged.</li> <li>• Other drug combinations should be considered and probably are beneficial in proportion to the extent of BP reduction. However, combinations that have been successfully used in trials may be preferable.</li> <li>• Combinations of two antihypertensive drugs at fixed doses in a single tablet may be recommended and favored, because reducing the number of daily pills improves adherence, which is low in patients with hypertension. Exceptions are frail older patients and those at low risk and with grade one hypertension (particularly if systolic BP is <math>&lt; 150</math> mmHg).</li> <li>• It is recommended that if BP is not controlled with a three-drug combination, treatment should be increased by the addition of spironolactone or, if not</li> </ul>

Clinical Guideline	Recommendations
	<p>tolerated, other diuretics such as amiloride or higher doses of other diuretics, a beta-blocker, or an alpha-blocker.</p> <p><u>Treatment strategies in white-coat and masked hypertension</u></p> <ul style="list-style-type: none"> <li>• In white-coat hypertensives without additional risk factors, therapeutic intervention may be limited to lifestyle changes only, but this decision should be accompanied by close follow-up.</li> <li>• In white-coat hypertensives with a higher CV risk or hypertension-mediated organ damage, drug treatment may be considered in addition to lifestyle changes.</li> <li>• In masked hypertension, both lifestyle measures and antihypertensive drug treatment should be considered, because this type of hypertension has been consistently found to have a CV risk very close to that of in- and out-of-office hypertension.</li> <li>• Antihypertensive drug up-titration should be considered in treated patients whose out-of-office BP is not controlled (i.e., masked uncontrolled hypertension), because of the high CV risk of these patients.</li> </ul> <p><u>Antihypertensive treatment strategies in the elderly</u></p> <ul style="list-style-type: none"> <li>• It is recommended that older patients (<math>\geq 65</math> years) are treated with the same recommendations in non-older patient population. In very old patients (<math>\geq 80</math> years), it may be appropriate to initiate treatment with monotherapy.</li> <li>• In all older patients, when combination therapy is used, it is recommended that this is initiated at the lowest available doses. In all older patients, and especially very old or frail patients, the possible occurrence of postural BP should be closely monitored and symptoms of possible hypotensive episodes checked by ambulatory blood pressure monitoring.</li> <li>• Unless required for concomitant diseases, loop diuretics and alpha-blockers should be avoided because of their association with injurious falls.</li> <li>• Renal function should be frequently assessed to detect possible increases in serum creatinine and reductions in estimated glomerular filtration rate (eGFR) as a result of BP-related reductions in renal perfusion.</li> <li>• When treated, BP should be lowered to a systolic value of 130 to 139 mmHg and a diastolic value of <math>&lt; 80</math> mmHg if tolerated. Treated values of <math>&lt; 130</math> mmHg should be avoided.</li> </ul> <p><u>Treatment strategies in hypertensive women</u></p> <ul style="list-style-type: none"> <li>• Hormone therapy and selective estrogen receptor modulators are not recommended and should not be used for primary or secondary prevention of CVD.</li> <li>• In women with gestational hypertension, pre-existing hypertension superimposed by gestational hypertension, or with hypertension and subclinical organ damage or symptoms, initiation of drug treatments is recommended when SBP is <math>\geq 140</math> mmHg or DBP <math>\geq 90</math> mmHg. In all other cases, initiation of drug treatment is recommended when SBP is <math>\geq 150</math> mmHg or DBP is <math>\geq 95</math> mmHg.</li> <li>• Methyldopa, labetalol, and CCBs are recommended as the drugs of choice for the treatment of hypertension in pregnancy.</li> <li>• ACE inhibitors, ARBs, or direct renin inhibitors are not recommended during pregnancy.</li> <li>• SBP <math>\geq 170</math> mmHg or DBP <math>\geq 110</math> mmHg in a pregnant woman is an emergency, and admission to hospital is recommended.</li> <li>• In severe hypertension, drug treatment with intravenous (IV) labetalol, oral methyldopa, or nifedipine is recommended.</li> <li>• The recommended treatment for hypertensive crisis is IV labetalol or nicardipine and magnesium.</li> <li>• In pre-eclampsia associated with pulmonary edema, nitroglycerin given as an IV</li> </ul>

Clinical Guideline	Recommendations
	<p>infusion is recommended.</p> <ul style="list-style-type: none"> <li>• In women with gestational hypertension or mild-pre-eclampsia, delivery is recommended at 37 weeks.</li> <li>• It is recommended to expedite delivery in pre-eclampsia with adverse conditions, such as visual disturbances or hemostatic disorders</li> <li>• In women at high risk of pre-eclampsia, provided they are at low risk of gastrointestinal hemorrhage, treatment with low dose aspirin from 12 weeks until delivery may be considered.</li> <li>• Methyldopa, labetalol, and nifedipine should be considered preferential antihypertensive drugs in pregnancy. Intravenous labetalol or infusion of nitroprusside should be considered in case of emergency (pre-eclampsia).</li> </ul> <p><u>Treatment strategies in patients with diabetes</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive drug treatment is recommended for people with diabetes when office BP is <math>\geq 140/90</math> mmHg.</li> <li>• A SBP goal <math>&lt; 130</math> mmHg is recommended in patients with diabetes and <math>&lt; 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg.</li> <li>• In older people, the target SBP range is 130 to 139 mmHg.</li> <li>• The DBP target in patients with diabetes is recommended to be <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• It is recommended to initiate treatment with a combination of a RAS blocker with a CCB or thiazide/thiazide-like diuretic.</li> <li>• It is recommended that individual drug choice takes comorbidities into account.</li> <li>• Simultaneous administration of two blockers of the RAS is not recommended and should be avoided in patients with diabetes.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with nephropathy</u></p> <ul style="list-style-type: none"> <li>• In patients with diabetic and non-diabetic CKD, it is recommended that an office BP of <math>\geq 140/90</math> mmHg be treated with lifestyle advice and BP-lowering medication.</li> <li>• In patients with diabetic or non-diabetic CKD, it is recommended to lower SBP to a range of 130 to 139 mmHg. And individualized treatments should be considered according to its tolerability and impact on renal function and electrolytes.</li> <li>• A combination of a RAS blocker with a CCB or a diuretic is recommended as initial therapy.</li> <li>• RAS blockers are more effective in reducing albuminuria than other antihypertensive agents, and are indicated in hypertensive patients in the presence of microalbuminuria or overt proteinuria.</li> <li>• Combination of two RAS blockers, though potentially more effective in reducing proteinuria, is not recommended.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with cerebrovascular disease</u></p> <ul style="list-style-type: none"> <li>• In patients with acute intracerebral hemorrhage, immediate BP lowering is not recommended for patients with SBP <math>&lt; 220</math> mmHg. In patients with SBP <math>\geq 220</math> mmHg, care acute BP lowering with IV therapy to <math>&lt; 180</math> mmHg should be considered.</li> <li>• In acute ischemic stroke, routine BP lowering with antihypertensive therapy is not recommended with the exceptions with the exceptions: in patients with acute ischemic stroke who are eligible for IV thrombolysis, BP should be carefully lowered and maintained at <math>&lt; 180/105</math> mmHg for at least the first 24 hours after thrombolysis; In patients with markedly elevated BP who do not receive fibrinolysis, drug therapy may be considered, based on clinical judgement, to reduce BP by 15% during the first 24 hours after the stroke onset.</li> <li>• In hypertensive patients with an acute cerebrovascular event, antihypertensive</li> </ul>

Clinical Guideline	Recommendations
	<p>treatment is recommended immediately for transient ischemic attack (TIA) and after several days in ischemic stroke.</p> <ul style="list-style-type: none"> <li>• In all hypertensive patients with ischemic stroke or TIA, an SBP target range of 120 to 130 mmHg should be considered.</li> <li>• The recommended antihypertensive drug treatment strategy for stroke prevention is a RAS blocker plus a CCB or a thiazide-like diuretic.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with heart failure (HF) or left ventricular hypertrophy (LVH)</u></p> <ul style="list-style-type: none"> <li>• In hypertensive patients with heart failure (with reduced or preserved ejection fraction), BP-lowering treatment should be considered if <math>\geq 140/90</math> mmHg.</li> <li>• In patients with HFrEF, it is recommended that BP-lowering treatment comprises an ACE inhibitor or ARB, and a beta-blocker and a diuretic and/or mineralocorticoid receptor antagonist (MRA) if required.</li> <li>• Dihydropyridine CCBs may be added if BP control is not achieved.</li> <li>• In patients with HFpEF, BP treatment threshold and target values should be the same as for HFrEF).</li> <li>• Because no specific drug has proven its superiority, all major agents can be used.</li> <li>• In all patients with LVH, it is recommended to treat with a RAS blocker or in combination with a CCB or diuretic and SBP should be lowered to a range of 120 to 130 mmHg.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• In patients with CAD receiving BP-lowering drugs, it is recommended to target SBP to <math>\leq 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg. In older patients, the target is an SBP range of 130 to 140 mmHg. The target DBP is <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• In hypertensive patients with a history of myocardial infarction, beta-blockers and RAS blockers are recommended as part of treatment.</li> <li>• In patients with asymptomatic angina, beta-blockers and/or CCBs are recommended.</li> </ul>
<p>National Institute for Health and Clinical Excellence: <b>Hypertension in adults: diagnosis and management (2019)</b><sup>14</sup></p>	<p><u>Choosing antihypertensive drug treatment (for people with or without type II diabetes)</u></p> <ul style="list-style-type: none"> <li>• Where possible, recommend treatment with drugs taken only once a day.</li> <li>• Prescribe non-proprietary drugs where these are appropriate and minimize cost.</li> <li>• Offer people with isolated systolic hypertension (systolic blood pressure <math>\geq 160</math> mmHg) the same treatment as people with both raised systolic and diastolic blood pressure.</li> <li>• Offer antihypertensive drug treatment to women of child-bearing potential with diagnosed hypertension in line with recommendations in this guideline. For women considering pregnancy or who are pregnant or breastfeeding, manage hypertension in line with the recommendations on Management of pregnancy with chronic hypertension and Breastfeeding in 'Hypertension in pregnancy'.</li> <li>• When choosing antihypertensive drug treatment for adults of black African or African-Caribbean family origin, consider an angiotensin II receptor blocker, in preference to an angiotensin-converting enzyme inhibitor.</li> </ul> <p><u>Step one treatment</u></p> <ul style="list-style-type: none"> <li>• Patients <math>&lt; 55</math> years of age should be offered a step one antihypertensive with an angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB).</li> <li>• Offer an ACE inhibitor or an ARB to adults starting step 1 antihypertensive treatment who have type II diabetes and are of any age or family origin or those aged <math>&lt; 55</math> years but not of black African or African-Caribbean family origin.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• If an ACE inhibitor is not tolerated, offer an ARB.</li> <li>• Do not combine an ACE inhibitor with an ARB for the treatment of hypertension.</li> <li>• Offer a calcium channel blocker (CCB) to adults starting step 1 antihypertensive treatment who are &gt;55 years of age and do not have diabetes and are of black African or African-Caribbean family origin and do not have type II diabetes and of any age.</li> <li>• If a CCB is not suitable, for example because of edema or intolerance, or if there is evidence of heart failure or a high risk of heart failure, offer a thiazide-like diuretic.</li> <li>• If diuretic treatment is to be initiated or changed, offer a thiazide-like diuretic, such as indapamide in preference to a conventional thiazide diuretic such as bendroflumethiazide or hydrochlorothiazide.</li> <li>• For adults with hypertension who are already receiving treatment with bendroflumethiazide or hydrochlorothiazide, who have stable, well-controlled blood pressure, continue with their treatment.</li> </ul> <p><u>Step two treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering next step treatment for hypertension discuss with the person if they are taking their medicine as prescribed and support adherence in line with NICE's guideline on "Medicines adherence: involving patients decisions about prescribed medicines and supporting adherence".</li> <li>• If hypertension is not controlled with a step one treatment of an ACE inhibitor or ARB, offer choice of one of the following drugs in addition to the step one treatment: a CCB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults taking step one treatment of a CCB, offer the choice of one of the following drugs in addition to the step one treatment: an ACE inhibitor or an ARB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults of black African or African-Caribbean family origin who do not have type 2 diabetes taking step one treatment, consider an ARB, in preference to an ACE inhibitor, in addition to step one treatment.</li> </ul> <p><u>Step three treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering step three treatment, review the person's medications to ensure they are being taken at the optimal doses and discuss adherence (see recommendation under step two).</li> <li>• If hypertension is not controlled in adults taking step two treatment, offer a combination of an ACE inhibitor or ARB and a CCB and a thiazide-like diuretic.</li> </ul> <p><u>Step four treatment</u></p> <ul style="list-style-type: none"> <li>• If hypertension is not controlled in adults taking the optimal tolerated doses of an ACE inhibitor or an ARB plus a CCB and a thiazide-like diuretic, regard them as having resistant hypertension.</li> <li>• Before considering further treatment for a person with resistant hypertension, confirm elevated clinic blood pressure measurements using ambulatory or home blood pressure recordings, assess for postural hypotension, and discuss adherence.</li> <li>• For people with confirmed resistant hypertension, consider adding a fourth antihypertensive drug as step four treatment or seeking specialist advice.</li> <li>• Consider further diuretic therapy with low-dose spironolactone for adults with resistant hypertension starting step four treatment who have a blood potassium level of 4.5 mmol/l or less. Use particular caution in people with a reduced estimated glomerular filtration rate because they have an increased risk of hyperkalemia.</li> <li>• When using further diuretic therapy for step four treatment of resistant</li> </ul>

Clinical Guideline	Recommendations
	<p>hypertension, monitor blood sodium and potassium and renal function within one month of starting treatment and repeat as needed thereafter.</p> <ul style="list-style-type: none"> <li>• Consider an alpha-blocker or beta-blocker for adults with resistant hypertension starting step four treatment who have a blood potassium level of more than 4.5 mmol/l.</li> <li>• If blood pressure remains uncontrolled in people with resistant hypertension taking the optimal tolerated doses of four drugs, seek specialist advice.</li> </ul>
<p>International Society on Hypertension in Blacks: <b>Management of High Blood Pressure in Blacks (2010)</b><sup>15</sup></p>	<ul style="list-style-type: none"> <li>• To attain and maintain blood pressure (BP) below target levels, multiple antihypertensive drugs will be required in most hypertensive blacks.</li> <li>• Use of two-drug combination therapy when SBP is &gt;15 mm Hg and/or DBP is &gt;10 mm Hg above goal levels is increasingly recommended as first-line therapy.</li> <li>• Two-drug regimens have generally contained a thiazide-type diuretic; however, the combination of a calcium channel blocker (CCB) with either an ACE inhibitor or an ARB has been shown equally efficacious in BP lowering but with demonstrated superiority (CCB+ACE) for hard clinical outcomes compared with the same ACE inhibitor plus a thiazide-type diuretic.</li> <li>• In secondary prevention patients, the combination therapy should include a drug(s) with the appropriate compelling indications.</li> <li>• Certain classes of antihypertensive medications, specifically diuretics and CCBs, lower BP on average more than <math>\beta</math>-blockers and renin-angiotensin system (RAS) blockers in black patients when used as monotherapies.</li> <li>• In the absence of compelling indications, when BP is near goal levels, monotherapy with a diuretic or a CCB is preferred.</li> <li>• Lifestyle modifications should be initiated in all patients with hypertension, whether or not pharmacotherapy is planned.</li> <li>• ACE inhibitors or ARBs are recommended as alternative monotherapy options in the treatment of hypertension in blacks. The rationale for their lower tier monotherapy recommendation is because they have consistently achieved lesser average reductions in BP relative to that observed with monotherapy using either a diuretic or CCB.</li> </ul>
<p>Kidney Disease Improving Clinical Outcomes Group; <b>KDIGO Clinical Practice Guideline for the Management of Blood Pressure in Chronic Kidney Disease (2021)</b><sup>16</sup></p>	<p><u>Blood pressure measurement</u></p> <ul style="list-style-type: none"> <li>• The Work Group recommends standardized office blood pressure (BP) measurement in preference to routine office BP measurements for the management of high BP in adults.</li> <li>• The Work Group suggests that out-of-office BP measurements with ambulatory BP monitoring (ABPM) or home BP monitoring (HBPM) be used to complement standardized office BP readings for the management of high BP.</li> </ul> <p><u>Lifestyle interventions for lowering BP in patients with chronic kidney disease (CKD) not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>• The Work Group suggests targeting a sodium intake &lt;2 grams of sodium per day (or &lt;90 mmol of sodium per day, or &lt;5 grams of sodium chloride per day) in patients with high BP and CKD.</li> <li>• The Work Group suggests that patients with high BP and CKD be advised to undertake moderate-intensity physical activity for a cumulative duration of at least 150 minutes per week, or to a level compatible with their cardiovascular and physical tolerance.</li> </ul> <p><u>BP management in patients with CKD, with or without diabetes, not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>• The Work Group suggests that adults with high BP and CKD be treated with a target systolic BP (SBP) of &lt;120 mmHg, when tolerated, using standardized office BP measurement.</li> <li>• The Work Group recommends starting renin-angiotensin-system inhibitors</li> </ul>

Clinical Guideline	Recommendations
	<p>(RASi) (angiotensin-converting enzyme inhibitor [ACEi] or angiotensin II receptor blocker [ARB]) for people with high BP, CKD, and severely increased albuminuria without diabetes.</p> <ul style="list-style-type: none"> <li>• The Work Group suggests starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately increased albuminuria without diabetes.</li> <li>• The Work Group recommends starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately-to-severely increased albuminuria with diabetes.</li> <li>• The Work Group recommends avoiding any combination of ACEi, ARB, and direct renin inhibitor (DRI) therapy in patients with CKD, with or without diabetes.</li> </ul> <p><b>BP management in kidney transplant recipients</b></p> <ul style="list-style-type: none"> <li>• Treat adult kidney transplant recipients with high BP to a target BP of &lt;130 mmHg systolic and &lt;80 mmHg diastolic using standardized office BP measurement.</li> <li>• The Work Group recommends that a dihydropyridine calcium channel blocker (CCB) or an ARB be used as the first-line antihypertensive agent in adult kidney transplant recipients.</li> </ul> <p><b>BP management in children with CKD</b></p> <ul style="list-style-type: none"> <li>• The Work Group suggests that in children with CKD, 24-hour mean arterial pressure by ABPM should be lowered to &lt;50<sup>th</sup> percentile for age, sex, and height.</li> </ul>
<p>American Diabetes Association: <b>Standards of Medical Care in Diabetes (2022)</b><sup>17</sup></p>	<p><b>Hypertension/blood pressure control</b></p> <ul style="list-style-type: none"> <li>• Blood pressure should be measured at every routine visit. When possible, patients found to have elevated blood pressure (<math>\geq 140/90</math>) should have blood pressure confirmed using multiple readings, including measurements on a separate day, to diagnose hypertension. Patients with blood pressure <math>\geq 180/110</math> and cardiovascular disease could be diagnosed with hypertension at a single visit.</li> <li>• All hypertensive patients with diabetes should monitor their blood pressure at home.</li> <li>• For patients with diabetes and hypertension, with diabetes and hypertension, blood pressure targets should be individualized through a shared decision-making process that addresses cardiovascular risk, potential adverse effects of antihypertensive medications, and patient preferences.</li> <li>• For individuals with diabetes and hypertension at higher cardiovascular risk (existing atherosclerotic cardiovascular disease [ASCVD] or 10-year ASCVD risk <math>\geq 15\%</math>), a blood pressure target of &lt;130/80 mmHg may be appropriate, if it can be safely attained.</li> <li>• For individuals with diabetes and hypertension at lower risk for cardiovascular disease (10-year atherosclerotic cardiovascular disease risk &lt;15%), treat to blood pressure target of &lt;140/90.</li> <li>• In pregnant patients with diabetes and preexisting hypertension, a blood pressure target of 110 to 135/85 is suggested in the interest of reducing the risk for accelerated maternal hypertension and minimizing impaired fetal growth.</li> <li>• For patients with blood pressure &gt;120/80, lifestyle intervention consists of weight loss when indicated, a Dietary Approaches to Stop Hypertension (DASH)-style eating pattern including reducing sodium and increasing potassium intake, moderation of alcohol intake, and increased physical activity.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq 140/90</math> mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of pharmacologic therapy to achieve blood pressure goals.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq 160/100</math> mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of two drugs or a single pill combination of drugs demonstrated to reduce cardiovascular events in patients with diabetes.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Treatment for hypertension should include drug classes demonstrated to reduce cardiovascular events in patients with diabetes (ACE inhibitors, angiotensin receptor blockers, thiazide-like diuretics, or dihydropyridine calcium channel blockers). ACE inhibitors or angiotensin receptor blockers are recommended first-line therapy for hypertension in people with diabetes and coronary artery disease.</li> <li>• Multiple-drug therapy is generally required to achieve blood pressure targets (but not a combination of ACE inhibitors and angiotensin receptor blockers).</li> <li>• An ACE inhibitor or angiotensin receptor blocker, at the maximum tolerated dose indicated for blood pressure treatment, is the recommended first-line treatment for hypertension in patients with diabetes and urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine or 30 to 299 mg/g creatinine. If one class is not tolerated, the other should be substituted.</li> <li>• For patients treated with an ACE inhibitor, angiotensin receptor blocker, or diuretic, serum creatinine/estimated glomerular filtration rate and serum potassium levels should be monitored at least annually.</li> <li>• Patients with hypertension who are not meeting blood pressure targets on three classes of antihypertensive medications (including a diuretic) should be considered for mineralocorticoid receptor antagonist therapy.</li> </ul> <p><b>Chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>• At least once a year, assess urinary albumin (e.g., spot urinary albumin-to-creatinine ratio) and estimated glomerular filtration rate in patients with type 1 diabetes with duration of five or more years and in all patients with type 2 diabetes.</li> <li>• Patients with diabetes and urinary albumin <math>\geq 300</math> mg/g creatinine and/ or an estimated glomerular filtration rate 30 to 60 mL/min/1.73 m<sup>2</sup> should be monitored twice annually to guide therapy.</li> <li>• Optimize glucose control to reduce the risk or slow the progression of chronic kidney disease (CKD).</li> <li>• For patients with type 2 diabetes and diabetic kidney disease, use of a sodium-glucose cotransporter 2 inhibitor in patients with an estimated glomerular filtration rate <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> and urinary albumin <math>\geq 300</math> mg/g creatinine is recommended to reduce CKD progression and cardiovascular events..</li> <li>• In patients with type 2 diabetes and CKD, consider use of sodium-glucose cotransporter 2 inhibitors additionally for cardiovascular risk reduction when estimated glomerular filtration rate and urinary albumin creatinine are <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> or <math>\geq 300</math> mg/g, respectively.</li> <li>• In patients with CKD who are at increased risk for cardiovascular events or CKD progression and are unable to use a sodium-glucose cotransporter 2 inhibitor, a nonsteroidal mineralocorticoid receptor antagonist (finerenone) is recommended to reduce CKD progression and cardiovascular events.</li> <li>• Optimize blood pressure control and reduce blood pressure variability to reduce the risk or slow the progression of CKD.</li> <li>• Do not discontinue renin-angiotensin system blockade for minor increases in serum creatinine (<math>\leq 30\%</math>) in the absence of volume depletion.</li> <li>• For people with nondialysis-dependent stage 3 or higher CKD, dietary protein intake should be a maximum of 0.8 g/kg body weight per day (the recommended daily allowance). For patients on dialysis, higher levels of dietary protein intake should be considered, since malnutrition is a major problem in some dialysis patients.</li> <li>• In nonpregnant patients with diabetes and hypertension, either an ACE inhibitor or an angiotensin receptor blocker is recommended for those with modestly elevated urinary albumin-to-creatinine ratio (30 to 299 mg/g creatinine) and is strongly recommended for those with urinary albumin-to-creatinine ratio <math>\geq 300</math></li> </ul>

Clinical Guideline	Recommendations
	<p>mg/g creatinine and/or estimated glomerular filtration rate &lt;60 mL/min/1.73 m<sup>2</sup>.</p> <ul style="list-style-type: none"> <li>Periodically monitor serum creatinine and potassium levels for the development of increased creatinine or changes in potassium when ACE inhibitors, angiotensin receptor blockers, or diuretics are used.</li> <li>An ACE inhibitor or an angiotensin receptor blocker is not recommended for the primary prevention of CKD in patients with diabetes who have normal blood pressure, normal urinary albumin-to-creatinine ratio (&lt;30 mg/g creatinine), and normal estimated glomerular filtration rate.</li> <li>Patients should be referred for evaluation by a nephrologist if they have an estimated glomerular filtration rate &lt;30 mL/min/1.73 m<sup>2</sup>.</li> <li>Promptly refer to a nephrologist for uncertainty about the etiology of kidney disease, difficult management issues, and rapidly progressing kidney disease.</li> </ul>
<p>American College of Cardiology/American Heart Association Task Force: <b>Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults (2017)</b><sup>18</sup></p>	<p><u>Initiation of Blood Pressure (BP) Treatment for Overall Cardiovascular Disease (CVD) Risk</u></p> <ul style="list-style-type: none"> <li>Use of BP-lowering medications is recommended for secondary prevention of recurrent CVD events in patients with clinical CVD and an average systolic blood pressure (SBP) ≥130 mmHg or an average diastolic blood pressure (DBP) of ≥80 mmHg and for primary prevention in adults with an estimated 10-year atherosclerotic cardiovascular disease (ASCVD) risk of ≥10% and an average SBP of ≥130 mmHg or an average DBP of ≥80 mmHg.</li> <li>Use of BP-lowering medication is recommended for primary prevention of CVD in adults with no history of CVD and with an estimated 10-year ASCVD risk &lt;10% and an SBP of ≥140 mmHg or a DBP of ≥90 mmHg.</li> <li>Simultaneous use of an angiotensin converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), and/or renin inhibitor is potentially harmful and is not recommended to treat adults with hypertension.</li> <li>For adults with confirmed hypertension and known CVD or 10-year ASCVD risk of ≥10%, a BP target &lt;130/80 mmHg is recommended. For adults with confirmed hypertension without additional markers of increased CVD risk, a BP target &lt;130/80 mmHg may be reasonable.</li> <li>For initiation of antihypertensive drug therapy, first-line agents include thiazide diuretics, calcium channel blockers (CCBs), and ACE inhibitors or ARBs.</li> <li>Initiation of antihypertensive drug therapy with two first-line agents of different classes, either as separate agents or in a fixed-dose combination, is recommended in adults with stage 2 hypertension and an average BP &gt;20/10 mmHg above their BP target.</li> <li>Initiation of antihypertensive drug therapy with a single antihypertensive drug is reasonable in adults with stage 1 hypertension and BP goal &lt;130/80 mmHg with dosage titration and sequential addition of other agents to achieve the BP target.</li> </ul> <p><u>Stable Ischemic Heart Disease (SIHD)</u></p> <ul style="list-style-type: none"> <li>In adults with SIHD and hypertension, a BP target &lt;130/80 is recommended.</li> <li>Adults with SIHD and hypertension (BP ≥130/80 mmHg) should be treated with medications [e.g., guideline-directed medical therapy (GDMT) beta-blockers, ACE inhibitors, or ARBs] for compelling indications [e.g., previous myocardial infarction (MI), stable angina] as first-line therapy, with the addition of other drugs (e.g., dihydropyridine CCBs, thiazide diuretics, and/or mineralocorticoid receptor antagonists) as needed to further control hypertension.</li> <li>In adults with SIHD with angina and persistent uncontrolled hypertension, the addition of dihydropyridine CCBs to GDMT beta-blockers is recommended.</li> <li>In adults who have had a MI or acute coronary syndrome, it is reasonable to continue GDMT beta-blockers beyond three years as long-term therapy for hypertension.</li> <li>Beta-blockers and/or CCBs might be considered to control hypertension in patients with coronary artery disease (CAD) had an MI more than three years ago</li> </ul>

Clinical Guideline	Recommendations
	<p>and have angina.</p> <p><u>Heart Failure</u></p> <ul style="list-style-type: none"> <li>• In adults with increased risk of HF, the optimal BP in those with hypertension should be &lt;130 mmHg.</li> <li>• Adults with HFrEF and hypertension should be prescribed GDMT titrated to attain a BP &lt;130/80 mmHg.</li> <li>• Non-dihydropyridine CCBs are not recommended in the treatment of hypertension in adults with HFrEF.</li> <li>• In adults with HFpEF who present with symptoms of volume overload, diuretics should be prescribed to control hypertension.</li> <li>• Adults with HFpEF and persistent hypertension after management of volume overload should be prescribed ACE inhibitors or ARBs and beta-blockers titrated to attain SBP &lt;130 mmHg.</li> </ul> <p><u>CKD</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and CKD should be treated to a BP goal &lt;130/80 mmHg.</li> <li>• In adults with hypertension and CKD [stage 3 or higher or stage 1 or 2 with albuminuria (<math>\geq 300</math> mg/d, or <math>\geq 300</math> mg/g albumin-to-creatinine ratio or the equivalent in the first morning void)], treatment with an ACE inhibitor is reasonable to slow kidney disease progression. Treatment with an ARB may be reasonable if an ACE inhibitor is not tolerated.</li> <li>• After kidney transplantation, it is reasonable to treat patients with hypertension to a BP goal &lt;130/80 mmHg and with a CCB on the basis of improved glomerular filtration rate (GFR) and kidney survival.</li> </ul> <p><u>Cerebrovascular Disease</u></p> <ul style="list-style-type: none"> <li>• In adults with intracerebral hemorrhage (ICH) who present with SBP &gt;220 mmHg, it is reasonable to use continuous intravenous (IV) drug infusion and close BP monitoring to lower levels. Immediate lowering of SBP to &lt;140 mmHg in adults with spontaneous ICH who present within six hours of the acute event and have an SBP between 150 mmHg and 220 mmHg is not of benefit to reduce death or severe disability and can be potentially harmful.</li> <li>• Adults with acute ischemic stroke and elevated BP who are eligible for treatment with IV tissue plasminogen activator (tPA) should have their BP slowly lowered to &lt;185/110 mmHg before thrombolytic therapy is initiated.</li> <li>• In adults with an acute ischemic stroke, BP should be &lt;185/110 mmHg before administration of IV tPA and should be maintained below 180/105 mmHg for at least the first 24 hours after initiation drug therapy.</li> <li>• Starting or restarting antihypertensive therapy during hospitalization in patients with BP &gt;140/90 mmHg who are neurologically stable is safe and reasonable to improve long-term BP control, unless contraindicated.</li> <li>• In patient with BP <math>\geq 220/120</math> mmHg who did not receive IV alteplase or endovascular treatment and have no comorbid conditions requiring acute antihypertensive treatment, the benefit of initiating or reinitiating treatment of hypertension within the first 48 to 72 hours is uncertain. It might be reasonable to lower BP by 15% during the first 24 hours after onset of stroke. In patients with BP &lt;220/120 mmHg with the same conditions, initiating or reinitiating treatment of hypertension within the first 48 to 72 hours after an acute ischemic stroke is not effective to prevent death or dependency.</li> <li>• Adults with previously treated stroke or transient ischemic attack should be restarted on antihypertensive treatment after the first few days of the index event to reduce the risk of recurrent stroke and other vascular events. Treatment with a thiazide diuretic, ACE inhibitor, or ARB, or combination treatment consisting of</li> </ul>

Clinical Guideline	Recommendations
	<p>a thiazide diuretic plus ACE inhibitor, is useful.</p> <ul style="list-style-type: none"> <li>• Adults not previously treated for hypertension who experienced a stroke or transient ischemic attack and have an established BP <math>\geq 140/90</math> mmHg should be prescribed antihypertensive treatment a few days after the index event to reduce the risk of recurrent stroke and other vascular event.</li> <li>• For adults who experience a stroke or transient ischemic attack, selection of specific drugs should be individualized on the basis of patient comorbidities and agent pharmacological class.</li> <li>• For adults who experience a stroke or transient ischemic attack, a BP goal <math>&lt;130/80</math> mmHg may be reasonable.</li> <li>• For adults with a lacunar stroke, a target SBP goal <math>&lt;130</math> mmHg may be reasonable.</li> <li>• In adults previously untreated for hypertension who experience an ischemic stroke or transient ischemic attack and have an SBP <math>&lt;140</math> mmHg and a DBP <math>&lt;90</math> mmHg, the usefulness of initiating antihypertensive treatment is not well established.</li> </ul> <p><u>Peripheral Artery Disease (PAD)</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and PAD should be treated similarly to patients with hypertension without PAD.</li> </ul> <p><u>Diabetes Mellitus (DM)</u></p> <ul style="list-style-type: none"> <li>• In adults with DM and hypertension, antihypertensive drug treatment should be initiated at a BP of <math>\geq 130/80</math> mmHg with a treatment goal <math>&lt;130/80</math> mmHg.</li> <li>• In adults with DM and hypertension, all first-line classes of antihypertensive agents (i.e., diuretics, ACE inhibitors, ARBs, and CCBs) are useful and effective.</li> <li>• In adults with DM and hypertension, ACE inhibitors or ARBs may be considered in the presence of albuminuria.</li> </ul> <p><u>Atrial Fibrillation, Valvular Heart Disease, and Aortic disease</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension can be useful for prevention of recurrence of AF.</li> <li>• In adults with asymptomatic aortic stenosis, hypertension should be treated with pharmacotherapy, starting at a low dose and gradually titrating upward as needed.</li> <li>• In patients with chronic aortic insufficiency, treatment of systolic hypertension with agents that do not slow the heart rate (i.e., avoid beta-blockers) is reasonable.</li> <li>• Beta-blockers are recommended as the preferred antihypertensive agents in patients with hypertension and thoracic aortic disease.</li> </ul> <p><u>Racial and Ethnic Differences in Treatment</u></p> <ul style="list-style-type: none"> <li>• In black adults with hypertension but without HF or CKD, including those with DM, initial antihypertensive treatment should include a thiazide-type diuretic or CCB. Two or more antihypertensive medications are recommended to achieve a BP target <math>&lt;130/80</math> mmHg in most adults with hypertension, especially in black adults with hypertension.</li> </ul> <p><u>Pregnancy</u></p> <ul style="list-style-type: none"> <li>• Women with hypertension who become pregnant, or are planning to become pregnant, should be transitioned to methyldopa, nifedipine, and/or labetalol during pregnancy.</li> <li>• Women with hypertension who become pregnant should not be treated with ACE inhibitors, ARBs, or direct renin inhibitors.</li> </ul> <p><u>Older Persons</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension with an SBP treatment goal <math>&lt;130</math> mmHg is</li> </ul>

Clinical Guideline	Recommendations
	<p>recommended for noninstitutionalized ambulatory community-dwelling adults (<math>\geq 65</math> years of age) with an average SBP of <math>\geq 130</math> mmHg.</p> <ul style="list-style-type: none"> <li>For older adults (<math>\geq 65</math> years of age) with hypertension and a higher burden of comorbidity and limited life expectancy, clinical judgment, patient preference, and a team-based approach to assess risk/benefit is reasonable for decisions regarding intensity of BP lowering and choice of antihypertensive drugs.</li> </ul> <p><u>Hypertensive Crises</u></p> <ul style="list-style-type: none"> <li>In adults with a hypertensive emergency, admission to an intensive care unit is recommended for continuous monitoring of BP and target organ damage and for parenteral administration of an appropriate agent.</li> <li>For adults with a compelling condition (i.e., aortic dissection, severe pre-eclampsia or eclampsia, or pheochromocytoma crisis), SBP should be reduced to <math>&lt; 140</math> mmHg during the first hour and to <math>&lt; 120</math> mmHg in aortic dissection.</li> <li>For adults without a compelling condition, SBP should be reduced by no more than 25% within the first hours; then, if stable, to 160/100 mmHg within the next two to six hours; and then cautiously to normal during the following 24 to 48 hours.</li> </ul> <p><u>Cognitive Decline and Dementia</u></p> <ul style="list-style-type: none"> <li>In adults with hypertension, BP lowering is reasonable to prevent cognitive decline and dementia.</li> </ul> <p><u>Patients Undergoing Surgical Procedures</u></p> <ul style="list-style-type: none"> <li>In patients with hypertension undergoing major surgery who have been on beta-blockers chronically, beta-blockers should be continued.</li> <li>In patients with hypertension undergoing planned elective major surgery, it is reasonable to continue medical therapy for hypertension until surgery.</li> <li>In patients with hypertension undergoing major surgery, discontinuation of ACE inhibitors or ARBs perioperatively may be considered.</li> <li>In patients with planned elective major surgery and SBP <math>\geq 180</math> mmHg or DBP <math>\geq 110</math> mmHg, deferring surgery may be considered.</li> <li>For patients undergoing surgery, abrupt pre-operative discontinuation of beta-blockers or clonidine is potentially harmful.</li> <li>Beta-blockers should not be started on the day of surgery in beta-blocker-naïve patients.</li> <li>Patients with intraoperative hypertension should be managed with IV medications until such time as oral medications can be resumed.</li> </ul>

### III. Indications

The Food and Drug Administration (FDA)-approved indications for the central  $\alpha$ -agonists are noted in Table 3. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 3. FDA-Approved Indications for the Central Alpha-Agonists<sup>6-10</sup>**

Indication	Single Entity Agents		
	Clonidine	Guanfacine	Methyldopa
Treatment of hypertension	✓ *	✓ *	✓

\*Alone or in combination with other antihypertensive agents.

†This fixed combination drug is not indicated for the initial therapy of hypertension.

#### IV. Pharmacokinetics

The pharmacokinetic parameters of the central  $\alpha$ -agonists are listed in Table 4.

**Table 4. Pharmacokinetic Parameters of the Central Alpha-Agonists<sup>7</sup>**

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life (hours)
<b>Single Entity Agents</b>					
Clonidine	Oral: 75 to 100 TD: 60	20 to 40	Liver	Renal (40 to 60) Feces (22)	Oral: 22 TD: 12 to 13
Guanfacine	80	70	Liver	Renal (50)	17
Methyldopa	25 to 50	Negligible (% not reported)	Liver	Renal (70) Feces (30 to 50)	1.7

TD=transdermal

#### V. Drug Interactions

Significant drug interactions with the central  $\alpha$ -agonists are listed in Table 5.

**Table 5. Significant Drug Interactions with the Central Alpha-Agonists<sup>7</sup>**

Generic Name(s)	Interaction	Mechanism
Central $\alpha$ -agonists (clonidine)	Beta-adrenergic blockers	The severity of rebound hypertension associated with abrupt withdrawal of clonidine may be greater in patients taking $\beta$ -adrenergic blockers. This combination has also been reported to cause paradoxical hypertension. The mechanism of this interaction is unknown.
Central $\alpha$ -agonists (clonidine)	Tricyclic antidepressants	The antihypertensive effectiveness of clonidine may be decreased. Tricyclic antidepressants may also worsen the rebound reactions, such as hypertension and tachycardia, from abrupt clonidine withdrawal. The mechanism of this interaction is unknown.
Central $\alpha$ -agonists (clonidine)	Diltiazem, verapamil	Sinus bradycardia, AV block and severe hypotension may occur with coadministration of clonidine and diltiazem/verapamil. The mechanism of this interaction is unknown.
Central $\alpha$ -agonists (guanfacine)	Conivaptan	Concurrent use of conivaptan and guanfacine may result in increased guanfacine exposure due to CYP3A4 inhibition.
Central $\alpha$ -agonists (methyldopa)	Sympathomimetics	The coadministration of methyldopa and sympathomimetics may result in an increased pressor response, possibly resulting in hypertension.
Central $\alpha$ -agonists (methyldopa)	Entacapone	Concurrent use of entacapone and methyldopa may result in an increased risk of tachycardia, hypertension, and arrhythmias.
Central $\alpha$ -agonists (methyldopa)	Monoamine oxidase inhibitors	Metabolites of methyldopa stimulate release of endogenous catecholamines that are usually metabolized by MAOIs, thereby leading to excessive sympathetic stimulation.

## VI. Adverse Drug Events

The most common adverse drug events reported with the central  $\alpha$ -agonists are listed in Table 6. Abrupt discontinuation may cause nervousness, palpitations, headache, perspiration, nausea, and agitation. In some cases, sudden discontinuation may cause potentially dangerous rebound hypertension.<sup>6,7</sup>

## VII. Dosing and Administration

The usual dosing regimens for the central  $\alpha$ -agonists are listed in Table 7.

**Table 7. Usual Dosing Regimens for the Central Alpha-Agonists<sup>6-10</sup>**

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
<b>Single Entity Agents</b>			
Clonidine	<p><u>Hypertension:</u> Tablet: initial, 0.1 mg twice daily; maintenance, 0.1 to 0.6 mg/day in two divided doses; maximum, 2.4 mg/day</p> <p>Transdermal: initial, 0.1 mg patch once weekly; maintenance, 0.1 to 0.3 mg patch once weekly; maximum, two of the 0.3 mg patches once weekly</p>	Safety and effectiveness in pediatric patients have not been established in adequate and well-controlled trials.	<p>Tablet: 0.1 mg 0.2 mg 0.3 mg</p> <p>Transdermal patch: 0.1 mg/24 hours 0.2 mg/24 hours 0.3 mg/24 hours</p>
Guanfacine	<p><u>Hypertension:</u> Tablet: initial, 1 mg once daily at bedtime; maintenance, 1 to 2 mg once daily; maximum, 3 mg once daily</p>	Safety and efficacy in children under 12 have not been established.	Tablet: 1 mg 2 mg
Methyldopa	<p><u>Hypertension:</u> Tablet: initial, 250 mg 2 to 3 times daily; maintenance, 500 to 2,000 mg daily in two divided doses; maximum dose, 3 g daily</p>	<p>There are no well-controlled clinical trials in pediatric patients. Information on dosing in pediatric patients is supported by evidence from published literature regarding the treatment of hypertension in pediatric patients.</p> <p><u>Hypertension:</u> Tablet: initial, 10 mg/kg/day in 2 to 4 divided doses; maintenance, titrate up or down until adequate response achieved; maximum, 65 mg/kg/day or 3 g daily, whichever is less</p>	Tablet: 250 mg 500 mg

## VIII. Effectiveness

Clinical studies evaluating the safety and efficacy of the central  $\alpha$ -agonists are summarized in Table 8.

**Table 8. Comparative Clinical Trials with the Central Alpha-Agonists**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
Lilja M et al. <sup>19</sup> (1991)  Clonidine 0.1 mg tablets BID  vs  clonidine 0.2 mg transdermal patch QD	DB, DD, PC, RCT, XO  Patients with mild to moderate HTN	N=16  12 weeks	Primary: Change from baseline in supine SBP, standing SBP and heart rate  Secondary: Difference in primary endpoints between oral and transdermal clonidine	Primary: Clonidine transdermal patch reduced both supine SBP and DBP by 13/7 mm Hg (P<0.01 and P<0.01) and heart rate by 9 bpm (P<0.01). Oral clonidine reduced only supine SPB by 11 mm Hg (P<0.01).  In a standing position, clonidine transdermal patch reduced SBP and DBP by 14/9 mm Hg (P<0.01 and P<0.01) and heart rate by 9 bpm (P<0.01). Oral clonidine reduced only standing heart rate by 8 bpm (P<0.05).  Secondary: There were no differences reported in primary endpoints between clonidine transdermal patch and oral clonidine (P value not reported).
Houston et al. <sup>20</sup> (1993)  Clonidine transdermal 0.1 to 0.3 mg QD plus nifedipine 60 mg QD (single entity products)  vs  nifedipine 60 mg QD	OL, PC, PRO  Male and nonpregnant female patients between 18 and 75 years of age with mild to moderate HTN and inadequate response to nifedipine	N=42  8 weeks	Primary: Change in seated DBP to less than 90 mmHg at 8 weeks  Secondary: Not reported	Primary: Patients on combination therapy experienced a reduction of 16/14 mmHg in the mean seated blood pressure vs placebo (P<0.01) with mean seated blood pressure of 127/87 mmHg.  A reduction of 5/10 mmHg in the mean seated blood pressure was seen with combination therapy vs nifedipine monotherapy (P<0.01).  A reduction of 18/12 mmHg in the mean standing blood pressure was seen with combination therapy vs placebo (P<0.01).  A reduction of 9/9 mmHg in the mean standing blood pressure was seen with combination therapy vs nifedipine monotherapy (P<0.01).  Secondary: Not reported
Krieger et al. <sup>21</sup> (2018) ReHOT	OL, RCT  Patients with resistant	N=162  12 weeks	Primary: BP control (determined by office BP<140/90)	Primary: Compared with the spironolactone group, the clonidine group presented similar rates of achieving the primary end point (20.5 vs 20.8%, respectively; RR, 1.01; 95% CI, 0.55 to 1.88; P=1.00).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>Clonidine 0.1 mg BID (could be titrated to 0.2 or 0.3 mg BID)</p> <p>vs</p> <p>spironolactone 12.5 mg QD (could be titrated to 25 or 50 mg/ day)</p>	<p>hypertension (no office and ambulatory BP monitoring control, despite treatment with 3 drugs, including a diuretic, for 12 weeks)</p>		<p>and ambulatory 24-hour mean BP &lt;130/80)</p> <p>Secondary: BP control by each evaluation method, absolute BP reduction</p>	<p>Secondary: Secondary end point analysis showed similar office BP (33.3 vs 29.3%) and ambulatory BP monitoring (44 vs 46.2%) control for spironolactone and clonidine, respectively. However, spironolactone promoted greater decrease in 24-hour systolic and diastolic BP and diastolic daytime ambulatory BP than clonidine.</p>
<p>Boyles et al.<sup>22</sup> (1984)</p> <p>Methyldopa 250 to 800 mg/day and HCTZ 25 to 100 mg/day</p> <p>vs</p> <p>HCTZ 25 to 100 mg/day</p>	<p>OL, RCT</p> <p>Patients ≥59 years with isolated systolic HTN</p>	<p>N=21</p> <p>18 weeks</p>	<p>Primary: Changes in blood pressure from baseline</p> <p>Secondary: Not reported</p>	<p>Primary: At two weeks standing blood pressure fell from a mean of 166/90 mmHg at baseline to 164/88 mmHg with HCTZ monotherapy.</p> <p>At four weeks standing blood pressure fell from a mean of 164/88 mmHg at the end of the two week HCTZ monotherapy period to 145/81 mmHg at two weeks with combination therapy.</p> <p>At 18 weeks standing blood pressure fell from a mean of 166/90 mmHg at baseline to 132/80 mmHg with combination therapy.</p> <p>Secondary: Not reported</p>
<p>Channick et al.<sup>23</sup> (1981)</p> <p>Methyldopa 250 mg/day and HCTZ 15 mg/day</p> <p>vs</p> <p>chlorthalidone 50 mg/day and reserpine 0.25 mg/day</p>	<p>OL, RCT</p> <p>Patients with HTN</p>	<p>N=56</p> <p>12 weeks</p>	<p>Primary: Efficacy of blood pressure lowering to goal DBP ≤90 mmHg</p> <p>Secondary: Adverse effects</p>	<p>Primary: Goal DBP of ≤90 mmHg was reached in 91% of the chlorthalidone and reserpine group vs 55% in the methyldopa and HCTZ group (P&lt;0.001).</p> <p>Secondary: The incidence of adverse effects was 31% with chlorthalidone and reserpine vs 64% with methyldopa and HCTZ (P&lt;0.02).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>Finnerty et al.<sup>24</sup> (1979)</p> <p>Methyldopa 500 mg to 2,000 mg QD</p> <p>vs</p> <p>reserpine 0.125 mg to 0.25 mg QD</p> <p>vs</p> <p>propranolol 80 mg to 320 mg QD</p> <p>All patients received hydro-flumethiazide* 50 or 100 mg QD.</p>	<p>RCT, SB</p> <p>Patients with HTN unresponsive to hydroflumethiazide monotherapy</p>	<p>N=59</p> <p>9 weeks</p>	<p>Primary: Percentage of patients achieving a DBP &lt;90 mm Hg</p> <p>Secondary: Not reported</p>	<p>Primary: At trial endpoint, 20 patients (100%) receiving reserpine, 13 of the 19 patients (68.4%) receiving methyldopa and 16 of the 20 patients (80%) receiving propranolol achieved a DBP &lt;90 mm Hg (mean reductions and P values not reported).</p> <p>Secondary: Not reported</p>
<p>Fernandez et al.<sup>25</sup> (1980)</p> <p>Methyldopa 750 mg/day</p> <p>vs</p> <p>chlorothiazide 450 mg/day</p> <p>vs</p> <p>methyldopa and chlorothiazide 250-150 mg/day* (fixed-dose combination)</p>	<p>DB, PC, RCT, XO</p> <p>Patients with uncomplicated HTN</p>	<p>N=44</p> <p>4 weeks</p>	<p>Primary: Blood pressure lowering efficacy</p> <p>Secondary: Adverse effects</p>	<p>Primary: No significant differences in supine blood pressure for any treatment compared to placebo was observed (P value not reported). However, upright SBP, DBP and mean blood pressure were significantly lower with methyldopa and methyldopa and chlorothiazide compared to placebo (P&lt;0.05 for all).</p> <p>Secondary: Adverse effects were reported as infrequent (P value not reported).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
product)  vs  placebo				
Materson et al. <sup>26</sup> (1990)  Hydralazine 25, 50 or 100 mg BID  vs  methyldopa 250, 500 or 1,000 mg BID  vs  metoprolol 50, 100 or 200 mg BID  vs  reserpine 0.05, 0.10 or 0.25 mg QD  All patients received HCTZ 25 to 100 mg QD.	DB, MC, RCT  Men ≥60 years with HTN not currently receiving antihypertensive therapy and DBP 90 to 114 mm Hg and SBP <240 mm Hg or a DBP <100 mm Hg and a SBP <240 mm Hg if currently taking antihypertensive therapy and the blood pressure criteria was met after ≥2 weeks without medication	N=690  12 months	Primary: The average reduction in SBP and DBP, the number of patients achieving the goal blood pressure, the average change in heart rate  Secondary: The rates of drug intolerances, adverse effects	Primary: Across all four treatments, there was an additional average reduction in BP of 13.1/10.6 mm Hg. The average reduction in SBP from baseline to endpoint for hydralazine, methyldopa, metoprolol and reserpine were -11.5±10.1 (P<0.001), -15.0±13.7 (P<0.001), -13.0±15.4 (P<0.001) and -12.7±11.5 (P<0.001), respectively. There was no significant difference in SBP reductions among the different treatments (P=0.43). The average reduction in DBP from baseline to endpoint for hydralazine, methyldopa, metoprolol and reserpine were -11.3±5.9 (P<0.001), -10.6±6.3 (P<0.001), -10.6±6.7 (P<0.001) and -9.8±6.3 (P<0.001), respectively. There was no significant difference in DBP reductions among the different treatments (P=0.59).  The average change in heart rate from baseline to endpoint for hydralazine, methyldopa, metoprolol and reserpine were 1.4±10.5 (P value not significant), -1.6±9.3 (P value not significant), 15.9±11.9 (P<0.05) and -7.9±10.7 (P<0.05), respectively. There was a significant difference in change in heart rate among the different treatments (P<0.001).  The percentage of patients achieving the goal blood pressure at endpoint with hydralazine, methyldopa, metoprolol and reserpine were 85.3, 81.7, 76.9 and 72.3%, respectively (P=0.28).  Secondary: Drug intolerance, defined as adverse effects prompting dose reduction or discontinuation, was present in 23.3% of patients not achieving goal blood pressure compared to 2.8% of those who did (P<0.001). This was significant with hydralazine, methyldopa and metoprolol, but not with reserpine.  There were 27 (10%) treatment discontinuations due to adverse effects (hydralazine [n=3], methyldopa [n=8], metoprolol [n=9] and reserpine

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>[n=7]). There were two treatment discontinuations with methyldopa and one with reserpine due to depression.</p> <p>The overall incidence of volunteered moderate or severe adverse effects, not prompting treatment discontinuation, was significantly greater (P&lt;0.01) with methyldopa (31%) and hydralazine (25%) compared to reserpine (15%) or metoprolol (9%).</p>
<p>McAreevey et al.<sup>27</sup> (1984)</p> <p>Hydralazine 12.5 mg QD up to 100 mg BID</p> <p>vs</p> <p>labetalol 200 mg QD up to 1,600 mg BID</p> <p>vs</p> <p>methyldopa 125 mg QD up to 1,000 mg BID</p> <p>vs</p> <p>prazosin 0.5 mg QD up to 10 mg BID</p> <p>vs</p> <p>placebo</p> <p>Minoxidil as add on therapy was given to</p>	<p>DB, PG, RCT</p> <p>Patients with inadequately controlled HTN while receiving atenolol 100 mg/day and bendrofluazide* 5 mg/day</p>	<p>N=238</p> <p>6 months</p>	<p>Primary: Comparative safety and efficacy, target blood pressure &lt;140/95 mm Hg</p> <p>Secondary: Not reported</p>	<p>Primary: Target blood pressure was reached in 25% of patients receiving hydralazine, 23% of patients receiving minoxidil, 19% of patients receiving prazosin, 17% of patients receiving methyldopa and zero percent of patients receiving placebo (P values not reported).</p> <p>Labetalol had the highest withdrawal rate compared to the other treatments with 78% (P&lt;0.05). Minoxidil had the second highest withdrawal rate with 57% (P&lt;0.05), due to fluid retention. There were no significant differences in withdrawal rates among the other treatments.</p> <p>Secondary: Not reported</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>men only.</p> <p>Doses were titrated upward at 2-week intervals until target BP or maximum dose was reached.</p>

Impact on Physician Visits

A search of Medline and PubMed did not reveal data pertinent to this topic.

**IX. Cost**

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of ‘\$’ signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 10. Relative Cost of the Central Alpha-Agonists**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost
<b>Single Entity Agents</b>				
Clonidine	tablet, transdermal patch	Catapres-TTS®*	\$\$\$\$\$	\$ to \$\$
Guanfacine	tablet	N/A	N/A	\$
Methyldopa	tablet	N/A	N/A	\$

\*Generic is available in at least one dosage form or strength.  
HCTZ=hydrochlorothiazide, N/A=not available

**X. Conclusions**

The central alpha-agonists are approved for the treatment of hypertension, and all of the agents are available in a generic formulation.<sup>6-10</sup> There are several national and international organizations that have published guidelines on the treatment of hypertension. Most of the guidelines do not address the use of the central  $\alpha$ -agonists.<sup>1,11-18</sup> Thiazide-type diuretics are frequently recommended as initial therapy in patients with uncomplicated hypertension. According to the National Heart, Lung, and Blood Institute’s Eighth Report of The Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 8), thiazide-type diuretics should be utilized first-line for most patients with hypertension, either alone or in combination with another antihypertensive from a different medication class (e.g., ACE inhibitors, ARBs,  $\beta$ -blockers, calcium

channel blockers).<sup>1</sup> Several guidelines consistently recommend that the selection of an antihypertensive agent be based on compelling indications for use.<sup>1,11-18</sup> Methyldopa is safe and effective to use during pregnancy.<sup>12-13</sup>

There are limited head-to-head studies with the central  $\alpha$ -agonists. Clinical trials have compared combination therapy to monotherapy. In these studies, the more aggressive treatment regimen lowered systolic and diastolic blood pressure to a greater extent than the less-intensive treatment regimen.<sup>20,22</sup> There does not appear to be any difference in efficacy with the oral or transdermal formulations of clonidine.<sup>19</sup> According to treatment guidelines, most patients will need more than one antihypertensive agent to achieve blood pressure goals.<sup>1,11-18</sup> Certain guidelines note that that fixed combination antihypertensive medications can favor compliance and simplify medication regimens.<sup>12</sup> However, there are no prospective, randomized-controlled trials that have demonstrated better clinical outcomes with any central  $\alpha$ -agonist fixed-dose combination product compared to the coadministration of the individual components as separate formulations.

The most common adverse events reported with the central  $\alpha$ -agonists include dizziness, drowsiness, dry mouth, and somnolence. Abrupt discontinuation may cause nervousness, palpitations, headache, perspiration, nausea, and agitation. In some cases, sudden discontinuation may cause potentially dangerous rebound hypertension.<sup>6-10</sup>

There is insufficient evidence to support that one brand central alpha-agonist is safer or more efficacious than another. Formulations without a generic alternative should be managed through the medical justification portion of the prior authorization process.

Therefore, all brand central alpha-agonists within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

## **XI. Recommendations**

No brand central alpha-agonist is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Direct Vasodilators  
AHFS Class 240820  
May 4, 2022**

**I. Overview**

The direct vasodilators are approved for the treatment of heart failure and hypertension.<sup>1-4</sup> Hydralazine and minoxidil interfere with calcium movement within the vascular smooth muscle, which is responsible for initiating and maintaining the contractile state. They exert a peripheral vasodilating effect through a direct relaxation of vascular smooth muscle. This leads to decreased arterial blood pressure, decreased peripheral vascular resistance, as well as an increase in heart rate, stroke volume, and cardiac output. Hydralazine is available as a single entity product, as well as in combination with isosorbide dinitrate. Isosorbide dinitrate enters vascular smooth muscle and is converted to nitric oxide, which results in dilatation of peripheral arteries and veins. Dilatation of the veins promotes peripheral pooling of blood and decreases venous return to the heart. Dilatation of the arteries reduces systemic vascular resistance, systolic arterial pressure, and mean arterial pressure.<sup>1,2</sup> The exact mechanism of action of the fixed-dose combination product containing isosorbide dinitrate and hydralazine in the treatment of heart failure has not been established.<sup>3</sup>

The direct vasodilators that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. Hydralazine and minoxidil are available in a generic formulation. This class was last reviewed in February 2020.

**Table 1. Direct Vasodilators Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
<b>Single Entity Agents</b>			
Hydralazine	injection, tablet	N/A	hydralazine
Minoxidil	tablet	N/A	minoxidil
Nitroprusside	injection <sup>^</sup>	Nitropress <sup>®*</sup> , Nipride <sup>®</sup>	none
<b>Combination Products</b>			
Isosorbide dinitrate and hydralazine	tablet	BiDil <sup>®</sup>	none

\*Generic is available in at least one dosage form or strength.

<sup>^</sup>Product is primarily administered in an institution.

PDL=Preferred Drug List

N/A=Not available

**II. Evidence-Based Medicine and Current Treatment Guidelines**

Current treatment guidelines that incorporate the use of the direct vasodilators are summarized in Table 2.

**Table 2. Treatment Guidelines Using the Direct Vasodilators**

Clinical Guideline	Recommendations
Eighth Joint National Committee (JNC 8): <b>2014 Evidence-based Guideline for the Management of High Blood Pressure in Adults (2014)</b> <sup>5</sup>	<ul style="list-style-type: none"> <li>Pharmacologic treatment should be initiated in patients <math>\geq 60</math> years of age to lower blood pressure at systolic blood pressure <math>\geq 150</math> mm Hg or diastolic blood pressure <math>\geq 90</math> mm Hg and to a goal systolic blood pressure <math>&lt; 150</math> mm Hg and goal diastolic blood pressure <math>&lt; 90</math> mm Hg. Adjustment of treatment is not necessary if treatment results in lower blood pressure and treatment is well tolerated and without adverse effects on health or quality of life.</li> <li>In patients <math>&lt; 60</math> years of age, pharmacologic treatment should be initiated to lower blood pressure at diastolic blood pressure <math>\geq 90</math> mm Hg to a goal diastolic blood pressure <math>&lt; 90</math> mm Hg.</li> <li>In patients <math>&lt; 60</math> years of age, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure <math>\geq 150</math> mm Hg to a goal diastolic</li> </ul>

Clinical Guideline	Recommendations
	<p>blood pressure &lt;140 mm Hg.</p> <ul style="list-style-type: none"> <li>• For patients ≥18 years of age with chronic kidney disease or diabetes, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥140 mm Hg or diastolic blood pressure ≥90 mm Hg and to a goal systolic blood pressure &lt;140 mm Hg and goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• Initial antihypertensive treatment for the general nonblack population, including those with diabetes, should include thiazide-type diuretic, calcium channel blocker (CCB), ACE inhibitor, or ARB.</li> <li>• Initial antihypertensive treatment for the general black population, including those with diabetes, should include thiazide-type diuretic or CCB.</li> <li>• For patients ≥18 years of age with chronic kidney disease regardless of race or diabetes status, initial (or add-on) treatment should include an ACE inhibitor or ARB to improve kidney outcomes.</li> <li>• The main goal of antihypertensive treatment is to attain and maintain goal blood pressure.</li> <li>• If goal blood pressure is not attained within a month of treatment, the dose of the initial drug should be increased or second drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• If goal is not achieved with two drugs, a third drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• An ACE inhibitor and ARB should not be used together.</li> <li>• Antihypertensive classes can be used if the patient is unable to achieve goal blood pressure with three agents or had a contraindication to a preferred class.</li> <li>• If blood pressure is not able to be achieved or in complicated patients, referral to a hypertension specialist may be indicated.</li> </ul>
<p>International Society of Hypertension: <b>Global Hypertension Practice Guidelines (2020)</b><sup>6</sup></p>	<p><u>Lifestyle modifications</u></p> <ul style="list-style-type: none"> <li>• Lifestyle modification is the first line of antihypertensive treatment.</li> <li>• Salt reduction: Reduce salt added when preparing foods, and at the table. Avoid or limit consumption of high salt foods such as soy sauce, fast foods and processed food including breads and cereals high in salt.</li> <li>• Healthy diet: Eating a diet that is rich in whole grains, fruits, vegetables, polyunsaturated fats and dairy products and reducing food high in sugar, saturated fat and trans fats, such as the DASH diet.</li> <li>• Healthy drinks: Moderate consumption of coffee, green and black tea. Other beverages that can be beneficial include karkadé (hibiscus) tea, pomegranate juice, beetroot juice and cocoa.</li> <li>• Moderation of alcohol consumption: The recommended daily limit for alcohol consumptions is 2 standard drinks for men and 1.5 for women (10 g alcohol/standard drink). Avoid binge drinking.</li> <li>• Weight reduction: Body weight control is indicated to avoid obesity. Particularly abdominal obesity should be managed. Ethnic-specific cut-offs for BMI and waist circumference should be used. Alternatively, a waist-to-height ratio &lt;0.5 is recommended for all populations.</li> <li>• Smoking cessation: Smoking is a major risk factor for cardiovascular disease (CVD), COPD and cancer. Smoking cessation and referral to smoking cessation programs are advised.</li> <li>• Regular physical activity: Studies suggest that regular aerobic and resistance exercise may be beneficial for both the prevention and treatment of hypertension. Moderate intensity aerobic exercise (walking, jogging, cycling, yoga, or swimming) for 30 minutes on five to seven days per week Strength training also can help reduce blood pressure. Performance of resistance/strength exercises on two to three days per week.</li> <li>• Reduce stress and induce mindfulness: Stress should be reduced and mindfulness or meditation introduced into the daily routine.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Reduce exposure to air pollution and cold temperature: Evidence from studies support a negative effect of air pollution on blood pressure in the long-term.</li> </ul> <p><u>Pharmacological Treatment</u></p> <ul style="list-style-type: none"> <li>• Ideal characteristics of drug treatment               <ul style="list-style-type: none"> <li>○ Treatments should be evidence-based in relation to morbidity/mortality prevention.</li> <li>○ Use a once-daily regimen which provides 24-hour blood pressure control.</li> <li>○ Treatment should be affordable and/or cost-effective relative to other agents.</li> <li>○ Treatments should be well-tolerated.</li> <li>○ Evidence of benefits of use of the medication in populations to which it is to be applied.</li> </ul> </li> <li>• General scheme for drug treatment               <ul style="list-style-type: none"> <li>○ Lifestyle modification is the first line of antihypertensive treatment.</li> <li>○ Grade 1 hypertension (BP 140 to 159/ 90 to 99): Immediate drug treatment in high-risk patients or those with CVD, chronic kidney disease (CKD), diabetes mellitus (DM), or hypertension-mediated organ damage (HMOD). Drug treatment after three to six months of lifestyle intervention if BP still not controlled in low to moderate risk patients.</li> <li>○ Grade 2 hypertension (BP <math>\geq</math>160/100): Immediate drug treatment in all patients.</li> </ul> </li> <li>• Core drug-treatment strategy               <ul style="list-style-type: none"> <li>○ Step 1: Dual low-dose combination (ACE inhibitor or ARB plus dihydropyridine-calcium channel blockers (DHP-CCB)); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance; consider ACE/ARB plus DHP-CCB or DHP-CCB plus thiazide-like diuretics in black patients.</li> <li>○ Step 2: Dual full-dose combination (ACE inhibitor or ARB plus DHP-CCB); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance.</li> <li>○ Step 3: Triple combination (ACE/ARB plus DHP-CCB plus thiazide-like diuretic).</li> <li>○ Step 4, resistant hypertension: triple combination plus spironolactone or other drug, alternatives include amiloride, doxazosin, eplerenone, clonidine, or <math>\beta</math>-blocker. Caution with spironolactone or other potassium sparing diuretics when estimated GFR <math>&lt;</math>45 mL/min/1.73m<sup>2</sup> or K<sup>+</sup> <math>&gt;</math>4.5 mmol/L.</li> <li>○ Consider <math>\beta</math>-blockers at any treatment step when there is a specific indication for their use, e.g., heart failure, angina, post-MI, atrial fibrillation, or younger women planning pregnancy or pregnant.</li> </ul> </li> </ul>
<p>Hypertension Canada: 2020 Guidelines for the Prevention, Diagnosis, Risk Assessment, and Treatment of Hypertension in Adults and Children (2020)<sup>7</sup></p>	<p><u>Indications for drug therapy for adults with hypertension without compelling indications for specific agents</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive therapy should be prescribed for average diastolic blood pressure (DBP) measurements of <math>\geq</math>100 mmHg or average systolic blood pressure (SBP) measurements of <math>\geq</math>160 mmHg in patients without macrovascular target organ damage or other cardiovascular risk factors.</li> <li>• Antihypertensive therapy should be strongly considered for average DPB readings <math>\geq</math>90 mmHg or for average SBP readings <math>\geq</math>140 mmHg in the presence of macrovascular target organ damage or other independent cardiovascular risk</li> </ul>

Clinical Guideline	Recommendations
	<p>factors.</p> <ul style="list-style-type: none"> <li>• For high-risk patients, aged 50 years or older, with SBP levels <math>\geq 130</math> mmHg, intensive management to target a SBP <math>&lt; 120</math> mmHg should be considered. Patient selection for intensive management is recommended and caution should be taken in certain high-risk groups.</li> </ul> <p><u>Indications for drug therapy for adults with diastolic and with or without systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be with either monotherapy or single pill combination (SPC). <ul style="list-style-type: none"> <li>○ Recommended monotherapy choices are: <ul style="list-style-type: none"> <li>▪ A thiazide/thiazide-like diuretic, with longer-acting diuretics preferred;</li> <li>▪ A <math>\beta</math>-blocker (in patients <math>&lt; 60</math> years of age);</li> <li>▪ An angiotensin-converting enzyme (ACE) inhibitor (in nonblack patients);</li> <li>▪ An angiotensin receptor blocker (ARB); or</li> <li>▪ A long-acting calcium channel blocker (CCB).</li> </ul> </li> <li>○ Recommended SPC choices are those in which an ACE inhibitor is combined with a CCB, ARB with a CCB, or ACE inhibitor or ARB with a diuretic.</li> <li>○ Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> </ul> </li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line choices. Useful choices include a thiazide/thiazide-like diuretic or CCB with either: ACE inhibitor, ARB, or <math>\beta</math>-blocker. Caution should be exercised in combining a nondihydropyridine CCB and a <math>\beta</math>-blocker. The combination of an ACE inhibitor and an ARB is not recommended.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other antihypertensive drugs may be added.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated hypertension; <math>\beta</math>-blockers are not recommended as first-line therapy for uncomplicated hypertension in patients <math>\geq 60</math> years of age; and ACE inhibitors are not recommended as first-line therapy for uncomplicated hypertension in black patients. However, these agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Indications for drug therapy for adults with isolated systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be single-agent therapy with a thiazide/thiazide-like diuretic, a long-acting dihydropyridine CCB, or an ARB. If there are adverse effects, another drug from this group should be substituted. Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line options.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other classes of drugs (such as <math>\alpha</math>-blockers, ACE inhibitors, centrally acting agents, or nondihydropyridine CCBs) may be combined or substituted.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated isolated systolic hypertension; and <math>\beta</math>-blockers are not recommended as first-line therapy for isolated systolic hypertension in patients <math>\geq 60</math> years of age. However, both agents may be used in patients with certain comorbid conditions or in</li> </ul>

Clinical Guideline	Recommendations
	<p>combination therapy.</p> <p><u>Guidelines for hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• For most hypertensive patients with CAD, an ACE inhibitor or ARB is recommended.</li> <li>• For hypertensive patients with CAD, but without coexisting systolic heart failure, the combination of an ACE inhibitor and ARB is not recommended.</li> <li>• For high-risk hypertensive patients, when combination therapy is being used, choices should be individualized. The combination of an ACE inhibitor and a dihydropyridine CCB is preferable to an ACE inhibitor and a thiazide/thiazide-like diuretic in selected patients.</li> <li>• For patients with stable angina pectoris but without previous heart failure, myocardial infarction, or coronary artery bypass surgery, either a <math>\beta</math>-blocker or CCB can be used as initial therapy.</li> <li>• Short-acting nifedipine should not be used.</li> <li>• When decreasing SBP to target levels in patients with established CAD (especially if isolated systolic hypertension is present), be cautious when the DBP is <math>\leq 60</math> mmHg because of concerns that myocardial ischemia might be exacerbated, especially in patients with left ventricular hypertrophy (LVH).</li> </ul> <p><u>Guidelines for patients with hypertension who have had a recent myocardial infarction</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should include a <math>\beta</math>-blocker as well as an ACE inhibitor.</li> <li>• An ARB can be used if the patient is intolerant of an ACE inhibitor.</li> <li>• CCBs may be used in patients after myocardial infarction when <math>\beta</math>-blockers are contraindicated or not effective. Nondihydropyridine CCBs should not be used when there is heart failure, evidenced by pulmonary congestion on examination or radiography.</li> </ul> <p><u>Treatment of hypertension in association with heart failure</u></p> <ul style="list-style-type: none"> <li>• In patients with systolic dysfunction (ejection fraction <math>&lt;40\%</math>), ACE inhibitors and <math>\beta</math>-blockers are recommended for initial therapy. Aldosterone antagonists (mineralocorticoid receptor antagonists) may be combined in treatment for patients with a recent cardiovascular hospitalization, acute myocardial infarction, elevated B-type natriuretic peptide or N-terminal pro-B-type natriuretic peptide level, or New York Heart Association (NYHA) Class II-IV symptoms. Careful monitoring for hyperkalemia is recommended when combining an aldosterone antagonist with ACE inhibitor or ARB treatment. Other diuretics are recommended as additional therapy if needed. Beyond considerations of BP control, doses of ACE inhibitors or ARBs should be titrated to those reported to be effective in trials unless adverse effects become manifest.</li> <li>• An ARB is recommended if ACE inhibitors are not tolerated.</li> <li>• A combination of hydralazine and isosorbide dinitrate is recommended if ACE inhibitors and ARBs are contraindicated or not tolerated.</li> <li>• For hypertensive patients whose BP is not controlled, an ARB may be combined with an ACE inhibitor and other antihypertensive drug treatment. Careful monitoring should be used if combining an ACE inhibitor and an ARB because of potential adverse effects such as hypotension, hyperkalemia, and worsening renal function. Additional therapies may also include dihydropyridine CCBs.</li> <li>• An angiotensin receptor-neprilysin inhibitor (ARNI) should be used in place of an ACE inhibitor or ARB for patients with HFrEF (<math>&lt;40\%</math>) who remain symptomatic despite treatment with appropriate dose of guideline directed HF therapy. Eligible patients must have a serum potassium <math>&lt;5.2</math> mmol/L, an eGFR <math>\leq 30</math> mL/min/1.73m<sup>2</sup> and close surveillance of serum potassium and creatinine.</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Treatment of hypertension in association with stroke</u></p> <ul style="list-style-type: none"> <li>• BP management in acute ischemic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> <li>• BP management after acute ischemic stroke <ul style="list-style-type: none"> <li>○ Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack.</li> <li>○ After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently &lt;140/90 mmHg.</li> <li>○ Treatment with an ACE inhibitor and thiazide/thiazide-like diuretic combination is preferred.</li> <li>○ For patients with stroke, the combination of an ACE inhibitor and ARB is not recommended.</li> </ul> </li> <li>• BP management in hemorrhagic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> </ul> <p><u>Treatment of hypertension in association with LVH</u></p> <ul style="list-style-type: none"> <li>• Hypertensive patients with LVH should be treated with antihypertensive therapy to decrease the rate of subsequent cardiovascular events.</li> <li>• The choice of initial therapy can be influenced by the presence of LVH. Initial therapy can be drug treatment using ACE inhibitors, ARBs, long-acting CCBs, or thiazide/thiazide-like diuretics. Direct arterial vasodilators such as hydralazine or minoxidil should not be used.</li> </ul> <p><u>Treatment of hypertension in association with nondiabetic chronic kidney disease</u></p> <ul style="list-style-type: none"> <li>• Individualize BP targets in patients with chronic kidney disease. Consider intensive targets (SBP &lt;120 mmHg) in appropriate patients.</li> <li>• For patients with hypertension and proteinuric chronic kidney disease (urinary protein &gt;150 mg per 24 hours or albumin to creatinine ratio &gt;30 mg/mmol), initial therapy should be an ACE inhibitor or an ARB if there is intolerance to ACE inhibitors.</li> <li>• In most cases, combination therapy with other antihypertensive agents might be needed to reach target BP levels.</li> <li>• The combination of an ACE inhibitor and ARB is not recommended for patients with nonproteinuric chronic kidney disease.</li> </ul> <p><u>Treatment of hypertension in association with renovascular disease</u></p> <ul style="list-style-type: none"> <li>• Patients with hypertension attributable to atherosclerotic renal artery stenosis should be primarily medically managed because renal angioplasty and stenting offers no benefit over optimal medical therapy alone.</li> <li>• Renal artery angioplasty and stenting for atherosclerotic hemodynamically significant renal artery stenosis could be considered for patients with uncontrolled hypertension resistant to maximally tolerated pharmacotherapy, progressive renal function loss, and acute pulmonary edema.</li> <li>• Patients with confirmed renal fibromuscular dysplasia (FMD) should be referred to a hypertension specialist.</li> <li>• Renal artery angioplasty without stenting is recommended for treatment of FMD-related renal artery stenosis. Stenting is not recommended unless needed because of a periprocedural dissection. Surgical revascularization should be considered in cases of complex lesions less amendable to angioplasty, stenosis associated with complex aneurysm, and restenosis despite two unsuccessful attempts of angioplasty.</li> </ul> <p><u>Treatment of hypertension in association with diabetes mellitus</u></p> <ul style="list-style-type: none"> <li>• Persons with diabetes mellitus should be treated to attain SBP of &lt;130 mmHg</li> </ul>

Clinical Guideline	Recommendations
	<p>and DBP of &lt;80 mmHg.</p> <ul style="list-style-type: none"> <li>• For persons with cardiovascular or kidney disease, including microalbuminuria, or with cardiovascular risk factors in addition to diabetes and hypertension, an ACE inhibitor or an ARB is recommended as initial therapy.</li> <li>• For persons with diabetes and hypertension not included in other guidelines in this section, appropriate choices include (in alphabetical order): ACE inhibitors, ARBs, dihydropyridine CCBs, and thiazide/thiazide-like diuretics.</li> <li>• If target BP levels are not achieved with standard-dose monotherapy, additional antihypertensive therapy should be used. For persons in whom combination therapy with an ACE inhibitor is being considered, a dihydropyridine CCB is preferable to a thiazide/thiazide-like diuretic.</li> </ul> <p><u>Resistant hypertension</u></p> <ul style="list-style-type: none"> <li>• Resistant hypertension is defined as BP above target despite three or more BP-lowering drugs at optimal doses preferably including a diuretic (and usually a renin-angiotensin-aldosterone system blocker and a CCB).</li> <li>• Accurate office and out-of-office BP measurement is essential.</li> <li>• Other reasons for apparent resistant hypertension should be eliminated before diagnosing true resistant hypertension, including nonadherence, white coat effect, and secondary hypertension.</li> <li>• Pharmacotherapy with the additional use of spironolactone, bisoprolol, doxazosin, amiloride, eplerenone, or clonidine with the baseline regimen decreases BP significantly, with the greatest BP-lowering shown with spironolactone.</li> <li>• Patients with resistant hypertension should be referred to providers with expertise in diagnosis and management of hypertension.</li> </ul> <p><u>Hypertension and pediatrics</u></p> <ul style="list-style-type: none"> <li>• BP should be measured regularly in children three years of age or older; the auscultatory method is the gold-standard at present.</li> <li>• Initial therapy should be monotherapy, with an ACE inhibitor or ARB (not first-line in black children), or a long-acting dihydropyridine CCB.</li> <li>• The treatment goal is systolic and diastolic office BP and/or ABPM &lt; 95th percentile or &lt;90th percentile in children with risk factors or target organ damage.</li> <li>• Complex cases should be referred to an expert in pediatric hypertension.</li> </ul> <p><u>Hypertension and pregnancy</u></p> <ul style="list-style-type: none"> <li>• Up to 7% of pregnancies are complicated by a hypertensive disorder of pregnancy, and approximately 5% of women will have chronic hypertension when they become pregnant.</li> <li>• The prevalence of hypertension in pregnancy is expected to increase with women becoming pregnant later in their reproductive years and the increasing prevalence of cardiovascular comorbidities such as increased preconception body mass index and maternal diabetes.</li> <li>• The possibility of pregnancy should be considered when managing women with hypertension who are of reproductive age.</li> <li>• Preconception counselling should be offered to all women with hypertension who are considering pregnancy.</li> <li>• ACE inhibitor and ARB therapy should be avoided before conception and during pregnancy unless there is a compelling indication for their use (i.e., proteinuric kidney disease).</li> <li>• Hypertension during pregnancy can increase the risk of adverse maternal and fetal outcomes, including an increased risk of preeclampsia, placental abruption, prematurity, small for gestational age infants, stillbirth, and maternal renal and</li> </ul>

Clinical Guideline	Recommendations
	<p>retinal injury, thus generally requires involvement of an interdisciplinary team including obstetrical care providers.</p> <ul style="list-style-type: none"> <li>• Antihypertensive therapy is recommended for average SBP measurements of <math>\geq 140</math> mmHg or DBP measurements of <math>\geq 90</math> mmHg in pregnant women with chronic hypertension, gestational hypertension, or preeclampsia. Initial antihypertensive therapy should be monotherapy from the following first-line drugs: oral labetalol, oral methyldopa, long-acting oral nifedipine, or other oral <math>\beta</math>-blockers (acebutolol, metoprolol, pindolol, and propranolol). Other antihypertensive drugs can be considered as second-line drugs including: clonidine, hydralazine, and thiazide diuretics.</li> <li>• Women with severe hypertension with SBP <math>\geq 160</math> mmHg or DBP <math>\geq 110</math> mmHg in pregnancy or postpartum require urgent antihypertensive therapy because it is considered an obstetrical emergency.</li> <li>• Antihypertensive drugs used in breastfeeding women include: labetalol, methyldopa, long-acting nifedipine, enalapril, or captopril.</li> </ul>
<p>European Society of Hypertension/ European Society of Cardiology: <b>2018 Guidelines for the management of arterial hypertension (2018)</b><sup>8</sup></p>	<p><u>Treatment strategies and choice of antihypertensive drugs</u></p> <ul style="list-style-type: none"> <li>• Diuretics (including thiazides, chlorthalidone, and indapamide), <math>\beta</math>-blockers, calcium channel blocker (CCB), angiotensin-converting enzyme (ACE) inhibitors, and angiotensin receptor blockers (ARBs) are all suitable for the initiation and maintenance of antihypertensive treatment, either as monotherapy or in some combinations.</li> <li>• Some agents should be considered as the preferential choice in specific conditions because used in trials in those conditions or because of greater effectiveness in specific types of organ damage. Preferred combinations should comprise a renin-angiotensin system (RAS) blocker (either an ACE inhibitor or an ARB) with a CCB or diuretic.</li> <li>• It is recommended that beta-blockers are combined with any of the other major drug classes when there are specific clinical situations, e.g. angina, post-myocardial infarction, heart failure, or heart rate control.</li> <li>• Initiation of antihypertensive therapy with a two-drug combination may be considered in patients with markedly high baseline blood pressure (BP) or at high cardiovascular (CV) risk.</li> <li>• The combination of two antagonists of the RAS is not recommended and should be discouraged.</li> <li>• Other drug combinations should be considered and probably are beneficial in proportion to the extent of BP reduction. However, combinations that have been successfully used in trials may be preferable.</li> <li>• Combinations of two antihypertensive drugs at fixed doses in a single tablet may be recommended and favored, because reducing the number of daily pills improves adherence, which is low in patients with hypertension. Exceptions are frail older patients and those at low risk and with grade one hypertension (particularly if systolic BP is <math>&lt; 150</math> mmHg).</li> <li>• It is recommended that if BP is not controlled with a three-drug combination, treatment should be increased by the addition of spironolactone or, if not tolerated, other diuretics such as amiloride or higher doses of other diuretics, a beta-blocker, or an alpha-blocker.</li> </ul> <p><u>Treatment strategies in white-coat and masked hypertension</u></p> <ul style="list-style-type: none"> <li>• In white-coat hypertensives without additional risk factors, therapeutic intervention may be limited to lifestyle changes only, but this decision should be accompanied by close follow-up.</li> <li>• In white-coat hypertensives with a higher CV risk or hypertension-mediated organ damage, drug treatment may be considered in addition to lifestyle changes.</li> <li>• In masked hypertension, both lifestyle measures and antihypertensive drug</li> </ul>

Clinical Guideline	Recommendations
	<p>treatment should be considered, because this type of hypertension has been consistently found to have a CV risk very close to that of in- and out-of-office hypertension.</p> <ul style="list-style-type: none"> <li>• Antihypertensive drug up-titration should be considered in treated patients whose out-of-office BP is not controlled (i.e., masked uncontrolled hypertension), because of the high CV risk of these patients.</li> </ul> <p><u>Antihypertensive treatment strategies in the elderly</u></p> <ul style="list-style-type: none"> <li>• It is recommended that older patients (<math>\geq 65</math> years) are treated with the same recommendations in non-older patient population. In very old patients (<math>\geq 80</math> years), it may be appropriate to initiate treatment with monotherapy.</li> <li>• In all older patients, when combination therapy is used, it is recommended that this is initiated at the lowest available doses. In all older patients, and especially very old or frail patients, the possible occurrence of postural BP should be closely monitored and symptoms of possible hypotensive episodes checked by ambulatory blood pressure monitoring.</li> <li>• Unless required for concomitant diseases, loop diuretics and alpha-blockers should be avoided because of their association with injurious falls.</li> <li>• Renal function should be frequently assessed to detect possible increases in serum creatinine and reductions in estimated glomerular filtration rate (eGFR) as a result of BP-related reductions in renal perfusion.</li> <li>• When treated, BP should be lowered to a systolic value of 130 to 139 mmHg and a diastolic value of <math>&lt; 80</math> mmHg if tolerated. Treated values of <math>&lt; 130</math> mmHg should be avoided.</li> </ul> <p><u>Treatment strategies in hypertensive women</u></p> <ul style="list-style-type: none"> <li>• Hormone therapy and selective estrogen receptor modulators are not recommended and should not be used for primary or secondary prevention of CVD.</li> <li>• In women with gestational hypertension, pre-existing hypertension superimposed by gestational hypertension, or with hypertension and subclinical organ damage or symptoms, initiation of drug treatments is recommended when SBP is <math>\geq 140</math> mmHg or DBP <math>\geq 90</math> mmHg. In all other cases, initiation of drug treatment is recommended when SBP is <math>\geq 150</math> mmHg or DBP is <math>\geq 95</math> mmHg.</li> <li>• Methyldopa, labetalol, and CCBs are recommended as the drugs of choice for the treatment of hypertension in pregnancy.</li> <li>• ACE inhibitors, ARBs, or direct renin inhibitors are not recommended during pregnancy.</li> <li>• SBP <math>\geq 170</math> mmHg or DBP <math>\geq 110</math> mmHg in a pregnant woman is an emergency, and admission to hospital is recommended.</li> <li>• In severe hypertension, drug treatment with intravenous (IV) labetalol, oral methyldopa, or nifedipine is recommended.</li> <li>• The recommended treatment for hypertensive crisis is IV labetalol or nicardipine and magnesium.</li> <li>• In pre-eclampsia associated with pulmonary edema, nitroglycerin given as an IV infusion is recommended.</li> <li>• In women with gestational hypertension or mild-pre-eclampsia, delivery is recommended at 37 weeks.</li> <li>• It is recommended to expedite delivery in pre-eclampsia with adverse conditions, such as visual disturbances or hemostatic disorders</li> <li>• In women at high risk of pre-eclampsia, provided they are at low risk of gastrointestinal hemorrhage, treatment with low dose aspirin from 12 weeks until delivery may be considered.</li> <li>• Methyldopa, labetalol, and nifedipine should be considered preferential antihypertensive drugs in pregnancy. Intravenous labetalol or infusion of</li> </ul>

Clinical Guideline	Recommendations
	<p>nitroprusside should be considered in case of emergency (pre-eclampsia).</p> <p><u>Treatment strategies in patients with diabetes</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive drug treatment is recommended for people with diabetes when office BP is <math>\geq 140/90</math> mmHg.</li> <li>• A SBP goal <math>&lt; 130</math> mmHg is recommended in patients with diabetes and <math>&lt; 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg.</li> <li>• In older people, the target SBP range is 130 to 139 mmHg.</li> <li>• The DBP target in patients with diabetes is recommended to be <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• It is recommended to initiate treatment with a combination of a RAS blocker with a CCB or thiazide/thiazide-like diuretic.</li> <li>• It is recommended that individual drug choice takes comorbidities into account.</li> <li>• Simultaneous administration of two blockers of the RAS is not recommended and should be avoided in patients with diabetes.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with nephropathy</u></p> <ul style="list-style-type: none"> <li>• In patients with diabetic and non-diabetic CKD, it is recommended that an office BP of <math>\geq 140/90</math> mmHg be treated with lifestyle advice and BP-lowering medication.</li> <li>• In patients with diabetic or non-diabetic CKD, it is recommended to lower SBP to a range of 130 to 139 mmHg. And individualized treatments should be considered according to its tolerability and impact on renal function and electrolytes.</li> <li>• A combination of a RAS blocker with a CCB or a diuretic is recommended as initial therapy.</li> <li>• RAS blockers are more effective in reducing albuminuria than other antihypertensive agents, and are indicated in hypertensive patients in the presence of microalbuminuria or overt proteinuria.</li> <li>• Combination of two RAS blockers, though potentially more effective in reducing proteinuria, is not recommended.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with cerebrovascular disease</u></p> <ul style="list-style-type: none"> <li>• In patients with acute intracerebral hemorrhage, immediate BP lowering is not recommended for patients with SBP <math>&lt; 220</math> mmHg. In patients with SBP <math>\geq 220</math> mmHg, care acute BP lowering with IV therapy to <math>&lt; 180</math> mmHg should be considered.</li> <li>• In acute ischemic stroke, routine BP lowering with antihypertensive therapy is not recommended with the exceptions with the exceptions: in patients with acute ischemic stroke who are eligible for IV thrombolysis, BP should be carefully lowered and maintained at <math>&lt; 180/105</math> mmHg for at least the first 24 hours after thrombolysis; In patients with markedly elevated BP who do not receive fibrinolysis, drug therapy may be considered, based on clinical judgement, to reduce BP by 15% during the first 24 hours after the stroke onset.</li> <li>• In hypertensive patients with an acute cerebrovascular event, antihypertensive treatment is recommended immediately for transient ischemic attack (TIA) and after several days in ischemic stroke.</li> <li>• In all hypertensive patients with ischemic stroke or TIA, an SBP target range of 120 to 130 mmHg should be considered.</li> <li>• The recommended antihypertensive drug treatment strategy for stroke prevention is a RAS blocker plus a CCB or a thiazide-like diuretic.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with heart failure (HF) or left ventricular hypertrophy (LVH)</u></p> <ul style="list-style-type: none"> <li>• In hypertensive patients with heart failure (with reduced or preserved ejection</li> </ul>

Clinical Guideline	Recommendations
	<p>fraction), BP-lowering treatment should be considered if <math>\geq 140/90</math> mmHg.</p> <ul style="list-style-type: none"> <li>• In patients with HF<sub>r</sub>EF, it is recommended that BP-lowering treatment comprises an ACE inhibitor or ARB, and a beta-blocker and a diuretic and/or mineralocorticoid receptor antagonist (MRA) if required.</li> <li>• Dihydropyridine CCBs may be added if BP control is not achieved.</li> <li>• In patients with HF<sub>p</sub>EF, BP treatment threshold and target values should be the same as for HF<sub>r</sub>EF).</li> <li>• Because no specific drug has proven its superiority, all major agents can be used.</li> <li>• In all patients with LVH, it is recommended to treat with a RAS blocker or in combination with a CCB or diuretic and SBP should be lowered to a range of 120 to 130 mmHg.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• In patients with CAD receiving BP-lowering drugs, it is recommended to target SBP to <math>\leq 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg. In older patients, the target is an SBP range of 130 to 140 mmHg. The target DBP is <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• In hypertensive patients with a history of myocardial infarction, beta-blockers and RAS blockers are recommended as part of treatment.</li> <li>• In patients with asymptomatic angina, beta-blockers and/or CCBs are recommended.</li> </ul>
<p>National Institute for Health and Clinical Excellence: <b>Hypertension in adults: diagnosis and management (2019)</b><sup>9</sup></p>	<p><u>Choosing antihypertensive drug treatment (for people with or without type II diabetes)</u></p> <ul style="list-style-type: none"> <li>• Where possible, recommend treatment with drugs taken only once a day.</li> <li>• Prescribe non-proprietary drugs where these are appropriate and minimize cost.</li> <li>• Offer people with isolated systolic hypertension (systolic blood pressure <math>\geq 160</math> mmHg) the same treatment as people with both raised systolic and diastolic blood pressure.</li> <li>• Offer antihypertensive drug treatment to women of child-bearing potential with diagnosed hypertension in line with recommendations in this guideline. For women considering pregnancy or who are pregnant or breastfeeding, manage hypertension in line with the recommendations on Management of pregnancy with chronic hypertension and Breastfeeding in 'Hypertension in pregnancy'.</li> <li>• When choosing antihypertensive drug treatment for adults of black African or African-Caribbean family origin, consider an angiotensin II receptor blocker, in preference to an angiotensin-converting enzyme inhibitor.</li> </ul> <p><u>Step one treatment</u></p> <ul style="list-style-type: none"> <li>• Patients <math>&lt; 55</math> years of age should be offered a step one antihypertensive with an angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB).</li> <li>• Offer an ACE inhibitor or an ARB to adults starting step 1 antihypertensive treatment who have type II diabetes and are of any age or family origin or those aged <math>&lt; 55</math> years but not of black African or African-Caribbean family origin.</li> <li>• If an ACE inhibitor is not tolerated, offer an ARB.</li> <li>• Do not combine an ACE inhibitor with an ARB for the treatment of hypertension.</li> <li>• Offer a calcium channel blocker (CCB) to adults starting step 1 antihypertensive treatment who are <math>&gt; 55</math> years of age and do not have diabetes and are of black African or African-Caribbean family origin and do not have type II diabetes and of any age.</li> <li>• If a CCB is not suitable, for example because of edema or intolerance, or if there is evidence of heart failure or a high risk of heart failure, offer a thiazide-like diuretic.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• If diuretic treatment is to be initiated or changed, offer a thiazide-like diuretic, such as indapamide in preference to a conventional thiazide diuretic such as bendroflumethiazide or hydrochlorothiazide.</li> <li>• For adults with hypertension who are already receiving treatment with bendroflumethiazide or hydrochlorothiazide, who have stable, well-controlled blood pressure, continue with their treatment.</li> </ul> <p><u>Step two treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering next step treatment for hypertension discuss with the person if they are taking their medicine as prescribed and support adherence in line with NICE's guideline on "Medicines adherence: involving patients decisions about prescribed medicines and supporting adherence".</li> <li>• If hypertension is not controlled with a step one treatment of an ACE inhibitor or ARB, offer choice of one of the following drugs in addition to the step one treatment: a CCB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults taking step one treatment of a CCB, offer the choice of one of the following drugs in addition to the step one treatment: an ACE inhibitor or an ARB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults of black African or African-Caribbean family origin who do not have type 2 diabetes taking step one treatment, consider an ARB, in preference to an ACE inhibitor, in addition to step one treatment.</li> </ul> <p><u>Step three treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering step three treatment, review the person's medications to ensure they are being taken at the optimal doses and discuss adherence (see recommendation under step two).</li> <li>• If hypertension is not controlled in adults taking step two treatment, offer a combination of an ACE inhibitor or ARB and a CCB and a thiazide-like diuretic.</li> </ul> <p><u>Step four treatment</u></p> <ul style="list-style-type: none"> <li>• If hypertension is not controlled in adults taking the optimal tolerated doses of an ACE inhibitor or an ARB plus a CCB and a thiazide-like diuretic, regard them as having resistant hypertension.</li> <li>• Before considering further treatment for a person with resistant hypertension, confirm elevated clinic blood pressure measurements using ambulatory or home blood pressure recordings, assess for postural hypotension, and discuss adherence.</li> <li>• For people with confirmed resistant hypertension, consider adding a fourth antihypertensive drug as step four treatment or seeking specialist advice.</li> <li>• Consider further diuretic therapy with low-dose spironolactone for adults with resistant hypertension starting step four treatment who have a blood potassium level of 4.5 mmol/l or less. Use particular caution in people with a reduced estimated glomerular filtration rate because they have an increased risk of hyperkalemia.</li> <li>• When using further diuretic therapy for step four treatment of resistant hypertension, monitor blood sodium and potassium and renal function within one month of starting treatment and repeat as needed thereafter.</li> <li>• Consider an alpha-blocker or beta-blocker for adults with resistant hypertension starting step four treatment who have a blood potassium level of more than 4.5 mmol/l.</li> <li>• If blood pressure remains uncontrolled in people with resistant hypertension taking the optimal tolerated doses of four drugs, seek specialist advice.</li> </ul>

Clinical Guideline	Recommendations
<p>International Society on Hypertension in Blacks: <b>Management of High Blood Pressure in Blacks (2010)</b><sup>10</sup></p>	<ul style="list-style-type: none"> <li>To attain and maintain blood pressure (BP) below target levels, multiple antihypertensive drugs will be required in most hypertensive blacks.</li> <li>Use of two-drug combination therapy when SBP is &gt;15 mm Hg and/or DBP is &gt;10 mm Hg above goal levels is increasingly recommended as first-line therapy.</li> <li>Two-drug regimens have generally contained a thiazide-type diuretic; however, the combination of a calcium channel blocker (CCB) with either an ACE inhibitor or an ARB has been shown equally efficacious in BP lowering but with demonstrated superiority (CCB+ACE) for hard clinical outcomes compared with the same ACE inhibitor plus a thiazide-type diuretic.</li> <li>In secondary prevention patients, the combination therapy should include a drug(s) with the appropriate compelling indications.</li> <li>Certain classes of antihypertensive medications, specifically diuretics and CCBs, lower BP on average more than <math>\beta</math>-blockers and renin-angiotensin system (RAS) blockers in black patients when used as monotherapies.</li> <li>In the absence of compelling indications, when BP is near goal levels, monotherapy with a diuretic or a CCB is preferred.</li> <li>Lifestyle modifications should be initiated in all patients with hypertension, whether or not pharmacotherapy is planned.</li> <li>ACE inhibitors or ARBs are recommended as alternative monotherapy options in the treatment of hypertension in blacks. The rationale for their lower tier monotherapy recommendation is because they have consistently achieved lesser average reductions in BP relative to that observed with monotherapy using either a diuretic or CCB.</li> </ul>
<p>Kidney Disease Improving Clinical Outcomes Group: <b>KDIGO Clinical Practice Guideline for the Management of Blood Pressure in Chronic Kidney Disease (2021)</b><sup>11</sup></p>	<p><u>Blood pressure measurement</u></p> <ul style="list-style-type: none"> <li>The Work Group recommends standardized office blood pressure (BP) measurement in preference to routine office BP measurements for the management of high BP in adults.</li> <li>The Work Group suggests that out-of-office BP measurements with ambulatory BP monitoring (ABPM) or home BP monitoring (HBPM) be used to complement standardized office BP readings for the management of high BP.</li> </ul> <p><u>Lifestyle interventions for lowering BP in patients with chronic kidney disease (CKD) not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests targeting a sodium intake &lt;2 grams of sodium per day (or &lt;90 mmol of sodium per day, or &lt;5 grams of sodium chloride per day) in patients with high BP and CKD.</li> <li>The Work Group suggests that patients with high BP and CKD be advised to undertake moderate-intensity physical activity for a cumulative duration of at least 150 minutes per week, or to a level compatible with their cardiovascular and physical tolerance.</li> </ul> <p><u>BP management in patients with CKD, with or without diabetes, not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests that adults with high BP and CKD be treated with a target systolic BP (SBP) of &lt;120 mmHg, when tolerated, using standardized office BP measurement.</li> <li>The Work Group recommends starting renin-angiotensin-system inhibitors (RASi) (angiotensin-converting enzyme inhibitor [ACEi] or angiotensin II receptor blocker [ARB]) for people with high BP, CKD, and severely increased albuminuria without diabetes.</li> <li>The Work Group suggests starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately increased albuminuria without diabetes.</li> <li>The Work Group recommends starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately-to-severely increased albuminuria with diabetes.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>The Work Group recommends avoiding any combination of ACEi, ARB, and direct renin inhibitor (DRI) therapy in patients with CKD, with or without diabetes.</li> </ul> <p><u>BP management in kidney transplant recipients</u></p> <ul style="list-style-type: none"> <li>Treat adult kidney transplant recipients with high BP to a target BP of &lt;130 mmHg systolic and &lt;80 mmHg diastolic using standardized office BP measurement.</li> <li>The Work Group recommends that a dihydropyridine calcium channel blocker (CCB) or an ARB be used as the first-line antihypertensive agent in adult kidney transplant recipients.</li> </ul> <p><u>BP management in children with CKD</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests that in children with CKD, 24-hour mean arterial pressure by ABPM should be lowered to &lt;50<sup>th</sup> percentile for age, sex, and height.</li> </ul>
<p>American Diabetes Association: <b>Standards of Medical Care in Diabetes (2022)</b><sup>12</sup></p>	<p><u>Hypertension/blood pressure control</u></p> <ul style="list-style-type: none"> <li>Blood pressure should be measured at every routine visit. When possible, patients found to have elevated blood pressure (<math>\geq 140/90</math>) should have blood pressure confirmed using multiple readings, including measurements on a separate day, to diagnose hypertension. Patients with blood pressure <math>\geq 180/110</math> and cardiovascular disease could be diagnosed with hypertension at a single visit.</li> <li>All hypertensive patients with diabetes should monitor their blood pressure at home.</li> <li>For patients with diabetes and hypertension, with diabetes and hypertension, blood pressure targets should be individualized through a shared decision-making process that addresses cardiovascular risk, potential adverse effects of antihypertensive medications, and patient preferences.</li> <li>For individuals with diabetes and hypertension at higher cardiovascular risk (existing atherosclerotic cardiovascular disease [ASCVD] or 10-year ASCVD risk <math>\geq 15\%</math>), a blood pressure target of &lt;130/80 mmHg may be appropriate, if it can be safely attained.</li> <li>For individuals with diabetes and hypertension at lower risk for cardiovascular disease (10-year atherosclerotic cardiovascular disease risk &lt;15%), treat to blood pressure target of &lt;140/90.</li> <li>In pregnant patients with diabetes and preexisting hypertension, a blood pressure target of 110 to 135/85 is suggested in the interest of reducing the risk for accelerated maternal hypertension and minimizing impaired fetal growth.</li> <li>For patients with blood pressure &gt;120/80, lifestyle intervention consists of weight loss when indicated, a Dietary Approaches to Stop Hypertension (DASH)-style eating pattern including reducing sodium and increasing potassium intake, moderation of alcohol intake, and increased physical activity.</li> <li>Patients with confirmed office-based blood pressure <math>\geq 140/90</math> mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of pharmacologic therapy to achieve blood pressure goals.</li> <li>Patients with confirmed office-based blood pressure <math>\geq 160/100</math> mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of two drugs or a single pill combination of drugs demonstrated to reduce cardiovascular events in patients with diabetes.</li> <li>Treatment for hypertension should include drug classes demonstrated to reduce cardiovascular events in patients with diabetes (ACE inhibitors, angiotensin receptor blockers, thiazide-like diuretics, or dihydropyridine calcium channel blockers). ACE inhibitors or angiotensin receptor blockers are recommended first-line therapy for hypertension in people with diabetes and coronary artery</li> </ul>

Clinical Guideline	Recommendations
	<p>disease.</p> <ul style="list-style-type: none"> <li>• Multiple-drug therapy is generally required to achieve blood pressure targets (but not a combination of ACE inhibitors and angiotensin receptor blockers).</li> <li>• An ACE inhibitor or angiotensin receptor blocker, at the maximum tolerated dose indicated for blood pressure treatment, is the recommended first-line treatment for hypertension in patients with diabetes and urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine or 30 to 299 mg/g creatinine. If one class is not tolerated, the other should be substituted.</li> <li>• For patients treated with an ACE inhibitor, angiotensin receptor blocker, or diuretic, serum creatinine/estimated glomerular filtration rate and serum potassium levels should be monitored at least annually.</li> <li>• Patients with hypertension who are not meeting blood pressure targets on three classes of antihypertensive medications (including a diuretic) should be considered for mineralocorticoid receptor antagonist therapy.</li> </ul> <p><b>Chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>• At least once a year, assess urinary albumin (e.g., spot urinary albumin-to-creatinine ratio) and estimated glomerular filtration rate in patients with type 1 diabetes with duration of five or more years and in all patients with type 2 diabetes.</li> <li>• Patients with diabetes and urinary albumin <math>\geq 300</math> mg/g creatinine and/ or an estimated glomerular filtration rate 30 to 60 mL/min/1.73 m<sup>2</sup> should be monitored twice annually to guide therapy.</li> <li>• Optimize glucose control to reduce the risk or slow the progression of chronic kidney disease (CKD).</li> <li>• For patients with type 2 diabetes and diabetic kidney disease, use of a sodium-glucose cotransporter 2 inhibitor in patients with an estimated glomerular filtration rate <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> and urinary albumin <math>\geq 300</math> mg/g creatinine is recommended to reduce CKD progression and cardiovascular events..</li> <li>• In patients with type 2 diabetes and CKD, consider use of sodium-glucose cotransporter 2 inhibitors additionally for cardiovascular risk reduction when estimated glomerular filtration rate and urinary albumin creatinine are <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> or <math>\geq 300</math> mg/g, respectively.</li> <li>• In patients with CKD who are at increased risk for cardiovascular events or CKD progression and are unable to use a sodium-glucose cotransporter 2 inhibitor, a nonsteroidal mineralocorticoid receptor antagonist (finerenone) is recommended to reduce CKD progression and cardiovascular events.</li> <li>• Optimize blood pressure control and reduce blood pressure variability to reduce the risk or slow the progression of CKD.</li> <li>• Do not discontinue renin-angiotensin system blockade for minor increases in serum creatinine (<math>\leq 30\%</math>) in the absence of volume depletion.</li> <li>• For people with nondialysis-dependent stage 3 or higher CKD, dietary protein intake should be a maximum of 0.8 g/kg body weight per day (the recommended daily allowance). For patients on dialysis, higher levels of dietary protein intake should be considered, since malnutrition is a major problem in some dialysis patients.</li> <li>• In nonpregnant patients with diabetes and hypertension, either an ACE inhibitor or an angiotensin receptor blocker is recommended for those with modestly elevated urinary albumin-to-creatinine ratio (30 to 299 mg/g creatinine) and is strongly recommended for those with urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine and/or estimated glomerular filtration rate <math>&lt; 60</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Periodically monitor serum creatinine and potassium levels for the development of increased creatinine or changes in potassium when ACE inhibitors, angiotensin receptor blockers, or diuretics are used.</li> <li>• An ACE inhibitor or an angiotensin receptor blocker is not recommended for</li> </ul>

Clinical Guideline	Recommendations
	<p>the primary prevention of CKD in patients with diabetes who have normal blood pressure, normal urinary albumin-to-creatinine ratio (&lt;30 mg/g creatinine), and normal estimated glomerular filtration rate.</p> <ul style="list-style-type: none"> <li>• Patients should be referred for evaluation by a nephrologist if they have an estimated glomerular filtration rate &lt;30 mL/min/1.73 m<sup>2</sup>.</li> <li>• Promptly refer to a nephrologist for uncertainty about the etiology of kidney disease, difficult management issues, and rapidly progressing kidney disease.</li> </ul>
<p>American College of Cardiology/American Heart Association Task Force: <b>Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults</b> (2017)<sup>13</sup></p>	<p><u>Initiation of Blood Pressure (BP) Treatment for Overall Cardiovascular Disease (CVD) Risk</u></p> <ul style="list-style-type: none"> <li>• Use of BP-lowering medications is recommended for secondary prevention of recurrent CVD events in patients with clinical CVD and an average systolic blood pressure (SBP) ≥130 mmHg or an average diastolic blood pressure (DBP) of ≥80 mmHg and for primary prevention in adults with an estimated 10-year atherosclerotic cardiovascular disease (ASCVD) risk of ≥10% and an average SBP of ≥130 mmHg or an average ≥80 mmHg.</li> <li>• Use of BP-lowering medication is recommended for primary prevention of CVD in adults with no history of CVD and with an estimated 10-year ASCVD risk &lt;10% and an SBP of ≥140 mmHg or a DBP of ≥90 mmHg.</li> <li>• Simultaneous use of an angiotensin converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), and/or renin inhibitor is potentially harmful and is not recommended to treat adults with hypertension.</li> <li>• For adults with confirmed hypertension and known CVD or 10-year ASCVD risk of ≥10%, a BP target &lt;130/80 mmHg is recommended. For adults with confirmed hypertension without additional markers of increased CVD risk, a BP target &lt;130/80 mmHg may be reasonable.</li> <li>• For initiation of antihypertensive drug therapy, first-line agents include thiazide diuretics, calcium channel blockers (CCBs), and ACE inhibitors or ARBs.</li> <li>• Initiation of antihypertensive drug therapy with two first-line agents of different classes, either as separate agents or in a fixed-dose combination, is recommended in adults with stage 2 hypertension and an average BP &gt;20/10 mmHg above their BP target.</li> <li>• Initiation of antihypertensive drug therapy with a single antihypertensive drug is reasonable in adults with stage 1 hypertension and BP goal &lt;130/80 mmHg with dosage titration and sequential addition of other agents to achieve the BP target.</li> </ul> <p><u>Stable Ischemic Heart Disease (SIHD)</u></p> <ul style="list-style-type: none"> <li>• In adults with SIHD and hypertension, a BP target &lt;130/80 is recommended.</li> <li>• Adults with SIHD and hypertension (BP ≥130/80 mmHg) should be treated with medications [e.g., guideline-directed medical therapy (GDMT) beta-blockers, ACE inhibitors, or ARBs] for compelling indications [e.g., previous myocardial infarction (MI), stable angina] as first-line therapy, with the addition of other drugs (e.g., dihydropyridine CCBs, thiazide diuretics, and/or mineralocorticoid receptor antagonists) as needed to further control hypertension.</li> <li>• In adults with SIHD with angina and persistent uncontrolled hypertension, the addition of dihydropyridine CCBs to GDMT beta-blockers is recommended.</li> <li>• In adults who have had a MI or acute coronary syndrome, it is reasonable to continue GDMT beta-blockers beyond three years as long-term therapy for hypertension.</li> <li>• Beta-blockers and/or CCBs might be considered to control hypertension in patients with coronary artery disease (CAD) had an MI more than three years ago and have angina.</li> </ul> <p><u>Heart Failure</u></p> <ul style="list-style-type: none"> <li>• In adults with increased risk of HF, the optimal BP in those with hypertension</li> </ul>

Clinical Guideline	Recommendations
	<p>should be &lt;130 mmHg.</p> <ul style="list-style-type: none"> <li>• Adults with HFrEF and hypertension should be prescribed GDMT titrated to attain a BP &lt;130/80 mmHg.</li> <li>• Non-dihydropyridine CCBs are not recommended in the treatment of hypertension in adults with HFrEF.</li> <li>• In adults with HFpEF who present with symptoms of volume overload, diuretics should be prescribed to control hypertension.</li> <li>• Adults with HFpEF and persistent hypertension after management of volume overload should be prescribed ACE inhibitors or ARBs and beta-blockers titrated to attain SBP &lt;130 mmHg.</li> </ul> <p><u>CKD</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and CKD should be treated to a BP goal &lt;130/80 mmHg.</li> <li>• In adults with hypertension and CKD [stage 3 or higher or stage 1 or 2 with albuminuria (<math>\geq 300</math> mg/d, or <math>\geq 300</math> mg/g albumin-to-creatinine ratio or the equivalent in the first morning void)], treatment with an ACE inhibitor is reasonable to slow kidney disease progression. Treatment with an ARB may be reasonable if an ACE inhibitor is not tolerated.</li> <li>• After kidney transplantation, it is reasonable to treat patients with hypertension to a BP goal &lt;130/80 mmHg and with a CCB on the basis of improved glomerular filtration rate (GFR) and kidney survival.</li> </ul> <p><u>Cerebrovascular Disease</u></p> <ul style="list-style-type: none"> <li>• In adults with intracerebral hemorrhage (ICH) who present with SBP &gt;220 mmHg, it is reasonable to use continuous intravenous (IV) drug infusion and close BP monitoring to lower levels. Immediate lowering of SBP to &lt;140 mmHg in adults with spontaneous ICH who present within six hours of the acute event and have an SBP between 150 mmHg and 220 mmHg is not of benefit to reduce death or severe disability and can be potentially harmful.</li> <li>• Adults with acute ischemic stroke and elevated BP who are eligible for treatment with IV tissue plasminogen activator (tPA) should have their BP slowly lowered to &lt;185/110 mmHg before thrombolytic therapy is initiated.</li> <li>• In adults with an acute ischemic stroke, BP should be &lt;185/110 mmHg before administration of IV tPA and should be maintained below 180/105 mmHg for at least the first 24 hours after initiation drug therapy.</li> <li>• Starting or restarting antihypertensive therapy during hospitalization in patients with BP &gt;140/90 mmHg who are neurologically stable is safe and reasonable to improve long-term BP control, unless contraindicated.</li> <li>• In patient with BP <math>\geq 220/120</math> mmHg who did not receive IV alteplase or endovascular treatment and have no comorbid conditions requiring acute antihypertensive treatment, the benefit of initiating or reinitiating treatment of hypertension within the first 48 to 72 hours is uncertain. It might be reasonable to lower BP by 15% during the first 24 hours after onset of stroke. In patients with BP &lt;220/120 mmHg with the same conditions, initiating or reinitiating treatment of hypertension within the first 48 to 72 hours after an acute ischemic stroke is not effective to prevent death or dependency.</li> <li>• Adults with previously treated stroke or transient ischemic attack should be restarted on antihypertensive treatment after the first few days of the index event to reduce the risk of recurrent stroke and other vascular events. Treatment with a thiazide diuretic, ACE inhibitor, or ARB, or combination treatment consisting of a thiazide diuretic plus ACE inhibitor, is useful.</li> <li>• Adults not previously treated for hypertension who experienced a stroke or transient ischemic attack and have an established BP <math>\geq 140/90</math> mmHg should be prescribed antihypertensive treatment a few days after the index event to reduce</li> </ul>

Clinical Guideline	Recommendations
	<p>the risk of recurrent stroke and other vascular event.</p> <ul style="list-style-type: none"> <li>• For adults who experience a stroke or transient ischemic attack, selection of specific drugs should be individualized on the basis of patient comorbidities and agent pharmacological class.</li> <li>• For adults who experience a stroke or transient ischemic attack, a BP goal &lt;130/80 mmHg may be reasonable.</li> <li>• For adults with a lacunar stroke, a target SBP goal &lt;130 mmHg may be reasonable.</li> <li>• In adults previously untreated for hypertension who experience an ischemic stroke or transient ischemic attack and have an SBP &lt;140 mmHg and a DBP &lt;90 mmHg, the usefulness of initiating antihypertensive treatment is not well established.</li> </ul> <p><u>Peripheral Artery Disease (PAD)</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and PAD should be treated similarly to patients with hypertension without PAD.</li> </ul> <p><u>Diabetes Mellitus (DM)</u></p> <ul style="list-style-type: none"> <li>• In adults with DM and hypertension, antihypertensive drug treatment should be initiated at a BP of <math>\geq 130/80</math> mmHg with a treatment goal &lt;130/80 mmHg.</li> <li>• In adults with DM and hypertension, all first-line classes of antihypertensive agents (i.e., diuretics, ACE inhibitors, ARBs, and CCBs) are useful and effective.</li> <li>• In adults with DM and hypertension, ACE inhibitors or ARBs may be considered in the presence of albuminuria.</li> </ul> <p><u>Atrial Fibrillation, Valvular Heart Disease, and Aortic disease</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension can be useful for prevention of recurrence of AF.</li> <li>• In adults with asymptomatic aortic stenosis, hypertension should be treated with pharmacotherapy, starting at a low dose and gradually titrating upward as needed.</li> <li>• In patients with chronic aortic insufficiency, treatment of systolic hypertension with agents that do not slow the heart rate (i.e., avoid beta-blockers) is reasonable.</li> <li>• Beta-blockers are recommended as the preferred antihypertensive agents in patients with hypertension and thoracic aortic disease.</li> </ul> <p><u>Racial and Ethnic Differences in Treatment</u></p> <ul style="list-style-type: none"> <li>• In black adults with hypertension but without HF or CKD, including those with DM, initial antihypertensive treatment should include a thiazide-type diuretic or CCB. Two or more antihypertensive medications are recommended to achieve a BP target &lt;130/80 mmHg in most adults with hypertension, especially in black adults with hypertension.</li> </ul> <p><u>Pregnancy</u></p> <ul style="list-style-type: none"> <li>• Women with hypertension who become pregnant, or are planning to become pregnant, should be transitioned to methyldopa, nifedipine, and/or labetalol during pregnancy.</li> <li>• Women with hypertension who become pregnant should not be treated with ACE inhibitors, ARBs, or direct renin inhibitors.</li> </ul> <p><u>Older Persons</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension with an SBP treatment goal &lt;130 mmHg is recommended for noninstitutionalized ambulatory community-dwelling adults (<math>\geq 65</math> years of age) with an average SBP of <math>\geq 130</math> mmHg.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>For older adults (<math>\geq 65</math> years of age) with hypertension and a higher burden of comorbidity and limited life expectancy, clinical judgment, patient preference, and a team-based approach to assess risk/benefit is reasonable for decisions regarding intensity of BP lowering and choice of antihypertensive drugs.</li> </ul> <p><u>Hypertensive Crises</u></p> <ul style="list-style-type: none"> <li>In adults with a hypertensive emergency, admission to an intensive care unit is recommended for continuous monitoring of BP and target organ damage and for parenteral administration of an appropriate agent.</li> <li>For adults with a compelling condition (i.e., aortic dissection, severe pre-eclampsia or eclampsia, or pheochromocytoma crisis), SBP should be reduced to <math>&lt;140</math> mmHg during the first hour and to <math>&lt;120</math> mmHg in aortic dissection.</li> <li>For adults without a compelling condition, SBP should be reduced by no more than 25% within the first hours; then, if stable, to 160/100 mmHg within the next two to six hours; and then cautiously to normal during the following 24 to 48 hours.</li> </ul> <p><u>Cognitive Decline and Dementia</u></p> <ul style="list-style-type: none"> <li>In adults with hypertension, BP lowering is reasonable to prevent cognitive decline and dementia.</li> </ul> <p><u>Patients Undergoing Surgical Procedures</u></p> <ul style="list-style-type: none"> <li>In patients with hypertension undergoing major surgery who have been on beta-blockers chronically, beta-blockers should be continued.</li> <li>In patients with hypertension undergoing planned elective major surgery, it is reasonable to continue medical therapy for hypertension until surgery.</li> <li>In patients with hypertension undergoing major surgery, discontinuation of ACE inhibitors or ARBs perioperatively may be considered.</li> <li>In patients with planned elective major surgery and SBP <math>\geq 180</math> mmHg or DBP <math>\geq 110</math> mmHg, deferring surgery may be considered.</li> <li>For patients undergoing surgery, abrupt pre-operative discontinuation of beta-blockers or clonidine is potentially harmful.</li> <li>Beta-blockers should not be started on the day of surgery in beta-blocker-naïve patients.</li> <li>Patients with intraoperative hypertension should be managed with IV medications until such time as oral medications can be resumed.</li> </ul>
<p>American Heart Association/American College of Cardiology/Heart Failure Society of America: 2022 AHA/ACC/HFSA Guideline for the Management of Heart Failure (2022)<sup>14</sup></p>	<p><u>Treatment of Stage A heart failure (HF)</u></p> <ul style="list-style-type: none"> <li>Hypertension should be controlled in accordance with guideline-directed medication therapy for hypertension to prevent symptomatic HF. (LoE: A)</li> <li>In patients with type 2 diabetes and either established CVD or at high cardiovascular risk, SGLT-2 inhibitors should be used to prevent hospitalizations for HF. (LoE: A)</li> <li>In the general population, healthy lifestyle habits such as regular physical activity, maintaining normal weight, healthy dietary patterns, and avoiding smoking are helpful to reduce future risk of HF. (LoE: B)</li> <li>Patients at risk of developing HF, natriuretic peptide biomarker-based screening followed by team-based care, including a cardiovascular specialist optimizing therapy, can be useful to prevent the development of LV dysfunction (systolic or diastolic) or new-onset HF. (LoE: B)</li> </ul> <p><u>Treatment of Stage B heart failure</u></p> <ul style="list-style-type: none"> <li>In patients with LVEF <math>\leq 40\%</math>, ACE inhibitors should be used to prevent HF and reduce mortality. (LoE: A)</li> <li>In patients with a recent or remote history of MI or ACS, statins should be used to prevent symptomatic HF and adverse cardiovascular events. (LoE: A)</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In patients with a recent MI and LVEF≤40% who are intolerant to ACE inhibitors, ARB should be used to prevent symptomatic HF and reduce mortality. (LoE: B)</li> <li>• In patients with a recent or remote history of MI or ACS and LVEF≤40%, evidence-based beta blockers should be used to reduce mortality. (LoE: B)</li> <li>• In patients who are at least 40 days post-MI with LVEF ≤30% and NYHA class I symptoms while receiving guideline-directed medication therapy and have reasonable expectation of meaningful survival for greater than one year, an implantable cardioverter-defibrillator is recommended for primary prevention of sudden cardiac death to reduce total mortality. (LoE: B)</li> <li>• In patients with LVEF ≤40%, beta blockers should be used to prevent symptomatic HF. (LoE: C)</li> <li>• In patients with LVEF ≤50%, thiazolidinediones should not be used because they increase the risk of HF, including hospitalizations. (LoE: B)</li> <li>• In patients with LVEF ≤50%, nondihydropyridine calcium channel blockers with negative inotropic effects may be harmful. (LoE: C)</li> </ul> <p><b>Treatment for Stage C Heart Failure with Reduced Ejection Fraction (HFrEF)</b></p> <ul style="list-style-type: none"> <li>• For patients with stage C HF, avoiding excessive sodium intake is reasonable to reduce congestive symptoms. (LoE: C)</li> <li>• In patients with HF who have fluid retention, diuretics are recommended to relieve congestion, improve symptoms, and prevent worsening HF. (LoE: B)</li> <li>• For patients with HF and congestive symptoms, addition of a thiazide (e.g., metolazone) to treatment with a loop diuretic should be reserved for patients who do not respond to moderate or high dose loop diuretics to minimize electrolyte abnormalities. (LoE: B)</li> <li>• In patients with HFrEF and NYHA class II to III symptoms, the use of an ARNI is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, the use of an ACE inhibitor is beneficial to reduce morbidity and mortality when the use of an ARNI is not feasible. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, who are intolerant to an ACE inhibitor because of cough or angioedema, and when the use of an ARNI is not feasible, the use of an ARB is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with chronic symptomatic HFrEF NYHA class II or III who tolerate an ACE inhibitor or ARB, replacement by an ARNI is recommended to further reduce morbidity and mortality. (LoE: B)</li> <li>• ARNIs should not be administered concomitantly with ACE inhibitors or within 36 hours of the last dose of an ACE inhibitor. (LoE: B)</li> <li>• ARNI or ACE inhibitors should not be administered in patients with a history of angioedema. (LoE: C)</li> <li>• In patients with HFrEF, with current or previous symptoms, use of one of the three β-blockers proven to reduce mortality (e.g., bisoprolol, carvedilol, sustained-release metoprolol succinate) is recommended to reduce mortality and hospitalizations. (LoE: A)</li> <li>• In patients with HFrEF and NYHA class II to IV symptoms, a mineralocorticoid receptor antagonist (spironolactone or eplerenone) is recommended to reduce morbidity and mortality, if eGFR is &gt;30 mL/min/1.73 m<sup>2</sup> and serum potassium is &lt;5.0 mEq/L. Careful monitoring of potassium, renal function, and diuretic dosing should be performed at initiation and closely followed thereafter to minimize risk of hyperkalemia and renal insufficiency. (LoE: A)</li> <li>• In patients taking a mineralocorticoid receptor antagonist whose serum potassium cannot be maintained at &lt;5.5 mEq/L, mineralocorticoid receptor antagonist should be discontinued to avoid life threatening hyperkalemia. (LoE: A)</li> </ul>

Clinical Guideline	Recommendations
	<p>B)</p> <ul style="list-style-type: none"> <li>• In patients with symptomatic chronic HFrEF, SGLT-2 an inhibitor is recommended to reduce hospitalization for HF and cardiovascular mortality, irrespective of the presence of type 2 diabetes. (LoE: A)</li> <li>• The combination of hydralazine and isosorbide dinitrate is recommended to improve symptoms and reduce morbidity and mortality for patients self-identified as African Americans with NYHA class III to IV HFrEF receiving optimal therapy. (LoE: A)</li> <li>• In patients with current or previous symptomatic HFrEF who cannot be given first-line agents, such as an ARNI, ACE inhibitor or ARB because of drug intolerance or renal insufficiency, a combination of hydralazine and isosorbide dinitrate might be considered to reduce morbidity and mortality. (LoE: C)</li> <li>• In patients with HF class II to IV symptoms, omega-3 polyunsaturated fatty acid supplementation may be reasonable to use as adjunctive therapy to reduce mortality and cardiovascular hospitalizations. (LoE: B)</li> <li>• In patients with chronic HFrEF without specific indication (e.g., venous thromboembolism, atrial fibrillation, a previous thromboembolic event, or a cardioembolic source, anticoagulation is not recommended. (LoE: B)</li> <li>• Dihydropyridine and non-dihydropyridine calcium channel blockers are not recommended for patients with HFrEF. (LoE: A)</li> <li>• In patients with HFrEF, vitamins, nutritional supplements, and hormonal therapy are not recommended other than to correct specific deficiencies. (LoE: B)</li> <li>• In patients with HFrEF, class IC antiarrhythmic medication and dronedarone may increase risk of mortality. (LoE: A)</li> <li>• In patients with HFrEF, thiazolidinediones increase the risk of worsening HF symptoms and hospitalizations. (LoE: A)</li> <li>• In patients with type 2 diabetes and high cardiovascular risk, the DPP-4 inhibitors, saxagliptin and alogliptin, increase the risk of HF hospitalization and should be avoided in patients with HF. (LoE: B)</li> <li>• In patients with HFrEF, nonsteroidal anti-inflammatory drugs worsen HF symptoms and should be avoided or withdrawn whenever possible. (LoE: B)</li> <li>• For patients with symptomatic (NYHA class II to III) stable chronic HFrEF (LVEF <math>\leq</math>35%) who are receiving guideline-directed medical therapy, including a maximally tolerated dose of a beta blocker, and who are in sinus rhythm with a heart rate of <math>\geq</math>70 beats per minute at rest, ivabradine can be beneficial to reduce HF hospitalizations and cardiovascular death. (LoE: B)</li> <li>• In patients with symptomatic HFrEF despite guideline-directed medical therapy or who are unable to tolerate guideline-directed medical therapy, digoxin might be considered to decrease hospitalizations for HF. (LoE: B)</li> <li>• In select high-risk patients with HFrEF and recent worsening of HF already on guideline-directed medical therapy, an oral soluble guanylate cyclase stimulator (vericiguat) may be considered to reduce HF hospitalization and cardiovascular death. (LoE: B)</li> </ul> <p><b>Pharmacological treatment for Stage C HF with mildly reduced EF and improved EF</b></p> <ul style="list-style-type: none"> <li>• In patients with HF with mildly reduced EF, SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• Among patients with current or previous symptomatic HF with mildly reduced EF (LVEF, 41 to 49%), use of evidence-based beta blockers for HFrEF, ARNI, ACE inhibitor or ARB, and mineralocorticoid receptor antagonists may be considered to reduce the risk of HF hospitalization and cardiovascular mortality, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• In patients with HF with improved EF after treatment, guideline-directed</li> </ul>

Clinical Guideline	Recommendations
	<p>medical therapy should be continued to prevent relapse of HF and LV dysfunction, even in patients who may become asymptomatic. (LoE: B)</p> <p><u>Pharmacological treatment for Stage C HF with preserved EF (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• Patients with hypertension and HFpEF should have medication titrated to attain blood pressure targets in accordance with published clinical practice guidelines to prevent morbidity. (LoE: C)</li> <li>• SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• In patients with HFpEF, the use of a mineralocorticoid receptor antagonist, ARB, or ARNI may be considered to decrease hospitalizations, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• Routine use of nitrates or phosphodiesterase-5 inhibitors to increase activity or quality of life in patients with HFpEF is ineffective. (LoE: B)</li> </ul> <p><u>Treatment of Stage D (advanced/refractory) HF</u></p> <ul style="list-style-type: none"> <li>• For patients with advanced HF and hyponatremia, the benefit of fluid restriction to reduce congestive symptoms is uncertain. (LoE: C)</li> <li>• Continuous intravenous inotropic support is reasonable as “bridge therapy” in patients with HF (Stage D) refractory to guideline-directed medical therapy and device therapy who are eligible for and awaiting mechanical circulatory support or cardiac transplantation. (LoE: B)</li> <li>• In select patients with HF Stage D, despite optimal guideline-directed medical therapy and device therapy who are ineligible for either mechanical circulatory support or cardiac transplantation, continuous intravenous inotropic support may be considered as palliative therapy for symptom control and improvement in functional status. (LoE: B)</li> <li>• Long-term use of either continuous or intermittent, intravenous inotropic agents, for reasons other than palliative care or as a bridge to advanced therapies, is potentially harmful. (LoE: B)</li> </ul>
<p>American College of Cardiology Foundation/American Heart Association: <b>2014 American Heart Association/ American College of Cardiology Foundation Guideline for the Management of Patients With Non–ST-Elevation Acute Coronary Syndromes (2014)</b><sup>15</sup></p>	<p><u>Early hospital care- standard medical therapies</u></p> <ul style="list-style-type: none"> <li>• Supplemental oxygen should be administered to patients with non-ST-elevation acute coronary syndrome (NSTEMI-ACS) with arterial oxygen saturation &lt;90%, respiratory distress, or other high risk features of hypoxemia.</li> <li>• Anti-ischemic and analgesic medications <ul style="list-style-type: none"> <li>○ Nitrates <ul style="list-style-type: none"> <li>▪ Patients with NSTEMI-ACS with continuing ischemic pain should receive sublingual nitroglycerin (0.3 to 0.4 mg) every 5 minutes for up to three doses, after which an assessment should be made about the need for intravenous nitroglycerin.</li> <li>▪ Intravenous nitroglycerin is indicated for patients with NSTEMI-ACS for the treatment of persistent ischemia, heart failure, or hypertension.</li> <li>▪ Nitrates should not be administered to patients who recently received a phosphodiesterase inhibitor, especially within 24 hours of sildenafil or vardenafil, or within 48 hours of tadalafil.</li> </ul> </li> <li>○ Analgesic therapy <ul style="list-style-type: none"> <li>▪ In the absence of contraindications, it may be reasonable to administer morphine sulphate intravenously to patients with NSTEMI-ACE if there is continued ischemic chest pain despite treatment with maximally tolerated anti-ischemic medications.</li> <li>▪ Nonsteroidal anti-inflammatory drugs (NSAIDs) (except aspirin) should not be initiated and should be discontinued during hospitalization due to the increased risk of major adverse cardiac event associated with their use</li> </ul> </li> <li>○ Beta-adrenergic blockers <ul style="list-style-type: none"> <li>▪ Oral <math>\beta</math>-blocker therapy should be initiated within the first 24 hours in</li> </ul> </li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>patients who do not have any of the following: 1) signs of HF, 2) evidence of low-output state, 3) increased risk for cardiogenic shock, or 4) other contraindications to <math>\beta</math>-blockade (e.g., PR interval <math>&gt;0.24</math> second, second- or third-degree heart block without a cardiac pacemaker, active asthma, or reactive airway disease)</p> <ul style="list-style-type: none"> <li>▪ In patients with concomitant NSTEMI-ACS, stabilized heart failure, and reduced systolic function, it is recommended to continue <math>\beta</math>-blocker therapy with one of the three drugs proven to reduce mortality in patients with heart failure: sustained-release metoprolol succinate, carvedilol, or bisoprolol.</li> <li>▪ Patients with documented contraindications to <math>\beta</math>-blockers in the first 24 hours should be re-evaluated to determine subsequent eligibility.</li> </ul> <ul style="list-style-type: none"> <li>○ Calcium channel blockers (CCBs) <ul style="list-style-type: none"> <li>▪ In patients with NSTEMI-ACS, continuing or frequently recurring ischemia, and a contraindication to <math>\beta</math>-blockers, a nondihydropyridine CCB (e.g., verapamil or diltiazem) should be given as initial therapy in the absence of clinically significant LV dysfunction, increased risk for cardiogenic shock, PR interval <math>&gt;0.24</math> seconds, or second or third degree atrioventricular block without a cardiac pacemaker.</li> <li>▪ Oral nondihydropyridine calcium antagonists are recommended in patients with NSTEMI-ACS who have recurrent ischemia in the absence of contraindications, after appropriate use of <math>\beta</math>-blockers and nitrates.</li> <li>▪ CCBs are recommended for ischemic symptoms when <math>\beta</math>-blockers are not successful, are contraindicated, or cause unacceptable side effects.</li> <li>▪ Long-acting CCBs and nitrates are recommended in patients with coronary artery spasm.</li> <li>▪ Immediate-release nifedipine should not be administered to patients with NSTEMI-ACS in the absence of <math>\beta</math>-blocker therapy.</li> </ul> </li> <li>○ Other anti-ischemic interventions <ul style="list-style-type: none"> <li>▪ Ranolazine is currently indicated for treatment of chronic angina; however, it may also improve outcomes in NSTEMI-ACS patients due to a reduction in recurrent ischemia.</li> </ul> </li> <li>○ Cholesterol management <ul style="list-style-type: none"> <li>▪ High-intensity statin therapy should be initiated or continued in all patients with NSTEMI-ACS and no contraindications to its use. Treatment with statins reduces the rate of recurrent MI, coronary heart disease mortality, need for myocardial revascularization, and stroke.</li> <li>▪ It is reasonable to obtain a fasting lipid profile in patients with NSTEMI-ACS, preferably within 24 hours of presentation.</li> </ul> </li> <li>● Inhibitors of renin-angiotensin-aldosterone system <ul style="list-style-type: none"> <li>○ ACE inhibitors should be started and continued indefinitely in all patients with LVEF <math>&lt;0.40</math> and in those with hypertension, diabetes mellitus, or stable CKD, unless contraindicated.</li> <li>○ ARBs are recommended in patients with heart failure or myocardial infarction with LVEF <math>&lt;0.40</math> who are ACE inhibitor intolerant.</li> <li>○ Aldosterone-blockade is recommended in patients post-MI without significant renal dysfunction (creatinine <math>&gt;2.5</math> mg/dL in men or <math>&gt;2.0</math> mg/dL in women) or hyperkalemia (<math>K &gt;5.0</math> mEq/L) who are receiving therapeutic doses of ACE inhibitor and <math>\beta</math>-blocker and have a LVEF <math>&lt;0.40</math>, diabetes mellitus, or heart failure.</li> </ul> </li> <li>● Initial antiplatelet/anticoagulant therapy in patients with definite or likely NSTEMI-ACS treated with an initial invasive or ischemia-guided strategy <ul style="list-style-type: none"> <li>○ Non-enteric coated, chewable aspirin (162 to 325 mg) should be given to all patients with NSTEMI-ACS without contraindications as soon as possible after presentation, and a maintenance dose of aspirin (81 to 162 mg/day) should be continued indefinitely.</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>○ In patients who are unable to take aspirin because of hypersensitivity or major gastrointestinal intolerance, a loading dose of clopidogrel followed by a daily maintenance dose should be administered.</li> <li>○ A P2Y<sub>12</sub> receptor inhibitor (clopidogrel or ticagrelor) in addition to aspirin should be administered for up to 12 months to all patients with NSTEMI-ACS without contraindications who are treated with an early invasive or ischemia-guided strategy. Options include: <ul style="list-style-type: none"> <li>▪ Clopidogrel: 300 or 600 mg loading dose, then 75 mg daily.</li> <li>▪ Ticagrelor: 180 mg loading dose, then 90 mg twice daily.</li> <li>▪ It is reasonable to use ticagrelor in preference to clopidogrel for P2Y<sub>12</sub> treatment in patients with NSTEMI-ACS who undergo an early invasive or ischemia-guided strategy.</li> <li>▪ In patients with NSTEMI-ACS treated with an early invasive strategy and dual antiplatelet therapy (DAPT) with intermediate/high-risk features (e.g., positive troponin), a GP IIb/IIIa inhibitor may be considered as part of initial antiplatelet therapy. Preferred options are eptifibatid or tirofiban.</li> <li>▪ Fibrinolytic therapy in patients with definite NSTEMI-ACS</li> </ul> </li> </ul> <p><u>Percutaneous coronary intervention (PCI)- Antiplatelet and anticoagulant therapy</u></p> <ul style="list-style-type: none"> <li>● Antiplatelet agents <ul style="list-style-type: none"> <li>○ Patients already taking daily aspirin before PCI should take 81 to 325 mg non-enteric coated aspirin before PCI</li> <li>○ Patients not on aspirin therapy should be given non-enteric coated aspirin 325 mg as soon as possible before PCI.</li> <li>○ After PCI, aspirin should be continued indefinitely.</li> <li>○ A loading dose of a P2Y<sub>12</sub> inhibitor should be given before the procedure in patients undergoing PCI with stenting. Options include clopidogrel 600 mg, prasugrel 60 mg, or ticagrelor 180 mg.</li> <li>○ In patients with NSTEMI-ACS and high-risk features (e.g., elevated troponin) not adequately pretreated with clopidogrel or ticagrelor, it is useful to administer a GP IIb/IIIa inhibitor (abciximab, double-bolus eptifibatid, or high-dose bolus tirofiban) at the time of PCI.</li> <li>○ In patients receiving a stent (bare metal or drug eluting) during PCI, P2Y<sub>12</sub> inhibitor therapy should be given for at least 12 months. Options include clopidogrel 75 mg daily, prasugrel 10 mg daily, or ticagrelor 90 mg twice daily.</li> </ul> </li> <li>● Anticoagulant therapy <ul style="list-style-type: none"> <li>○ An anticoagulant should be administered to patients with NSTEMI-ACS undergoing PCI to reduce the risk of intracoronary and catheter thrombus formation.</li> <li>○ Intravenous unfractionated heparin (UFH) is useful in patients with NSTEMI-ACS undergoing PCI.</li> <li>○ Bivalirudin is useful as an anticoagulant with or without prior treatment with UFH.</li> <li>○ An additional dose of 0.3 mg/kg intravenous enoxaparin should be administered at the time of PCI to patients with NSTEMI-ACS who have received fewer than two therapeutic subcutaneous doses or received the last subcutaneous enoxaparin dose eight to 12 hours before PCI.</li> <li>○ If PCI is performed while the patient is on fondaparinux, an additional 85 IU/kg of UFH should be given intravenously immediately before PCI because of the risk of catheter thrombosis (60 IU/kg IV if a GP IIb/IIIa inhibitor used with UFH dosing based on the target-activated clotting time).</li> <li>○ Anticoagulant therapy should be discontinued after PCI unless there is a compelling reason to continue.</li> </ul> </li> <li>● Timing of CABG in relation to use of antiplatelet agents</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>○ Non-enteric coated aspirin (81 to 325 mg daily) should be administered preoperatively to patients undergoing CABG.</li> <li>○ In patients referred for elective CABG, clopidogrel and ticagrelor should be discontinued for at least five days before surgery and prasugrel for at least seven days before surgery.</li> <li>○ In patients referred for urgent CABG, clopidogrel and ticagrelor should be discontinued for at least 24 hours to reduce major bleeding.</li> <li>○ In patients referred for CABG, short-acting intravenous GP IIb/IIIa inhibitors (eptifibatide or tirofiban) should be discontinued for at least 2 to 4 hours before surgery and abciximab for at least 12 hours before to limit blood loss and transfusion.</li> </ul> <p><u>Late hospital care, hospital discharge, and posthospital discharge care</u></p> <ul style="list-style-type: none"> <li>● Medications at discharge <ul style="list-style-type: none"> <li>○ Medications required in the hospital to control ischemia should be continued after hospital discharge in patients with NSTEMI-ACS who do not undergo coronary revascularization, patients with incomplete or unsuccessful revascularization, and patients with recurrent symptoms after revascularization. Titration of the doses may be required.</li> <li>○ All patients who are post-NSTEMI-ACS should be given sublingual or spray nitroglycerin with verbal and written instructions for its use.</li> <li>○ Before hospital discharge, patients with NSTEMI-ACS should be informed about symptoms of worsening myocardial ischemia and MI and should be given verbal and written instructions about how and when to seek emergency care for such symptoms.</li> <li>○ Before hospital discharge, patients who are post-NSTEMI-ACS and/or designated responsible caregivers should be provided with easily understood and culturally sensitive verbal and written instructions about medication type, purpose, dose, frequency, side effects, and duration of use.</li> <li>○ For patients who are post-NSTEMI-ACS and have initial angina lasting more than one minute, nitroglycerin (one dose sublingual or spray) is recommended if angina does not subside within three to five minutes; call 9-1-1 immediately to access emergency medical services.</li> <li>○ If the pattern or severity of angina changes, suggesting worsening myocardial ischemia (e.g., pain is more frequent or severe or is precipitated by less effort or occurs at rest), patients should contact their clinician without delay to assess the need for additional treatment or testing.</li> <li>○ Before discharge, patients should be educated about modification of cardiovascular risk factors.</li> </ul> </li> <li>● Late hospital and post-hospital oral antiplatelet therapy <ul style="list-style-type: none"> <li>○ Aspirin should be continued indefinitely. The dose should be 81 mg daily in patients treated with ticagrelor and 81 to 325 mg daily in all other patients.</li> <li>○ In addition to aspirin, a P2Y<sub>12</sub> inhibitor (either clopidogrel or ticagrelor) should be continued for up to 12 months in all patients with NSTEMI-ACS without contraindications who are treated with an ischemia-guided strategy.</li> <li>○ In patients receiving a stent (bare-metal stent or DES) during PCI for NSTEMI-ACS, P2Y<sub>12</sub> inhibitor therapy should be given for at least 12 months.</li> </ul> </li> <li>● Combined oral anticoagulant therapy and antiplatelet therapy in patients with NSTEMI-ACS <ul style="list-style-type: none"> <li>○ The duration of triple antithrombotic therapy with a vitamin K antagonist, aspirin, and a P2Y<sub>12</sub> receptor inhibitor in patients with NSTEMI-ACS should be minimized to the extent possible to limit the risk of bleeding.</li> <li>○ Proton pump inhibitors should be prescribed in patients with NSTEMI-ACS with a history of gastrointestinal bleeding who require triple antithrombotic therapy with a vitamin K antagonist, aspirin, and a P2Y<sub>12</sub> receptor inhibitor.</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
<p>European Society of Cardiology: <b>Guidelines for the Management of Acute Coronary Syndromes in Patients Presenting without Persistent ST-Segment Elevation (2020)</b><sup>16</sup></p>	<p><u>Pharmacological treatment of ischemia</u></p> <ul style="list-style-type: none"> <li>• Sublingual or intravenous nitrates and early initiation of <math>\beta</math>-blocker treatment is recommended in patients with ongoing ischemic symptoms and without contraindications.</li> <li>• Continuation of chronic <math>\beta</math>-blocker therapy is recommended unless the patient is in overt heart failure</li> <li>• Sublingual or intravenous nitrates are recommended to relieve angina; intravenous treatment is recommended in patients with recurrent angina, uncontrolled hypertension, or signs of heart failure.</li> <li>• In patients with suspected/confirmed vasospastic angina, calcium channel blockers, and nitrates should be considered and <math>\beta</math>-blockers avoided.</li> </ul> <p><u>Recommendations for platelet inhibition in non-ST-elevation acute coronary syndromes</u></p> <ul style="list-style-type: none"> <li>• Aspirin is recommended for all patients without contraindications at an initial oral loading dose of 150 to 300 mg (in aspirin-naïve patients) and a maintenance dose of 75 to 100 mg/day long-term regardless of treatment strategy.</li> <li>• A P2Y<sub>12</sub> inhibitor is recommended, in addition to aspirin, for 12 months unless there are contraindications such as excessive risks of bleeds. <ul style="list-style-type: none"> <li>○ Ticagrelor (180 mg loading dose, 90 mg twice daily) is recommended, in the absence of contraindication, for all patients at moderate-to-high risk of ischemic events (e.g., elevated cardiac troponins), regardless of initial treatment strategy and including those pretreated with clopidogrel (which should be discontinued when ticagrelor is started).</li> <li>○ Prasugrel (60 mg loading dose, 10 mg daily dose) is recommended in patients who are proceeding to PCI if no contraindication. Prasugrel should be considered in preference to ticagrelor in NSTEMI-ACS patients who proceed to PCI.</li> <li>○ Clopidogrel (300 to 600 mg loading dose, 75 mg daily dose) is recommended for patients who cannot receive ticagrelor or prasugrel or who require oral anticoagulation.</li> </ul> </li> <li>• P2Y<sub>12</sub> inhibitor administration for a shorter duration of three to six months after DES implantation may be considered in patients deemed at high bleeding risk.</li> <li>• Pre-treatment with a P2Y<sub>12</sub> inhibitor may be considered in patients with NSTEMI-ACS who are not planned to undergo an early invasive strategy.</li> <li>• It is not recommended to administer routine pre-treatment with a P2Y<sub>12</sub> inhibitor in patients in whom coronary anatomy is not known.</li> <li>• It is not recommended to administer prasugrel in patients whom coronary anatomy is not known.</li> <li>• GPIIb/IIIa inhibitors during PCI should be considered for bailout situations or thrombotic complications.</li> <li>• Cangrelor may be considered in P2Y<sub>12</sub> inhibitor-naïve patients undergoing PCI.</li> <li>• It is not recommended to administer GPIIb/IIIa inhibitors in patients whom coronary anatomy is not known.</li> <li>• P2Y<sub>12</sub> inhibitor administration in addition to aspirin beyond one year may be considered after careful assessment of the ischemic and bleeding risks of the patient.</li> </ul> <p><u>Recommendations for anticoagulation in non-ST-elevation acute coronary syndromes</u></p> <ul style="list-style-type: none"> <li>• Parenteral anticoagulation is recommended at the time of diagnosis according to both ischemic and bleeding risks.</li> <li>• Fondaparinux is recommended as having the most favorable efficacy-safety profile regardless of the management strategy.</li> <li>• Bivalirudin is recommended as an alternative to UFH plus GPIIb/IIIa inhibitors</li> </ul>

Clinical Guideline	Recommendations
	<p>during PCI.</p> <ul style="list-style-type: none"> <li>• UFH is recommended in patients undergoing PCI who did not receive any anticoagulant.</li> <li>• In patients on fondaparinux undergoing PCI, a single intravenous bolus of UFH is recommended during the procedure.</li> <li>• Enoxaparin or UFH are recommended when fondaparinux is not available.</li> <li>• Enoxaparin should be considered as an anticoagulant for PCI in patients pretreated for PCI with subcutaneous enoxaparin.</li> <li>• Additional activated clotting time-guided intravenous boluses of UFH during PCI may be considered following initial UFH treatment.</li> <li>• Discontinuation of anticoagulation should be considered after PCI, unless otherwise indicated.</li> <li>• Crossover between UFH and LMWH is not recommended.</li> <li>• In NSTEMI patients with no prior stroke/TIA and at high ischemic risk as well as low bleeding risk receiving aspirin and clopidogrel, low-dose rivaroxaban (2.5 mg twice daily for approximately one year) may be considered after discontinuation of parenteral anticoagulation.</li> </ul> <p><u>Recommendations for combining antiplatelet agents and anticoagulants in non-ST-elevation acute coronary syndrome patients requiring chronic oral anticoagulation</u></p> <ul style="list-style-type: none"> <li>• In patients with a firm indication for oral anticoagulation (e.g., atrial fibrillation with a CHADS<sub>2</sub>-VASc score <math>\geq 2</math>, recent VTE, mechanical valve prosthesis), oral anticoagulation is recommended in addition to antiplatelet therapy.</li> <li>• An early invasive coronary angiography (within 24 hours) should be considered in moderate- to high-risk patients, irrespective of oral anticoagulant exposure, to expedite treatment allocation (medical vs PCI vs CABG) and to determine optimal antithrombotic regimen.</li> <li>• Initial dual antiplatelet therapy with aspirin plus a P2Y<sub>12</sub> inhibitor in addition to oral anticoagulation before coronary angiography is not recommended.</li> <li>• During PCI, additional parenteral anticoagulation is recommended, irrespective of the timing of the last dose of all non-vitamin K antagonist oral anticoagulants (NOACs) and if INR is <math>&lt; 2.5</math> in VKA-treated patients.</li> <li>• Uninterrupted therapeutic anticoagulation with VKA or NOACs should be considered during the periprocedural phase.</li> <li>• Periprocedural DAPT administration consisting of aspirin and clopidogrel up to one week is recommended</li> <li>• Discontinuation of antiplatelet treatment in patients treated with an oral anticoagulant is recommended after 12 months</li> <li>• Following coronary stenting, dual (oral) antiplatelet therapy (DAPT) including new P2Y<sub>12</sub> inhibitors should be considered as an alternative to triple therapy for patients with non-ST-elevation acute coronary syndromes and atrial fibrillation with a CHADS<sub>2</sub>-VASc score of 1 (in males) or 2 (in females).</li> <li>• If at low bleeding risk (HAS-BLED <math>\leq 2</math>), triple therapy with oral anticoagulant, aspirin, and clopidogrel should be considered for six months, followed by oral anticoagulant and aspirin or clopidogrel continued up to 12 months.</li> <li>• If at high bleeding risk (HAS-BLED <math>\geq 3</math>), triple therapy with oral anticoagulant, aspirin, and clopidogrel should be considered for one month, followed by oral anticoagulant and aspirin or clopidogrel continued up to 12 months irrespective of the stent type.</li> <li>• Dual therapy with oral anticoagulant and clopidogrel may be considered as an alternative to triple antithrombotic therapy in selected patients (HAS-BLED <math>\geq 3</math> and low risk of stent thrombosis).</li> <li>• The use of ticagrelor or prasugrel as part of triple therapy is not recommended.</li> <li>• In medically managed patients, one antiplatelet agent in addition to oral anticoagulant should be considered for up to one year.</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Recommendations for post-interventional and maintenance treatment</u></p> <ul style="list-style-type: none"> <li>• In patients with NSTEMI-ACS with coronary stent implantation, DAPT with a P2Y<sub>12</sub> inhibitor on top of aspirin is recommended for 12 months unless there are contraindications such as excessive risk of bleeding.</li> <li>• Adding a second anti-thrombotic agent to aspirin for extended long-term secondary prevention should be considered in patients with a moderate to high risk of ischemic events and without increased risk of major bleeding.</li> <li>• After stent implantation with high risk of bleeding, discontinuation of P2Y<sub>12</sub> inhibitor therapy after three months should be considered</li> <li>• After stent implantation in patients undergoing DAPT, stopping aspirin after three to six months should be considered, depending on balance between ischemic and bleeding risk.</li> <li>• De-escalation of P2Y<sub>12</sub> inhibitor treatment may be considered as an alternative DAPT strategy, especially for ACS patients deemed unsuitable for potent platelet inhibition.</li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure (2021)</b><sup>17</sup></p>	<p><u>Pharmacological treatments indicated in patients with (NYHA Class II-IV) heart failure with reduced ejection fraction</u></p> <ul style="list-style-type: none"> <li>• An ACE inhibitor is recommended, in addition to a <math>\beta</math>-blocker, for symptomatic patients with HFrEF to reduce the risk of HF hospitalization and death.</li> <li>• A mineralocorticoid receptor antagonist (MRA) is recommended for patients with HFrEF, who remain symptomatic despite treatment with an ACE inhibitor and a <math>\beta</math>-blocker, to reduce the risk of HF hospitalization and death.</li> <li>• Dapagliflozin or empagliflozin are recommended for patients with HFrEF to reduce the risk of HF hospitalization and death. Dapagliflozin or empagliflozin are recommended, in addition to optimal medical therapy with an ACE-I/ARNI, a <math>\beta</math>-blocker and an MRA, for patients with HFrEF regardless of diabetes status.</li> <li>• Sacubitril-valsartan is recommended as a replacement for an ACE inhibitor to further reduce the risk of HF hospitalization and death in ambulatory patients with HFrEF who remain symptomatic despite optimal treatment with an ACE inhibitor, a <math>\beta</math>-blocker, and a mineralocorticoid receptor antagonist.</li> <li>• Diuretics are recommended in order to improve symptoms and exercise capacity in patients with signs and/or symptoms of congestion.</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization or cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm despite treatment with an evidence-based dose of <math>\beta</math>-blocker (or maximum tolerated dose below that), ACE inhibitor (or ARB), and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm who are unable to tolerate or have contraindications for a <math>\beta</math>-blocker. Patients should also receive an ACE inhibitor (or ARB) and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• An ARB is recommended to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients unable to tolerate an ACE inhibitor (patients should also receive a <math>\beta</math>-blocker and mineralocorticoid receptor antagonist).</li> <li>• An ARB may be considered to reduce the risk of HF hospitalization and death in patients who are symptomatic despite treatment with a <math>\beta</math>-blocker who are unable to tolerate a mineralocorticoid receptor antagonist.</li> <li>• Vericiguat may be considered in patients in NYHA class II-IV who have had worsening HF despite treatment with an ACE-I (or ARNI), a <math>\beta</math>-blocker and an MRA to reduce the risk of CV mortality or HF hospitalization.</li> <li>• Hydralazine and isosorbide dinitrate should be considered in self-identified black patients with LVEF <math>\leq 35\%</math> or with an LVEF <math>&lt; 45\%</math> combined with a</li> </ul>

Clinical Guideline	Recommendations
	<p>dilated LV in NYHA Class III–IV despite treatment with an ACE-I a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist to reduce the risk of HF hospitalization and death.</p> <ul style="list-style-type: none"> <li>• Hydralazine and isosorbide dinitrate may be considered in symptomatic patients with HFrEF who can tolerate neither an ACE inhibitor nor an ARB (or they are contraindicated) to reduce the risk of death.</li> <li>• Digoxin is a treatment with less-certain benefits and may be considered in symptomatic patients in sinus rhythm despite treatment with an ACE inhibitor (or ARB), a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist, to reduce the risk of hospitalization (both all-cause and HF-hospitalizations).</li> </ul> <p><u>Recommendations for treatment of patients with (NYHA class II-IV) heart failure with mildly reduced ejection fraction (HFmrEF)</u></p> <ul style="list-style-type: none"> <li>• Diuretics are recommended in patients with congestion and HFmrEF in order to alleviate symptoms and signs.</li> <li>• An ACE inhibitor may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An ARB may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• A <math>\beta</math>-blocker may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An MRA may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• Sacubitril/valsartan may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> </ul> <p><u>Recommendations for treatment of patients with heart failure with preserved ejection fraction (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• It is recommended to screen patients with HFpEF for both cardiovascular and noncardiovascular comorbidities, which, if present, should be treated provided safe and effective interventions exist to improve symptoms, well-being and/or prognosis.</li> <li>• Diuretics are recommended in congested patients with HFpEF in order to alleviate symptoms and signs.</li> </ul> <p><u>Recommendations for the primary prevention of heart failure in patients with risk factors for its development</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension is recommended to prevent or delay the onset of HF and prolong life.</li> <li>• Treatment with statins is recommended in patients at high risk of CV disease or with CV disease in order to prevent or delay the onset of HF, and to prevent HF hospitalizations.</li> <li>• SGLT2 inhibitors (canagliflozin, dapagliflozin, empagliflozin, ertugliflozin, sotagliflozin) are recommended in patients with diabetes at high risk of CV disease or with CV disease in order to prevent HF hospitalizations.</li> <li>• Counselling against sedentary habit, obesity, cigarette smoking, and alcohol abuse is recommended to prevent or delay the onset of HF.</li> </ul> <p><u>Recommendations for the initial management of patients with acute heart failure – pharmacotherapy</u></p> <ul style="list-style-type: none"> <li>• Intravenous loop diuretics are recommended for all patients with acute HF admitted with signs/symptoms of fluid overload to improve symptoms. It is recommended to regularly monitor symptoms, urine output, renal function and electrolytes during use of intravenous diuretics.</li> <li>• Combination of a loop diuretic with thiazide type diuretic should be considered</li> </ul>

Clinical Guideline	Recommendations
	<p>in patients with resistant oedema who do not respond to an increase in loop diuretic doses.</p> <ul style="list-style-type: none"> <li>• In patients with acute HF and SBP &gt;110 mmHg, intravenous vasodilators may be considered as initial therapy to improve symptoms and reduce congestion.</li> <li>• Inotropic agents may be considered in patients with SBP &lt;90 mmHg and evidence of hypoperfusion who do not respond to standard treatment, including fluid challenge, to improve peripheral perfusion and maintain end-organ function.</li> <li>• Inotropic agents are not recommended routinely, due to safety concerns, unless the patient has symptomatic hypotension and evidence of hypoperfusion.</li> <li>• A vasopressor, preferably norepinephrine, may be considered in patients with cardiogenic shock to increase blood pressure and vital organ perfusion.</li> <li>• Thromboembolism prophylaxis (e.g., with LMWH) is recommended in patients not already anticoagulated and with no contraindication to anticoagulation, to reduce the risk of deep venous thrombosis and pulmonary embolism.</li> <li>• Routine use of opiates is not recommended, unless in selected patients with severe/intractable pain or anxiety.</li> </ul>

### III. Indications

The Food and Drug Administration (FDA)-approved indications for the direct vasodilators are noted in Table 3. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 3. FDA-Approved Indications for the Direct Vasodilators<sup>1-4</sup>**

Indication	Single Entity Agents		Combination Products
	Hydralazine	Minoxidil	Isosorbide Dinitrate and Hydralazine
<b>Heart Failure</b>			
Treatment of heart failure as an adjunct to standard therapy in self-identified black patients to improve survival, to prolong time to hospitalization for heart failure, and to improve patient-reported functional status			✓
<b>Hypertension</b>			
Treatment of essential hypertension	✓ *		
Treatment of hypertension		✓ †	
Treatment of severe essential hypertension	✓ ‡		

\*Tablet: Alone or as an adjunct.

†Because of the potential for serious adverse effects, minoxidil tablet is only indicated for the treatment of hypertension that is symptomatic or associated with target organ damage and is not manageable with maximum therapeutic doses of a diuretic plus two other antihypertensive drugs. At the present time use in milder degrees of hypertension is not recommended because the benefit-risk relationship has not been defined.

‡Injection: When the drug cannot be given orally or when there is an urgent need to lower blood pressure.

### IV. Pharmacokinetics

The pharmacokinetic parameters of the direct vasodilators are listed in Table 4.

**Table 4. Pharmacokinetic Parameters of the Direct Vasodilators<sup>2</sup>**

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life (hours)
<b>Single Entity Agents</b>					
Hydralazine	38 to 50	88 to 90	Liver, significant (%)	Renal (3 to 14) Feces (3 to 12)	3 to 5

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life (hours)
			not reported)		
Minoxidil	90 to 100	Insignificant (% not reported)	Liver (90)	Renal (90) Feces (3)	4.2
<b>Combination Products</b>					
Isosorbide dinitrate and hydralazine	H: 10 to 26 I: ~25	H: 88 to 90 I: 28	H: Liver, significant (% not reported) I: Liver, significant (% not reported)	H: Not reported I: Not reported	H: 3 to 5 I: 2

H=hydralazine, I=isosorbide dinitrate

## V. Drug Interactions

Significant drug interactions with the direct vasodilators are listed in Table 5.

**Table 5. Significant Drug Interactions with the Direct Vasodilators<sup>2</sup>**

Generic Name(s)	Interaction	Mechanism
Nitrates and nitrites	Phosphodiesterase type 5 inhibitors	Sildenafil may potentiate the hypotensive effects of nitrates. The use of these agents in combination is contraindicated.
Nitrates and nitrites	Avanafil	Concurrent use of avanafil and isosorbide dinitrate may result in potentiation of hypotensive effects.
Nitrates and nitrites	Riociguat	Concurrent use of riociguat and nitrates may result in increased risk of hypotension.

## VI. Adverse Drug Events

The most common adverse drug events reported with the direct vasodilators are listed in Table 6. The boxed warning for minoxidil is listed in Table 7.

**Table 6. Adverse Drug Events (%) Reported with the Direct Vasodilators<sup>1-4</sup>**

**Table 7. Boxed Warning for Minoxidil<sup>1</sup>**

<b>WARNING</b>
<p>Minoxidil may produce serious adverse effects. It can cause pericardial effusion, occasionally progressing to tamponade, and it can exacerbate angina pectoris. Reserve for hypertensive patients who do not respond adequately to maximum therapeutic doses of a diuretic and two other antihypertensive agents.</p> <p>In experimental animals, minoxidil caused several kinds of myocardial lesions and other adverse cardiac effects.</p> <p>Administer under close supervision, usually concomitantly with a <math>\beta</math>-adrenergic blocking agent, to prevent tachycardia and increased myocardial workload. Usually, it must be given with a diuretic, frequently one acting in the ascending limb of the loop of Henle to prevent serious fluid accumulation. When first administering minoxidil, hospitalize and monitor patients with malignant hypertension and those already receiving guanethidine to avoid too rapid or large orthostatic decreases in blood pressure.</p>

## VII. Dosing and Administration

The usual dosing regimens for the direct vasodilators are listed in Table 8.

**Table 8. Usual Dosing Regimens for the Direct Vasodilators<sup>1-4</sup>**

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
<b>Single Entity Agents</b>			
Hydralazine	<u>Essential hypertension:</u> Injection, tablet: initial, 10 mg four times daily for the first two to four days, followed by 25 mg four times daily for the balance of the first week, then for the second and subsequent weeks, increase dosage to 50 mg four times daily; maintenance, adjust dosage to the lowest effective levels	<u>Essential hypertension:</u> Safety and effectiveness in pediatric patients have not been established in controlled clinical trials, although there is experience with the use of hydralazine in pediatric patients.  Injection, tablet: initial, 0.75 mg/kg/day administered in four divided doses; maintenance, dosage may be increased gradually over the next three to four weeks; maximum, 7.5 mg/kg or 200 mg/day	Injection: 20 mg/mL  Tablet: 10 mg 25 mg 50 mg 100 mg
Minoxidil	<u>Hypertension:</u> Tablet: initial, 5 mg/day and increase gradually every three days; maintenance, 10 to 40 mg daily in single or divided doses; maximum, 100 mg/day	<u>Hypertension:</u> Tablet: initial, 0.2 mg/kg/day; maintenance, 0.25 to 1 mg/kg/day; maximum, 50 mg/day	Tablet: 2.5 mg 10 mg
<b>Combination Products</b>			
Isosorbide dinitrate and hydralazine	<u>Heart failure:</u> Tablet: initial, 20-37.5 mg three times daily; maximum, 40-75 mg (two tablets) three times daily	The safety and effectiveness have not been established in children.	Tablet: 20-37.5 mg

## VIII. Effectiveness

Clinical studies evaluating the safety and efficacy of the direct vasodilators are summarized in Table 9.

**Table 9. Comparative Clinical Trials with the Direct Vasodilators**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<b>Heart Failure</b>				
Unverferth et al. <sup>18</sup> (1983)  Hydralazine 225 mg/day  vs  ISDN 160 mg/day  vs  hydralazine and ISDN (individual agents)  vs  placebo	DB, PC, RCT  Patients with idiopathic dilated cardiomyopathy were evaluated to determine the hemodynamic and morphologic effects of vasodilator therapy	N=49  3 months	Primary: Echocardiographic percent change of left ventricular diameter, the systolic time intervals ratio of PEP/LVET, the pulmonary capillary wedge pressure, mean pulmonary artery pressure, pulmonary vascular resistance, cardiac index, and SVR  Secondary: Not reported	Primary: For the percent change in left ventricular diameter and PEP/LVET, a significant improvement with hydralazine and combination therapy (P<0.05) was seen compared to ISDN alone or placebo.  Significant decrease with ISDN and combination therapy vs placebo or hydralazine alone (P<0.05) was seen for pulmonary capillary wedge pressure, mean pulmonary artery pressure, and the pulmonary vascular resistance.  Hydralazine resulted in a decrease in SVR and increase in cardiac index from 2.5±0.4 to 3.1±0.4 L/min/m <sup>2</sup> vs placebo or ISDN alone (P<0.05).  Combination therapy resulted in a decrease in SVR and cardiac index increased from 2.3±0.4 to 3.1±0.4 L/min/m <sup>2</sup> (P<0.01).  There was no improvement in SVR or cardiac index with ISDN alone or with placebo.  Myocardial cell diameter decreased from 25.4±3.1 microns at baseline to 23.1±3.8 microns with hydralazine (P<0.05). Combination therapy decreased its cell diameter from 23.9±3.7 to 22.2±2.2 microns (P<0.05).  There was no change in the myocardial cell diameter seen in patients treated with ISDN alone or with placebo.  Secondary: Not reported
Taylor <sup>19</sup> (2005) A-HeFT	DB, MC, PC, RCT  African American	N=1,050  6 to 18 months	Primary: Composite score (all-cause	Primary: Mortality in the fixed-dose ISDN and hydralazine group was 6.2% compared to 10.2% in the placebo group (P=0.02).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
ISDN and hydralazine 60-112.5 mg/day in 3 divided doses, titrated up to ISDN and hydralazine 120-225 mg/day in 3 divided doses (fixed-dose combination product)  vs  placebo	patients with moderate-to-severe symptomatic heart failure, classified NYHA class III to IV heart failure with dilated ventricles and low ejection fractions		mortality, first hospitalization for heart failure, and quality of life at 6 months as measured by the Minnesota Living with Heart Failure questionnaire)  Secondary: Not reported	Survival was increased by 43% in the active treatment arm (HR, 0.57; P=0.02).  The composite score and all individual components of the composite score were significantly and positively impacted by treatment with ISDN and hydralazine (primary composite score P=0.01, death from any cause P=0.02, first hospitalization for heart failure P=0.001, change in quality of life score at 6 months P=0.02).  The study was prematurely terminated in as a result of the significantly improved survival in the ISDN and hydralazine group.  Secondary: Not reported
Taylor et al. <sup>20</sup> (2004) A-HeFT  ISDN and hydralazine 20-37.5 mg TID, increased to ISDN and hydralazine 40-75 mg TID (fixed-dose combination product)  vs  placebo	DB, MC, PC, RCT  Patients ≥18 years of age, self-identified as of African descent, with NYHA class III or IV heart failure on standard therapy for ≥3 months and evidence of left ventricular dysfunction within the prior 6 months	N=1,050  18 months (mean duration of follow-up was 10 months)	Primary: A composite score made up of weighted values for death from any cause, a first hospitalization for heart failure, and quality of life changes  Secondary: Individual components of the primary composite score	Primary: From a range of possible scores of -6 to 2 for the composite endpoint, patients in the active treatment group achieved a significantly better score of -0.1±1.9 compared -0.5±2.0 in the placebo group (P=0.01).  Secondary: There was a significantly higher mortality rate in the placebo group compared to the ISDN and hydralazine group (6.2 vs 10.2%; P=0.02). Survival was increased by 43% in the active treatment group (HR, 0.57; P=0.02). This led to the early termination of the trial.  Compared to the placebo group, the rate of first hospitalization for heart failure was significantly reduced in the ISDN and hydralazine group (16.4 vs 24.4%; P=0.001).  There was a significant improvement in quality of life scores found with the ISDN and hydralazine group when compared to the placebo group (-5.6±20.6 vs -2.7±21.2; P=0.02).
Taylor et al. <sup>21</sup> (2007) A-HeFT	Post-hoc analysis of A-HeFT	N=1,050  Mean duration	Primary: Cause specific mortality, event	Primary: Cardiovascular deaths were significantly reduced in the treatment group compared to the placebo group (5.0 vs 8.5%; P=0.027). Pump failure

Yancy et al. <sup>23</sup> (2007) A-HeFT  ISDN and hydralazine 20-37.5 mg TID, increased to ISDN and hydralazine 40-75 mg TID (fixed-dose combination product)  vs  placebo	ES, OL  Patients previously enrolled in A-HeFT with NYHA class I to IV heart failure symptoms while receiving background therapy and satisfying the A-HeFT inclusion criteria	N=158  12 months or until ISDN and hydralazine approved by the FDA	Primary: Compliance with study drug, safety, tolerability  Secondary: Change in NYHA association class, death, hospitalization for heart failure	Primary: Compliance in the treatment group averaged 87±25%, with no significant difference when compared to the placebo group.  There were no significant differences in adverse events between the groups.  Secondary: No significant difference was seen in hospitalizations from heart failure according to randomization.  The greatest improvement in heart failure symptoms occurred in NYHA class III (at baseline) compared to other classes (P<0.001).  Overall most patients were unchanged with 24% showing improved NYHA class and 9% showing a worsening.
Cohn et al. <sup>24</sup> (1986) V-HeFT I  Hydralazine 300 mg/day plus ISDN 160 mg/day (individual agents, concurrent therapy)  vs  prazosin 20 mg/day  vs  placebo	AC, DB, PC, RCT  Men with impaired cardiac function and reduced exercise tolerance on digoxin and a diuretic	N=642  3 years	Primary: Mortality  Secondary: Effect on left ventricular function	Primary: There was a 34% risk reduction in mortality by two years in the hydralazine plus ISDN group compared to placebo (P<0.028).  Cumulative mortality rates of 25.6 and 36.2% were observed in the hydralazine plus ISDN group at 2 and 3 years respectively, compared to 34.3 and 46.9% in the placebo group. The results found in the prazosin group were similar to placebo.  Secondary: A significant increase in the left ventricular ejection fraction was reported at eight weeks and one year in the hydralazine plus ISDN treatment group, but not in either the prazosin or placebo groups.

## IX. Cost

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of '\$' signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 10. Relative Cost of the Direct Vasodilators**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost
<b>Single Entity Agents</b>				
Hydralazine	injection, tablet	N/A	N/A	\$
Minoxidil	tablet	N/A	N/A	\$
<b>Combination Products</b>				
Isosorbide dinitrate and hydralazine	tablet	BiDil®	\$\$\$\$\$	N/A

\*Generic is available in at least one dosage form or strength.

N/A=not available

## X. Conclusions

Hydralazine and minoxidil are approved for the treatment of hypertension, and both agents are available in a generic formulation.<sup>1,2,4</sup> There are several national and international organizations that have published guidelines on the treatment of hypertension. Most of the guidelines do not provide recommendations on the use of the oral direct vasodilators.<sup>5-11</sup> Thiazide-type diuretics are frequently recommended as initial therapy in patients with uncomplicated hypertension. According to the National Heart, Lung, and Blood Institute's Eighth Report of The Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 8), thiazide-type diuretics should be utilized first-line for most patients with hypertension, either alone or in combination with another antihypertensive from a different medication class (e.g., ACE inhibitors, ARBs, β-

blockers, calcium channel blockers).<sup>5</sup> Several guidelines consistently recommend that the selection of an antihypertensive agent be based on compelling indications for use.<sup>5-11</sup> Most patients will require more than one antihypertensive medication to achieve blood pressure goals.<sup>5-11</sup> Clinical trials have demonstrated that hydralazine and minoxidil are effective for the treatment of hypertension when added to existing therapy in patients whose blood pressure is inadequately controlled. There are limited head-to-head trials comparing the direct vasodilators.<sup>27-31</sup> These agents are associated with several potentially severe adverse effects, which limits their use in the treatment of hypertension.<sup>1,2</sup>

Hydralazine and isosorbide dinitrate (administered as single entity products) have been used off-label to treat heart failure for many years. The combination of these agents has been shown to reduce mortality compared to placebo in patients receiving standard therapy with digoxin and diuretics.<sup>24</sup> However, when hydralazine and isosorbide dinitrate were directly compared to an ACE inhibitor, mortality was significantly lower in the ACE inhibitor group.<sup>25</sup> Treatment guidelines for the management of heart failure currently recommend the use of hydralazine and an oral nitrate in patients who do not tolerate an ACE inhibitor or ARB.<sup>13-17</sup> The fixed-dose combination of isosorbide dinitrate and hydralazine is FDA-approved for the treatment of heart failure as an adjunct to standard therapy in self-identified black patients.<sup>3</sup> In the A-HeFT trial, the use of this combination product improved mortality, prolonged time to hospitalization for heart failure, and improved functional status compared to placebo. The patients in this trial were also receiving standard heart failure therapy prior to enrollment (ACE inhibitors, angiotensin II receptor antagonists,  $\beta$ -blockers, diuretics, digoxin, spironolactone).<sup>3,19-22</sup> The Heart Failure Society of America and the American College of Cardiology Foundation/American Heart Association recommend the use of the fixed-dose combination of isosorbide dinitrate and hydralazine in African American patients with NYHA functional class III or IV heart failure who are on a standard regimen including an ACE inhibitor (or ARB) and a  $\beta$ -blocker.<sup>14</sup> Both hydralazine and isosorbide dinitrate are available generically; however, generic hydralazine is not available in a strength equivalent to the fixed-dose combination product.<sup>1-4</sup>

Therefore, all brand direct vasodilators within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use. The fixed-dose combination of isosorbide dinitrate and hydralazine (BiDil<sup>®</sup>) should be available through the medical justification portion of the prior authorization process as an adjunct to standard heart failure therapy in self-identified black patients.

## **XI. Recommendations**

No brand direct vasodilator is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

**Alabama Medicaid Agency  
Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Peripheral Adrenergic Inhibitors  
AHFS Class 240832  
May 4, 2022**

**I. Overview**

In 2016, reserpine was discontinued. Currently, there are no drugs classified by AHFS as peripheral adrenergic inhibitors.

**II. Conclusions**

There are no drugs available in the peripheral adrenergic inhibitor class (AHFS Class 240832).

**III. Recommendations**

No brand peripheral adrenergic inhibitor is recommended for preferred status. Alabama Medicaid should continue to include AHFS Class 240832 in the PDL screening process. If new outpatient peripheral adrenergic inhibitors are added, it is recommended that this class be re-reviewed at that time.

**Alabama Medicaid Agency  
Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Hypotensive Agents, Miscellaneous  
AHFS Class 240892  
May 4, 2022**

**I. Overview**

Mecamylamine was one of the first oral antihypertensive agents, introduced in the mid-1950s under the trade name Inversine<sup>®</sup>. It was withdrawn from the market in 2009 due to increased competition of antihypertensive drugs and decreasing use of the agent. In March 2013, mecamylamine was issued FDA approval and re-entered the market under the name of Vecamyl<sup>®</sup>.<sup>1,2</sup> Mecamylamine, a ganglionic blocker and secondary amine, inhibits acetylcholine at the autonomic ganglia. This causes blood vessel dilation and an increase in peripheral blood flow resulting in a decrease in blood pressure. Additionally, it blocks central nicotinic cholinergic receptors. Mecamylamine use has diminished due to its ganglionic side effects at antihypertensive doses.<sup>1,3,4</sup>

The miscellaneous hypotensive agents that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. This class was last reviewed in February 2020.

**Table 1. Miscellaneous Hypotensive Agents Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
Mecamylamine	tablet	Vecamyl <sup>®</sup>	none

PDL=Preferred Drug List

**II. Evidence-Based Medicine and Current Treatment Guidelines**

The miscellaneous hypotensive agents are not included in the treatment guidelines and there are no specific recommendations for this drug.

**III. Indications**

Food and Drug Administration (FDA)-approved indications for the miscellaneous hypotensive agents are listed in Table 2. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 2. FDA-Approved Indications for the Miscellaneous Hypotensive Agents<sup>3</sup>**

Indication	Mecamylamine
Management of moderately severe to severe essential hypertension and in uncomplicated cases of malignant hypertension.	✓

**IV. Pharmacokinetics**

The pharmacokinetic parameters for miscellaneous hypotensive agents are summarized in Table 3.

**Table 3. Pharmacokinetic Parameters of the Miscellaneous Hypotensive Agents<sup>4</sup>**

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Elimination (%)	Half-life (hours)	Active Metabolites
Mecamylamine	Not reported*	Not reported	Renal (100)	24	Not reported

\*It is noted that mecamylamine is readily absorbed from the gastrointestinal tract

## V. Drug Interactions

There are no reported drug interactions of major or moderate significance with the miscellaneous hypotensive agent, mecamylamine, although the package insert states that patients receiving antibiotics and sulfonamides generally should not be treated with ganglion blockers.<sup>3,5</sup> Additionally, the action of mecamylamine may be amplified by anesthesia, other antihypertensive agents, and alcohol. The mechanism of these interactions and specific drug agents are not specified.<sup>3</sup>

## VI. Adverse Drug Events

The most common adverse reactions reported with the miscellaneous hypotensive agents are noted in Table 4.

**Table 4. Adverse Events (%) Reported with the Miscellaneous Hypotensive Agents<sup>3</sup>**

Adverse Events	Mecamylamine
<b>Cardiovascular</b>	
Orthostatic dizziness	✓
Postural hypotension	✓
Syncope	✓
<b>Central Nervous System</b>	
Choreiform movements	✓
Convulsions	✓
Mental aberrations	✓
Paresthesias	✓
Tremor	✓
<b>Gastrointestinal</b>	
Anorexia	✓
Constipation	✓
Dry mouth	✓
Glossitis	✓
Ileus	✓
Nausea	✓
Vomiting	✓
<b>Respiratory</b>

Urinary retention	✓
<b>Other</b>	
Blurred vision	✓
Dilated pupils	✓
Fatigue	✓
Sedation	✓
Weakness	✓

## VII. Dosing and Administration

The usual dosing regimens for the miscellaneous hypotensive agents are summarized in Table 5.

**Table 5. Usual Dosing for the Miscellaneous Hypotensive Agents<sup>3</sup>**

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
-----------------	------------------	----------------------	--------------

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
Mecamylamine	<p><u>Management of moderately severe to severe essential hypertension and in uncomplicated cases of malignant hypertension:</u>                      Tablet: initial, 2.5 mg twice daily (titrate in increments of 2.5 mg with at least two day intervals); average, 25 mg daily, in three divided doses (some patients may respond to as little as 2.5 mg daily; however, some patients may require two to four doses or greater in severe cases when consistent control is difficult to achieve); partial tolerance may develop requiring daily dosage increases</p>	Safety and effectiveness have not been established.	Tablet: 2.5 mg

### VIII. Effectiveness

A thorough literature search from 1966 to the present failed to retrieve any clinical studies evaluating the safety and effectiveness of mecamylamine for the treatment of hypertension. The initial clinical trials were conducted in the 1950s. These trials established the drug’s efficacy and side effect profile in patients with severe hypertension.<sup>1</sup>

#### Additional Evidence

##### Dose Simplification

A search of Medline and PubMed did not reveal data pertinent to this topic.

##### Stable Therapy

A search of Medline and PubMed did not reveal data pertinent to this topic.

##### Impact on Physician Visits

A search of Medline and PubMed did not reveal data pertinent to this topic.

### IX. Cost

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of ‘\$’ signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 10. Relative Cost of the Miscellaneous Hypotensive Agents**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost
Mecamylamine	tablet	Vecamyl <sup>®</sup>	\$\$\$\$\$	N/A

\*Generic is available in at least one dosage form or strength.  
 N/A=not available

**X. Conclusions**

Although the clinical literature reports that mecamylamine is effective for the management of moderate-to-severe hypertension, its clinical utility is minimal due to its adverse events profile and the availability of newer and more effective agents. Current hypertension treatment guidelines do not mention mecamylamine as a first-line or alternative agent for the treatment of hypertension. Therefore, all brand miscellaneous hypotensive agents within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

**XI. Recommendations**

No brand miscellaneous hypotensive agent is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine cost effective products and possibly designate one or more preferred brands.

**Alabama Medicaid Agency  
Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Alpha-Adrenergic Blocking Agents  
AHFS Class 242000  
May 4, 2022**

**I. Overview**

The alpha-adrenergic blocking agents are approved for the treatment of benign prostatic hyperplasia (BPH) and hypertension.<sup>1-6</sup> However, the use of these agents for the treatment of hypertension is somewhat limited due to adverse events. They can cause postural hypotension, reducing the standing systolic blood pressure by more than 10 mm Hg. Syncope with sudden loss of consciousness can also occur, especially with the first few doses, rapid dose increases, or the addition of another antihypertensive agent to the treatment regimen. Unlike diuretics and  $\beta$ -adrenergic blocking agents,  $\alpha$ -adrenergic blocking agents do not adversely affect lipids. They have been shown to reduce total cholesterol by 3 to 5% and triglycerides by 3 to 4%, as well as increase high-density lipoprotein cholesterol.<sup>7</sup> The  $\alpha$ -adrenergic blocking agents are more commonly used to relieve symptoms of BPH, which is characterized by an enlargement of the prostate gland. BPH is associated with lower urinary tract symptoms, such as frequent daytime urination, nocturia, a sensation of incomplete bladder emptying, and a hesitant, weak, or intermittent urinary stream.<sup>8,9</sup>

The  $\alpha$ -adrenergic blocking agents competitively inhibit postsynaptic  $\alpha_1$ -adrenergic receptors, which are classified into three subtypes:  $\alpha_{1A}$ ,  $\alpha_{1B}$ , and  $\alpha_{1D}$ .<sup>10-13</sup> These receptors are located in the smooth muscle cell membrane of the peripheral blood vessels, as well as in various nonvascular smooth muscle and non-muscular tissues.<sup>11-15</sup> The  $\alpha$ -adrenergic blocking agents lower blood pressure by acting peripherally to dilate the blood vessels. They also cause rapid relaxation of smooth muscle in the bladder neck, prostate capsule, and prostatic urethra.<sup>14,16</sup>

The  $\alpha$ -adrenergic blocking agents that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. All of the products are available in a generic formulation. This class was last reviewed in February 2020.

**Table 1. Alpha-Adrenergic Blocking Agents Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
Doxazosin	extended-release tablet, tablet	Cardura <sup>®*</sup> , Cardura XL <sup>®</sup>	doxazosin
Prazosin	capsule	Minipress <sup>®*</sup>	prazosin
Terazosin	capsule	N/A	terazosin

\*Generic is available in at least one dosage form or strength.

PDL=Preferred Drug List

N/A=Not available

**II. Evidence-Based Medicine and Current Treatment Guidelines**

Current treatment guidelines that incorporate the use of the  $\alpha$ -adrenergic blocking agents are summarized in Table 2.

**Table 2. Treatment Guidelines Using the Alpha-Adrenergic Blocking Agents**

Clinical Guideline	Recommendations
Eighth Joint National Committee (JNC 8): <b>2014 Evidence-based Guideline for the Management of High Blood Pressure in Adults (2014)</b> <sup>17</sup>	<ul style="list-style-type: none"> <li>Pharmacologic treatment should be initiated in patients <math>\geq 60</math> years of age to lower blood pressure at systolic blood pressure <math>\geq 150</math> mm Hg or diastolic blood pressure <math>\geq 90</math> mm Hg and to a goal systolic blood pressure <math>&lt; 150</math> mm Hg and goal diastolic blood pressure <math>&lt; 90</math> mm Hg. Adjustment of treatment is not necessary if treatment results in lower blood pressure and treatment is well tolerated and without adverse effects on health or quality of life.</li> <li>In patients <math>&lt; 60</math> years of age, pharmacologic treatment should be initiated to lower blood pressure at diastolic blood pressure <math>\geq 90</math> mm Hg to a goal diastolic blood pressure <math>&lt; 90</math> mm Hg.</li> <li>In patients <math>&lt; 60</math> years of age, pharmacologic treatment should be initiated to</li> </ul>

Clinical Guideline	Recommendations
	<p>lower blood pressure at systolic blood pressure <math>\geq 150</math> mm Hg to a goal diastolic blood pressure <math>&lt; 140</math> mm Hg.</p> <ul style="list-style-type: none"> <li>• For patients <math>\geq 18</math> years of age with chronic kidney disease or diabetes, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure <math>\geq 140</math> mm Hg or diastolic blood pressure <math>\geq 90</math> mm Hg and to a goal systolic blood pressure <math>&lt; 140</math> mm Hg and goal diastolic blood pressure <math>&lt; 90</math> mm Hg.</li> <li>• Initial antihypertensive treatment for the general nonblack population, including those with diabetes, should include thiazide-type diuretic, calcium channel blocker (CCB), ACE inhibitor, or ARB.</li> <li>• Initial antihypertensive treatment for the general black population, including those with diabetes, should include thiazide-type diuretic or CCB.</li> <li>• For patients <math>\geq 18</math> years of age with chronic kidney disease regardless of race or diabetes status, initial (or add-on) treatment should include an ACE inhibitor or ARB to improve kidney outcomes.</li> <li>• The main goal of antihypertensive treatment is to attain and maintain goal blood pressure.</li> <li>• If goal blood pressure is not attained within a month of treatment, the dose of the initial drug should be increased or second drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• If goal is not achieved with two drugs, a third drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• An ACE inhibitor and ARB should not be used together.</li> <li>• Antihypertensive classes can be used if the patient is unable to achieve goal blood pressure with three agents or had a contraindication to a preferred class.</li> <li>• If blood pressure is not able to be achieved or in complicated patients, referral to a hypertension specialist may be indicated.</li> </ul>
<p>International Society of Hypertension: <b>Global Hypertension Practice Guidelines (2020)</b><sup>18</sup></p>	<p><u>Lifestyle modifications</u></p> <ul style="list-style-type: none"> <li>• Lifestyle modification is the first line of antihypertensive treatment.</li> <li>• Salt reduction: Reduce salt added when preparing foods, and at the table. Avoid or limit consumption of high salt foods such as soy sauce, fast foods and processed food including breads and cereals high in salt.</li> <li>• Healthy diet: Eating a diet that is rich in whole grains, fruits, vegetables, polyunsaturated fats and dairy products and reducing food high in sugar, saturated fat and trans fats, such as the DASH diet.</li> <li>• Healthy drinks: Moderate consumption of coffee, green and black tea. Other beverages that can be beneficial include karkadé (hibiscus) tea, pomegranate juice, beetroot juice and cocoa.</li> <li>• Moderation of alcohol consumption: The recommended daily limit for alcohol consumptions is 2 standard drinks for men and 1.5 for women (10 g alcohol/standard drink). Avoid binge drinking.</li> <li>• Weight reduction: Body weight control is indicated to avoid obesity. Particularly abdominal obesity should be managed. Ethnic-specific cut-offs for BMI and waist circumference should be used. Alternatively, a waist-to-height ratio <math>&lt; 0.5</math> is recommended for all populations.</li> <li>• Smoking cessation: Smoking is a major risk factor for cardiovascular disease (CVD), COPD and cancer. Smoking cessation and referral to smoking cessation programs are advised.</li> <li>• Regular physical activity: Studies suggest that regular aerobic and resistance exercise may be beneficial for both the prevention and treatment of hypertension. Moderate intensity aerobic exercise (walking, jogging, cycling, yoga, or swimming) for 30 minutes on five to seven days per week. Strength training also can help reduce blood pressure. Performance of resistance/strength exercises on two to three days per week.</li> <li>• Reduce stress and induce mindfulness: Stress should be reduced and</li> </ul>

Clinical Guideline	Recommendations
	<p>mindfulness or meditation introduced into the daily routine.</p> <ul style="list-style-type: none"> <li>• Reduce exposure to air pollution and cold temperature: Evidence from studies support a negative effect of air pollution on blood pressure in the long-term.</li> </ul> <p><u>Pharmacological Treatment</u></p> <ul style="list-style-type: none"> <li>• Ideal characteristics of drug treatment               <ul style="list-style-type: none"> <li>○ Treatments should be evidence-based in relation to morbidity/mortality prevention.</li> <li>○ Use a once-daily regimen which provides 24-hour blood pressure control.</li> <li>○ Treatment should be affordable and/or cost-effective relative to other agents.</li> <li>○ Treatments should be well-tolerated.</li> <li>○ Evidence of benefits of use of the medication in populations to which it is to be applied.</li> </ul> </li> <li>• General scheme for drug treatment               <ul style="list-style-type: none"> <li>○ Lifestyle modification is the first line of antihypertensive treatment.</li> <li>○ Grade 1 hypertension (BP 140 to 159/ 90 to 99): Immediate drug treatment in high-risk patients or those with CVD, chronic kidney disease (CKD), diabetes mellitus (DM), or hypertension-mediated organ damage (HMOD). Drug treatment after three to six months of lifestyle intervention if BP still not controlled in low to moderate risk patients.</li> <li>○ Grade 2 hypertension (BP <math>\geq</math>160/100): Immediate drug treatment in all patients.</li> </ul> </li> <li>• Core drug-treatment strategy               <ul style="list-style-type: none"> <li>○ Step 1: Dual low-dose combination (ACE inhibitor or ARB plus dihydropyridine-calcium channel blockers (DHP-CCB)); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance; consider ACE/ARB plus DHP-CCB or DHP-CCB plus thiazide-like diuretics in black patients.</li> <li>○ Step 2: Dual full-dose combination (ACE inhibitor or ARB plus DHP-CCB); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance.</li> <li>○ Step 3: Triple combination (ACE/ARB plus DHP-CCB plus thiazide-like diuretic).</li> <li>○ Step 4, resistant hypertension: triple combination plus spironolactone or other drug, alternatives include amiloride, doxazosin, eplerenone, clonidine, or <math>\beta</math>-blocker. Caution with spironolactone or other potassium sparing diuretics when estimated GFR <math>&lt;</math>45 mL/min/1.73m<sup>2</sup> or K<sup>+</sup> <math>&gt;</math>4.5 mmol/L.</li> <li>○ Consider <math>\beta</math>-blockers at any treatment step when there is a specific indications for their use, e.g., heart failure, angina, post-MI, atrial fibrillation, or younger women planning pregnancy or pregnant.</li> </ul> </li> </ul>
<p><b>Hypertension Canada: 2020 Guidelines for the Prevention, Diagnosis, Risk Assessment, and Treatment of Hypertension in Adults and Children</b></p>	<p><u>Indications for drug therapy for adults with hypertension without compelling indications for specific agents</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive therapy should be prescribed for average diastolic blood pressure (DBP) measurements of <math>\geq</math>100 mmHg or average systolic blood pressure (SBP) measurements of <math>\geq</math>160 mmHg in patients without macrovascular target organ damage or other cardiovascular risk factors.</li> <li>• Antihypertensive therapy should be strongly considered for average DPB readings <math>\geq</math>90 mmHg or for average SBP readings <math>\geq</math>140 mmHg in the presence</li> </ul>

Clinical Guideline	Recommendations
(2020) <sup>19</sup>	<p>of macrovascular target organ damage or other independent cardiovascular risk factors.</p> <ul style="list-style-type: none"> <li>• For high-risk patients, aged 50 years or older, with SBP levels <math>\geq 130</math> mmHg, intensive management to target a SBP <math>&lt; 120</math> mmHg should be considered. Patient selection for intensive management is recommended and caution should be taken in certain high-risk groups.</li> </ul> <p><u>Indications for drug therapy for adults with diastolic and with or without systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be with either monotherapy or single pill combination (SPC). <ul style="list-style-type: none"> <li>○ Recommended monotherapy choices are: <ul style="list-style-type: none"> <li>▪ A thiazide/thiazide-like diuretic, with longer-acting diuretics preferred;</li> <li>▪ A <math>\beta</math>-blocker (in patients <math>&lt; 60</math> years of age);</li> <li>▪ An angiotensin-converting enzyme (ACE) inhibitor (in nonblack patients);</li> <li>▪ An angiotensin receptor blocker (ARB); or</li> <li>▪ A long-acting calcium channel blocker (CCB).</li> </ul> </li> <li>○ Recommended SPC choices are those in which an ACE inhibitor is combined with a CCB, ARB with a CCB, or ACE inhibitor or ARB with a diuretic.</li> <li>○ Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> </ul> </li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line choices. Useful choices include a thiazide/thiazide-like diuretic or CCB with either: ACE inhibitor, ARB, or <math>\beta</math>-blocker. Caution should be exercised in combining a nondihydropyridine CCB and a <math>\beta</math>-blocker. The combination of an ACE inhibitor and an ARB is not recommended.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other antihypertensive drugs may be added.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated hypertension; <math>\beta</math>-blockers are not recommended as first-line therapy for uncomplicated hypertension in patients <math>\geq 60</math> years of age; and ACE inhibitors are not recommended as first-line therapy for uncomplicated hypertension in black patients. However, these agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Indications for drug therapy for adults with isolated systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be single-agent therapy with a thiazide/thiazide-like diuretic, a long-acting dihydropyridine CCB, or an ARB. If there are adverse effects, another drug from this group should be substituted. Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line options.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other classes of drugs (such as <math>\alpha</math>-blockers, ACE inhibitors, centrally acting agents, or nondihydropyridine CCBs) may be combined or substituted.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated isolated systolic hypertension; and <math>\beta</math>-blockers are not recommended as first-line therapy for isolated systolic hypertension in patients <math>\geq 60</math> years of age. However, both</li> </ul>

Clinical Guideline	Recommendations
	<p>agents may be used in patients with certain comorbid conditions or in combination therapy.</p> <p><u>Guidelines for hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• For most hypertensive patients with CAD, an ACE inhibitor or ARB is recommended.</li> <li>• For hypertensive patients with CAD, but without coexisting systolic heart failure, the combination of an ACE inhibitor and ARB is not recommended.</li> <li>• For high-risk hypertensive patients, when combination therapy is being used, choices should be individualized. The combination of an ACE inhibitor and a dihydropyridine CCB is preferable to an ACE inhibitor and a thiazide/thiazide-like diuretic in selected patients.</li> <li>• For patients with stable angina pectoris but without previous heart failure, myocardial infarction, or coronary artery bypass surgery, either a <math>\beta</math>-blocker or CCB can be used as initial therapy.</li> <li>• Short-acting nifedipine should not be used.</li> <li>• When decreasing SBP to target levels in patients with established CAD (especially if isolated systolic hypertension is present), be cautious when the DBP is <math>\leq 60</math> mmHg because of concerns that myocardial ischemia might be exacerbated, especially in patients with left ventricular hypertrophy (LVH).</li> </ul> <p><u>Guidelines for patients with hypertension who have had a recent myocardial infarction</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should include a <math>\beta</math>-blocker as well as an ACE inhibitor.</li> <li>• An ARB can be used if the patient is intolerant of an ACE inhibitor.</li> <li>• CCBs may be used in patients after myocardial infarction when <math>\beta</math>-blockers are contraindicated or not effective. Nondihydropyridine CCBs should not be used when there is heart failure, evidenced by pulmonary congestion on examination or radiography.</li> </ul> <p><u>Treatment of hypertension in association with heart failure</u></p> <ul style="list-style-type: none"> <li>• In patients with systolic dysfunction (ejection fraction <math>&lt;40\%</math>), ACE inhibitors and <math>\beta</math>-blockers are recommended for initial therapy. Aldosterone antagonists (mineralocorticoid receptor antagonists) may be combined in treatment for patients with a recent cardiovascular hospitalization, acute myocardial infarction, elevated B-type natriuretic peptide or N-terminal pro-B-type natriuretic peptide level, or New York Heart Association (NYHA) Class II-IV symptoms. Careful monitoring for hyperkalemia is recommended when combining an aldosterone antagonist with ACE inhibitor or ARB treatment. Other diuretics are recommended as additional therapy if needed. Beyond considerations of BP control, doses of ACE inhibitors or ARBs should be titrated to those reported to be effective in trials unless adverse effects become manifest.</li> <li>• An ARB is recommended if ACE inhibitors are not tolerated.</li> <li>• A combination of hydralazine and isosorbide dinitrate is recommended if ACE inhibitors and ARBs are contraindicated or not tolerated.</li> <li>• For hypertensive patients whose BP is not controlled, an ARB may be combined with an ACE inhibitor and other antihypertensive drug treatment. Careful monitoring should be used if combining an ACE inhibitor and an ARB because of potential adverse effects such as hypotension, hyperkalemia, and worsening renal function. Additional therapies may also include dihydropyridine CCBs.</li> <li>• An angiotensin receptor-neprilysin inhibitor (ARNI) should be used in place of an ACE inhibitor or ARB for patients with HFrEF (<math>&lt;40\%</math>) who remain symptomatic despite treatment with appropriate dose of guideline directed HF therapy. Eligible patients must have a serum potassium <math>&lt;5.2</math> mmol/L, an eGFR</li> </ul>

Clinical Guideline	Recommendations
	<p>≤30 mL/min/1.73m<sup>2</sup> and close surveillance of serum potassium and creatinine.</p>
	<p><u>Treatment of hypertension in association with stroke</u></p>
	<ul style="list-style-type: none"> <li>• BP management in acute ischemic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> <li>• BP management after acute ischemic stroke <ul style="list-style-type: none"> <li>○ Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack.</li> <li>○ After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently &lt;140/90 mmHg.</li> <li>○ Treatment with an ACE inhibitor and thiazide/thiazide-like diuretic combination is preferred.</li> <li>○ For patients with stroke, the combination of an ACE inhibitor and ARB is not recommended.</li> </ul> </li> <li>• BP management in hemorrhagic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> </ul>
	<p><u>Treatment of hypertension in association with LVH</u></p>
	<ul style="list-style-type: none"> <li>• Hypertensive patients with LVH should be treated with antihypertensive therapy to decrease the rate of subsequent cardiovascular events.</li> <li>• The choice of initial therapy can be influenced by the presence of LVH. Initial therapy can be drug treatment using ACE inhibitors, ARBs, long-acting CCBs, or thiazide/thiazide-like diuretics. Direct arterial vasodilators such as hydralazine or minoxidil should not be used.</li> </ul>
	<p><u>Treatment of hypertension in association with nondiabetic chronic kidney disease</u></p>
	<ul style="list-style-type: none"> <li>• Individualize BP targets in patients with chronic kidney disease. Consider intensive targets (SBP &lt;120 mmHg) in appropriate patients.</li> <li>• For patients with hypertension and proteinuric chronic kidney disease (urinary protein &gt;150 mg per 24 hours or albumin to creatinine ratio &gt;30 mg/mmol), initial therapy should be an ACE inhibitor or an ARB if there is intolerance to ACE inhibitors.</li> <li>• In most cases, combination therapy with other antihypertensive agents might be needed to reach target BP levels.</li> <li>• The combination of an ACE inhibitor and ARB is not recommended for patients with nonproteinuric chronic kidney disease.</li> </ul>
	<p><u>Treatment of hypertension in association with renovascular disease</u></p>
	<ul style="list-style-type: none"> <li>• Patients with hypertension attributable to atherosclerotic renal artery stenosis should be primarily medically managed because renal angioplasty and stenting offers no benefit over optimal medical therapy alone.</li> <li>• Renal artery angioplasty and stenting for atherosclerotic hemodynamically significant renal artery stenosis could be considered for patients with uncontrolled hypertension resistant to maximally tolerated pharmacotherapy, progressive renal function loss, and acute pulmonary edema.</li> <li>• Patients with confirmed renal fibromuscular dysplasia (FMD) should be referred to a hypertension specialist.</li> <li>• Renal artery angioplasty without stenting is recommended for treatment of FMD-related renal artery stenosis. Stenting is not recommended unless needed because of a periprocedural dissection. Surgical revascularization should be considered in cases of complex lesions less amendable to angioplasty, stenosis associated with complex aneurysm, and restenosis despite two unsuccessful attempts of angioplasty.</li> </ul>
	<p><u>Treatment of hypertension in association with diabetes mellitus</u></p>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Persons with diabetes mellitus should be treated to attain SBP of &lt;130 mmHg and DBP of &lt;80 mmHg.</li> <li>• For persons with cardiovascular or kidney disease, including microalbuminuria, or with cardiovascular risk factors in addition to diabetes and hypertension, an ACE inhibitor or an ARB is recommended as initial therapy.</li> <li>• For persons with diabetes and hypertension not included in other guidelines in this section, appropriate choices include (in alphabetical order): ACE inhibitors, ARBs, dihydropyridine CCBs, and thiazide/thiazide-like diuretics.</li> <li>• If target BP levels are not achieved with standard-dose monotherapy, additional antihypertensive therapy should be used. For persons in whom combination therapy with an ACE inhibitor is being considered, a dihydropyridine CCB is preferable to a thiazide/thiazide-like diuretic.</li> </ul> <p><u>Resistant hypertension</u></p> <ul style="list-style-type: none"> <li>• Resistant hypertension is defined as BP above target despite three or more BP-lowering drugs at optimal doses preferably including a diuretic (and usually a renin-angiotensin-aldosterone system blocker and a CCB).</li> <li>• Accurate office and out-of-office BP measurement is essential.</li> <li>• Other reasons for apparent resistant hypertension should be eliminated before diagnosing true resistant hypertension, including nonadherence, white coat effect, and secondary hypertension.</li> <li>• Pharmacotherapy with the additional use of spironolactone, bisoprolol, doxazosin, amiloride, eplerenone, or clonidine with the baseline regimen decreases BP significantly, with the greatest BP-lowering shown with spironolactone.</li> <li>• Patients with resistant hypertension should be referred to providers with expertise in diagnosis and management of hypertension.</li> </ul> <p><u>Hypertension and pediatrics</u></p> <ul style="list-style-type: none"> <li>• BP should be measured regularly in children three years of age or older; the auscultatory method is the gold-standard at present.</li> <li>• Initial therapy should be monotherapy, with an ACE inhibitor or ARB (not first-line in black children), or a long-acting dihydropyridine CCB.</li> <li>• The treatment goal is systolic and diastolic office BP and/or ABPM &lt; 95th percentile or &lt;90<sup>th</sup> percentile in children with risk factors or target organ damage.</li> <li>• Complex cases should be referred to an expert in pediatric hypertension.</li> </ul> <p><u>Hypertension and pregnancy</u></p> <ul style="list-style-type: none"> <li>• Up to 7% of pregnancies are complicated by a hypertensive disorder of pregnancy, and approximately 5% of women will have chronic hypertension when they become pregnant.</li> <li>• The prevalence of hypertension in pregnancy is expected to increase with women becoming pregnant later in their reproductive years and the increasing prevalence of cardiovascular comorbidities such as increased preconception body mass index and maternal diabetes.</li> <li>• The possibility of pregnancy should be considered when managing women with hypertension who are of reproductive age.</li> <li>• Preconception counselling should be offered to all women with hypertension who are considering pregnancy.</li> <li>• ACE inhibitor and ARB therapy should be avoided before conception and during pregnancy unless there is a compelling indication for their use (i.e., proteinuric kidney disease).</li> <li>• Hypertension during pregnancy can increase the risk of adverse maternal and fetal outcomes, including an increased risk of preeclampsia, placental abruption,</li> </ul>

Clinical Guideline	Recommendations
	<p>prematurity, small for gestational age infants, stillbirth, and maternal renal and retinal injury, thus generally requires involvement of an interdisciplinary team including obstetrical care providers.</p> <ul style="list-style-type: none"> <li>• Antihypertensive therapy is recommended for average SBP measurements of <math>\geq 140</math> mmHg or DBP measurements of <math>\geq 90</math> mmHg in pregnant women with chronic hypertension, gestational hypertension, or preeclampsia. Initial antihypertensive therapy should be monotherapy from the following first-line drugs: oral labetalol, oral methyldopa, long-acting oral nifedipine, or other oral <math>\beta</math>-blockers (acebutolol, metoprolol, pindolol, and propranolol). Other antihypertensive drugs can be considered as second-line drugs including: clonidine, hydralazine, and thiazide diuretics.</li> <li>• Women with severe hypertension with SBP <math>\geq 160</math> mmHg or DBP <math>\geq 110</math> mmHg in pregnancy or postpartum require urgent antihypertensive therapy because it is considered an obstetrical emergency.</li> <li>• Antihypertensive drugs used in breastfeeding women include: labetalol, methyldopa, long-acting nifedipine, enalapril, or captopril.</li> </ul>
<p>European Society of Hypertension/ European Society of Cardiology: <b>2018 Guidelines for the management of arterial hypertension (2018)</b><sup>20</sup></p>	<p><u>Treatment strategies and choice of antihypertensive drugs</u></p> <ul style="list-style-type: none"> <li>• Diuretics (including thiazides, chlorthalidone, and indapamide), <math>\beta</math>-blockers, calcium channel blocker (CCB), angiotensin-converting enzyme (ACE) inhibitors, and angiotensin receptor blockers (ARBs) are all suitable for the initiation and maintenance of antihypertensive treatment, either as monotherapy or in some combinations.</li> <li>• Some agents should be considered as the preferential choice in specific conditions because used in trials in those conditions or because of greater effectiveness in specific types of organ damage. Preferred combinations should comprise a renin-angiotensin system (RAS) blocker (either an ACE inhibitor or an ARB) with a CCB or diuretic.</li> <li>• It is recommended that beta-blockers are combined with any of the other major drug classes when there are specific clinical situations, e.g. angina, post-myocardial infarction, heart failure, or heart rate control.</li> <li>• Initiation of antihypertensive therapy with a two-drug combination may be considered in patients with markedly high baseline blood pressure (BP) or at high cardiovascular (CV) risk.</li> <li>• The combination of two antagonists of the RAS is not recommended and should be discouraged.</li> <li>• Other drug combinations should be considered and probably are beneficial in proportion to the extent of BP reduction. However, combinations that have been successfully used in trials may be preferable.</li> <li>• Combinations of two antihypertensive drugs at fixed doses in a single tablet may be recommended and favored, because reducing the number of daily pills improves adherence, which is low in patients with hypertension. Exceptions are frail older patients and those at low risk and with grade one hypertension (particularly if systolic BP is <math>&lt; 150</math> mmHg).</li> <li>• It is recommended that if BP is not controlled with a three-drug combination, treatment should be increased by the addition of spironolactone or, if not tolerated, other diuretics such as amiloride or higher doses of other diuretics, a beta-blocker, or an alpha-blocker.</li> </ul> <p><u>Treatment strategies in white-coat and masked hypertension</u></p> <ul style="list-style-type: none"> <li>• In white-coat hypertensives without additional risk factors, therapeutic intervention may be limited to lifestyle changes only, but this decision should be accompanied by close follow-up.</li> <li>• In white-coat hypertensives with a higher CV risk or hypertension-mediated organ damage, drug treatment may be considered in addition to lifestyle changes.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In masked hypertension, both lifestyle measures and antihypertensive drug treatment should be considered, because this type of hypertension has been consistently found to have a CV risk very close to that of in- and out-of-office hypertension.</li> <li>• Antihypertensive drug up-titration should be considered in treated patients whose out-of-office BP is not controlled (i.e., masked uncontrolled hypertension), because of the high CV risk of these patients.</li> </ul> <p><u>Antihypertensive treatment strategies in the elderly</u></p> <ul style="list-style-type: none"> <li>• It is recommended that older patients (<math>\geq 65</math> years) are treated with the same recommendations in non-older patient population. In very old patients (<math>\geq 80</math> years), it may be appropriate to initiate treatment with monotherapy.</li> <li>• In all older patients, when combination therapy is used, it is recommended that this is initiated at the lowest available doses. In all older patients, and especially very old or frail patients, the possible occurrence of postural BP should be closely monitored and symptoms of possible hypotensive episodes checked by ambulatory blood pressure monitoring.</li> <li>• Unless required for concomitant diseases, loop diuretics and alpha-blockers should be avoided because of their association with injurious falls.</li> <li>• Renal function should be frequently assessed to detect possible increases in serum creatinine and reductions in estimated glomerular filtration rate (eGFR) as a result of BP-related reductions in renal perfusion.</li> <li>• When treated, BP should be lowered to a systolic value of 130 to 139 mmHg and a diastolic value of <math>&lt; 80</math> mmHg if tolerated. Treated values of <math>&lt; 130</math> mmHg should be avoided.</li> </ul> <p><u>Treatment strategies in hypertensive women</u></p> <ul style="list-style-type: none"> <li>• Hormone therapy and selective estrogen receptor modulators are not recommended and should not be used for primary or secondary prevention of CVD.</li> <li>• In women with gestational hypertension, pre-existing hypertension superimposed by gestational hypertension, or with hypertension and subclinical organ damage or symptoms, initiation of drug treatments is recommended when SBP is <math>\geq 140</math> mmHg or DBP <math>\geq 90</math> mmHg. In all other cases, initiation of drug treatment is recommended when SBP is <math>\geq 150</math> mmHg or DBP is <math>\geq 95</math> mmHg.</li> <li>• Methyldopa, labetalol, and CCBs are recommended as the drugs of choice for the treatment of hypertension in pregnancy.</li> <li>• ACE inhibitors, ARBs, or direct renin inhibitors are not recommended during pregnancy.</li> <li>• SBP <math>\geq 170</math> mmHg or DBP <math>\geq 110</math> mmHg in a pregnant woman is an emergency, and admission to hospital is recommended.</li> <li>• In severe hypertension, drug treatment with intravenous (IV) labetalol, oral methyldopa, or nifedipine is recommended.</li> <li>• The recommended treatment for hypertensive crisis is IV labetalol or nicardipine and magnesium.</li> <li>• In pre-eclampsia associated with pulmonary edema, nitroglycerin given as an IV infusion is recommended.</li> <li>• In women with gestational hypertension or mild-pre-eclampsia, delivery is recommended at 37 weeks.</li> <li>• It is recommended to expedite delivery in pre-eclampsia with adverse conditions, such as visual disturbances or hemostatic disorders</li> <li>• In women at high risk of pre-eclampsia, provided they are at low risk of gastrointestinal hemorrhage, treatment with low dose aspirin from 12 weeks until delivery may be considered.</li> <li>• Methyldopa, labetalol, and nifedipine should be considered preferential</li> </ul>

Clinical Guideline	Recommendations
	<p>antihypertensive drugs in pregnancy. Intravenous labetalol or infusion of nitroprusside should be considered in case of emergency (pre-eclampsia).</p> <p><u>Treatment strategies in patients with diabetes</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive drug treatment is recommended for people with diabetes when office BP is <math>\geq 140/90</math> mmHg.</li> <li>• A SBP goal <math>&lt; 130</math> mmHg is recommended in patients with diabetes and <math>&lt; 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg.</li> <li>• In older people, the target SBP range is 130 to 139 mmHg.</li> <li>• The DBP target in patients with diabetes is recommended to be <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• It is recommended to initiate treatment with a combination of a RAS blocker with a CCB or thiazide/thiazide-like diuretic.</li> <li>• It is recommended that individual drug choice takes comorbidities into account.</li> <li>• Simultaneous administration of two blockers of the RAS is not recommended and should be avoided in patients with diabetes.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with nephropathy</u></p> <ul style="list-style-type: none"> <li>• In patients with diabetic and non-diabetic CKD, it is recommended that an office BP of <math>\geq 140/90</math> mmHg be treated with lifestyle advice and BP-lowering medication.</li> <li>• In patients with diabetic or non-diabetic CKD, it is recommended to lower SBP to a range of 130 to 139 mmHg. And individualized treatments should be considered according to its tolerability and impact on renal function and electrolytes.</li> <li>• A combination of a RAS blocker with a CCB or a diuretic is recommended as initial therapy.</li> <li>• RAS blockers are more effective in reducing albuminuria than other antihypertensive agents, and are indicated in hypertensive patients in the presence of microalbuminuria or overt proteinuria.</li> <li>• Combination of two RAS blockers, though potentially more effective in reducing proteinuria, is not recommended.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with cerebrovascular disease</u></p> <ul style="list-style-type: none"> <li>• In patients with acute intracerebral hemorrhage, immediate BP lowering is not recommended for patients with SBP <math>&lt; 220</math> mmHg. In patients with SBP <math>\geq 220</math> mmHg, care acute BP lowering with IV therapy to <math>&lt; 180</math> mmHg should be considered.</li> <li>• In acute ischemic stroke, routine BP lowering with antihypertensive therapy is not recommended with the exceptions with the exceptions: in patients with acute ischemic stroke who are eligible for IV thrombolysis, BP should be carefully lowered and maintained at <math>&lt; 180/105</math> mmHg for at least the first 24 hours after thrombolysis; In patients with markedly elevated BP who do not receive fibrinolysis, drug therapy may be considered, based on clinical judgement, to reduce BP by 15% during the first 24 hours after the stroke onset.</li> <li>• In hypertensive patients with an acute cerebrovascular event, antihypertensive treatment is recommended immediately for transient ischemic attack (TIA) and after several days in ischemic stroke.</li> <li>• In all hypertensive patients with ischemic stroke or TIA, an SBP target range of 120 to 130 mmHg should be considered.</li> <li>• The recommended antihypertensive drug treatment strategy for stroke prevention is a RAS blocker plus a CCB or a thiazide-like diuretic.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with heart failure (HF) or left ventricular hypertrophy (LVH)</u></p>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In hypertensive patients with heart failure (with reduced or preserved ejection fraction), BP-lowering treatment should be considered if <math>\geq 140/90</math> mmHg.</li> <li>• In patients with HF<sub>r</sub>EF, it is recommended that BP-lowering treatment comprises an ACE inhibitor or ARB, and a beta-blocker and a diuretic and/or mineralocorticoid receptor antagonist (MRA) if required.</li> <li>• Dihydropyridine CCBs may be added if BP control is not achieved.</li> <li>• In patients with HF<sub>p</sub>EF, BP treatment threshold and target values should be the same as for HF<sub>r</sub>EF).</li> <li>• Because no specific drug has proven its superiority, all major agents can be used.</li> <li>• In all patients with LVH, it is recommended to treat with a RAS blocker or in combination with a CCB or diuretic and SBP should be lowered to a range of 120 to 130 mmHg.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• In patients with CAD receiving BP-lowering drugs, it is recommended to target SBP to <math>\leq 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg. In older patients, the target is an SBP range of 130 to 140 mmHg. The target DBP is <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• In hypertensive patients with a history of myocardial infarction, beta-blockers and RAS blockers are recommended as part of treatment.</li> <li>• In patients with asymptomatic angina, beta-blockers and/or CCBs are recommended.</li> </ul>
<p>National Institute for Health and Clinical Excellence: <b>Hypertension in adults: diagnosis and management (2019)</b><sup>21</sup></p>	<p><u>Choosing antihypertensive drug treatment (for people with or without type II diabetes)</u></p> <ul style="list-style-type: none"> <li>• Where possible, recommend treatment with drugs taken only once a day.</li> <li>• Prescribe non-proprietary drugs where these are appropriate and minimize cost.</li> <li>• Offer people with isolated systolic hypertension (systolic blood pressure <math>\geq 160</math> mmHg) the same treatment as people with both raised systolic and diastolic blood pressure.</li> <li>• Offer antihypertensive drug treatment to women of child-bearing potential with diagnosed hypertension in line with recommendations in this guideline. For women considering pregnancy or who are pregnant or breastfeeding, manage hypertension in line with the recommendations on Management of pregnancy with chronic hypertension and Breastfeeding in 'Hypertension in pregnancy'.</li> <li>• When choosing antihypertensive drug treatment for adults of black African or African-Caribbean family origin, consider an angiotensin II receptor blocker, in preference to an angiotensin-converting enzyme inhibitor.</li> </ul> <p><u>Step one treatment</u></p> <ul style="list-style-type: none"> <li>• Patients <math>&lt; 55</math> years of age should be offered a step one antihypertensive with an angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB).</li> <li>• Offer an ACE inhibitor or an ARB to adults starting step 1 antihypertensive treatment who have type II diabetes and are of any age or family origin or those aged <math>&lt; 55</math> years but not of black African or African-Caribbean family origin.</li> <li>• If an ACE inhibitor is not tolerated, offer an ARB.</li> <li>• Do not combine an ACE inhibitor with an ARB for the treatment of hypertension.</li> <li>• Offer a calcium channel blocker (CCB) to adults starting step 1 antihypertensive treatment who are <math>&gt; 55</math> years of age and do not have diabetes and are of black African or African-Caribbean family origin and do not have type II diabetes and of any age.</li> <li>• If a CCB is not suitable, for example because of edema or intolerance, or if</li> </ul>

Clinical Guideline	Recommendations
	<p>there is evidence of heart failure or a high risk of heart failure, offer a thiazide-like diuretic.</p> <ul style="list-style-type: none"> <li>• If diuretic treatment is to be initiated or changed, offer a thiazide-like diuretic, such as indapamide in preference to a conventional thiazide diuretic such as bendroflumethiazide or hydrochlorothiazide.</li> <li>• For adults with hypertension who are already receiving treatment with bendroflumethiazide or hydrochlorothiazide, who have stable, well-controlled blood pressure, continue with their treatment.</li> </ul> <p><u>Step two treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering next step treatment for hypertension discuss with the person if they are taking their medicine as prescribed and support adherence in line with NICE's guideline on "Medicines adherence: involving patients decisions about prescribed medicines and supporting adherence".</li> <li>• If hypertension is not controlled with a step one treatment of an ACE inhibitor or ARB, offer choice of one of the following drugs in addition to the step one treatment: a CCB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults taking step one treatment of a CCB, offer the choice of one of the following drugs in addition to the step one treatment: an ACE inhibitor or an ARB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults of black African or African-Caribbean family origin who do not have type 2 diabetes taking step one treatment, consider an ARB, in preference to an ACE inhibitor, in addition to step one treatment.</li> </ul> <p><u>Step three treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering step three treatment, review the person's medications to ensure they are being taken at the optimal doses and discuss adherence (see recommendation under step two).</li> <li>• If hypertension is not controlled in adults taking step two treatment, offer a combination of an ACE inhibitor or ARB and a CCB and a thiazide-like diuretic.</li> </ul> <p><u>Step four treatment</u></p> <ul style="list-style-type: none"> <li>• If hypertension is not controlled in adults taking the optimal tolerated doses of an ACE inhibitor or an ARB plus a CCB and a thiazide-like diuretic, regard them as having resistant hypertension.</li> <li>• Before considering further treatment for a person with resistant hypertension, confirm elevated clinic blood pressure measurements using ambulatory or home blood pressure recordings, assess for postural hypotension, and discuss adherence.</li> <li>• For people with confirmed resistant hypertension, consider adding a fourth antihypertensive drug as step four treatment or seeking specialist advice.</li> <li>• Consider further diuretic therapy with low-dose spironolactone for adults with resistant hypertension starting step four treatment who have a blood potassium level of 4.5 mmol/l or less. Use particular caution in people with a reduced estimated glomerular filtration rate because they have an increased risk of hyperkalemia.</li> <li>• When using further diuretic therapy for step four treatment of resistant hypertension, monitor blood sodium and potassium and renal function within one month of starting treatment and repeat as needed thereafter.</li> <li>• Consider an alpha-blocker or beta-blocker for adults with resistant hypertension starting step four treatment who have a blood potassium level of more than 4.5 mmol/l.</li> <li>• If blood pressure remains uncontrolled in people with resistant hypertension</li> </ul>

Clinical Guideline	Recommendations
	taking the optimal tolerated doses of four drugs, seek specialist advice.
<p>American College of Cardiology/American Heart Association Task Force: <b>Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults (2017)</b><sup>22</sup></p>	<p><u>Initiation of Blood Pressure (BP) Treatment for Overall Cardiovascular Disease (CVD) Risk</u></p> <ul style="list-style-type: none"> <li>• Use of BP-lowering medications is recommended for secondary prevention of recurrent CVD events in patients with clinical CVD and an average systolic blood pressure (SBP) <math>\geq 130</math> mmHg or an average diastolic blood pressure (DBP) of <math>\geq 80</math> mmHg and for primary prevention in adults with an estimated 10-year atherosclerotic cardiovascular disease (ASCVD) risk of <math>\geq 10\%</math> and an average SBP of <math>\geq 130</math> mmHg or an average <math>\geq 80</math> mmHg.</li> <li>• Use of BP-lowering medication is recommended for primary prevention of CVD in adults with no history of CVD and with an estimated 10-year ASCVD risk <math>&lt; 10\%</math> and an SBP of <math>\geq 140</math> mmHg or a DBP of <math>\geq 90</math> mmHg.</li> <li>• Simultaneous use of an angiotensin converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), and/or renin inhibitor is potentially harmful and is not recommended to treat adults with hypertension.</li> <li>• For adults with confirmed hypertension and known CVD or 10-year ASCVD risk of <math>\geq 10\%</math>, a BP target <math>&lt; 130/80</math> mmHg is recommended. For adults with confirmed hypertension without additional markers of increased CVD risk, a BP target <math>&lt; 130/80</math> mmHg may be reasonable.</li> <li>• For initiation of antihypertensive drug therapy, first-line agents include thiazide diuretics, calcium channel blockers (CCBs), and ACE inhibitors or ARBs.</li> <li>• Initiation of antihypertensive drug therapy with two first-line agents of different classes, either as separate agents or in a fixed-dose combination, is recommended in adults with stage 2 hypertension and an average BP <math>&gt; 20/10</math> mmHg above their BP target.</li> <li>• Initiation of antihypertensive drug therapy with a single antihypertensive drug is reasonable in adults with stage 1 hypertension and BP goal <math>&lt; 130/80</math> mmHg with dosage titration and sequential addition of other agents to achieve the BP target.</li> </ul> <p><u>Stable Ischemic Heart Disease (SIHD)</u></p> <ul style="list-style-type: none"> <li>• In adults with SIHD and hypertension, a BP target <math>&lt; 130/80</math> is recommended.</li> <li>• Adults with SIHD and hypertension (BP <math>\geq 130/80</math> mmHg) should be treated with medications [e.g., guideline-directed medical therapy (GDMT) beta-blockers, ACE inhibitors, or ARBs] for compelling indications [e.g., previous myocardial infarction (MI), stable angina] as first-line therapy, with the addition of other drugs (e.g., dihydropyridine CCBs, thiazide diuretics, and/or mineralocorticoid receptor antagonists) as needed to further control hypertension.</li> <li>• In adults with SIHD with angina and persistent uncontrolled hypertension, the addition of dihydropyridine CCBs to GDMT beta-blockers is recommended.</li> <li>• In adults who have had a MI or acute coronary syndrome, it is reasonable to continue GDMT beta-blockers beyond three years as long-term therapy for hypertension.</li> <li>• Beta-blockers and/or CCBs might be considered to control hypertension in patients with coronary artery disease (CAD) had an MI more than three years ago and have angina.</li> </ul> <p><u>Heart Failure</u></p> <ul style="list-style-type: none"> <li>• In adults with increased risk of HF, the optimal BP in those with hypertension should be <math>&lt; 130</math> mmHg.</li> <li>• Adults with HFrEF and hypertension should be prescribed GDMT titrated to attain a BP <math>&lt; 130/80</math> mmHg.</li> <li>• Non-dihydropyridine CCBs are not recommended in the treatment of hypertension in adults with HFrEF.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In adults with HFpEF who present with symptoms of volume overload, diuretics should be prescribed to control hypertension.</li> <li>• Adults with HFpEF and persistent hypertension after management of volume overload should be prescribed ACE inhibitors or ARBs and beta-blockers titrated to attain SBP &lt;130 mmHg.</li> </ul> <p><u>CKD</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and CKD should be treated to a BP goal &lt;130/80 mmHg.</li> <li>• In adults with hypertension and CKD [stage 3 or higher or stage 1 or 2 with albuminuria (<math>\geq 300</math> mg/d, or <math>\geq 300</math> mg/g albumin-to-creatinine ratio or the equivalent in the first morning void)], treatment with an ACE inhibitor is reasonable to slow kidney disease progression. Treatment with an ARB may be reasonable if an ACE inhibitor is not tolerated.</li> <li>• After kidney transplantation, it is reasonable to treat patients with hypertension to a BP goal &lt;130/80 mmHg and with a CCB on the basis of improved glomerular filtration rate (GFR) and kidney survival.</li> </ul> <p><u>Cerebrovascular Disease</u></p> <ul style="list-style-type: none"> <li>• In adults with intracerebral hemorrhage (ICH) who present with SBP &gt;220 mmHg, it is reasonable to use continuous intravenous (IV) drug infusion and close BP monitoring to lower levels. Immediate lowering of SBP to &lt;140 mmHg in adults with spontaneous ICH who present within six hours of the acute event and have an SBP between 150 mmHg and 220 mmHg is not of benefit to reduce death or severe disability and can be potentially harmful.</li> <li>• Adults with acute ischemic stroke and elevated BP who are eligible for treatment with IV tissue plasminogen activator (tPA) should have their BP slowly lowered to &lt;185/110 mmHg before thrombolytic therapy is initiated.</li> <li>• In adults with an acute ischemic stroke, BP should be &lt;185/110 mmHg before administration of IV tPA and should be maintained below 180/105 mmHg for at least the first 24 hours after initiation drug therapy.</li> <li>• Starting or restarting antihypertensive therapy during hospitalization in patients with BP &gt;140/90 mmHg who are neurologically stable is safe and reasonable to improve long-term BP control, unless contraindicated.</li> <li>• In patient with BP <math>\geq 220/120</math> mmHg who did not receive IV alteplase or endovascular treatment and have no comorbid conditions requiring acute antihypertensive treatment, the benefit of initiating or reinitiating treatment of hypertension within the first 48 to 72 hours is uncertain. It might be reasonable to lower BP by 15% during the first 24 hours after onset of stroke. In patients with BP &lt;220/120 mmHg with the same conditions, initiating or reinitiating treatment of hypertension within the first 48 to 72 hours after an acute ischemic stroke is not effective to prevent death or dependency.</li> <li>• Adults with previously treated stroke or transient ischemic attack should be restarted on antihypertensive treatment after the first few days of the index event to reduce the risk of recurrent stroke and other vascular events. Treatment with a thiazide diuretic, ACE inhibitor, or ARB, or combination treatment consisting of a thiazide diuretic plus ACE inhibitor, is useful.</li> <li>• Adults not previously treated for hypertension who experienced a stroke or transient ischemic attack and have an established BP <math>\geq 140/90</math> mmHg should be prescribed antihypertensive treatment a few days after the index event to reduce the risk of recurrent stroke and other vascular event.</li> <li>• For adults who experience a stroke or transient ischemic attack, selection of specific drugs should be individualized on the basis of patient comorbidities and agent pharmacological class.</li> <li>• For adults who experience a stroke or transient ischemic attack, a BP goal</li> </ul>

Clinical Guideline	Recommendations
	<p>&lt;130/80 mmHg may be reasonable.</p> <ul style="list-style-type: none"> <li>For adults with a lacunar stroke, a target SBP goal &lt;130 mmHg may be reasonable.</li> <li>In adults previously untreated for hypertension who experience an ischemic stroke or transient ischemic attack and have an SBP &lt;140 mmHg and a DBP &lt;90 mmHg, the usefulness of initiating antihypertensive treatment is not well established.</li> </ul> <p><u>Peripheral Artery Disease (PAD)</u></p> <ul style="list-style-type: none"> <li>Adults with hypertension and PAD should be treated similarly to patients with hypertension without PAD.</li> </ul> <p><u>Diabetes Mellitus (DM)</u></p> <ul style="list-style-type: none"> <li>In adults with DM and hypertension, antihypertensive drug treatment should be initiated at a BP of <math>\geq 130/80</math> mmHg with a treatment goal &lt;130/80 mmHg.</li> <li>In adults with DM and hypertension, all first-line classes of antihypertensive agents (i.e., diuretics, ACE inhibitors, ARBs, and CCBs) are useful and effective.</li> <li>In adults with DM and hypertension, ACE inhibitors or ARBs may be considered in the presence of albuminuria.</li> </ul> <p><u>Atrial Fibrillation, Valvular Heart Disease, and Aortic disease</u></p> <ul style="list-style-type: none"> <li>Treatment of hypertension can be useful for prevention of recurrence of AF.</li> <li>In adults with asymptomatic aortic stenosis, hypertension should be treated with pharmacotherapy, starting at a low dose and gradually titrating upward as needed.</li> <li>In patients with chronic aortic insufficiency, treatment of systolic hypertension with agents that do not slow the heart rate (i.e., avoid beta-blockers) is reasonable.</li> <li>Beta-blockers are recommended as the preferred antihypertensive agents in patients with hypertension and thoracic aortic disease.</li> </ul> <p><u>Racial and Ethnic Differences in Treatment</u></p> <ul style="list-style-type: none"> <li>In black adults with hypertension but without HF or CKD, including those with DM, initial antihypertensive treatment should include a thiazide-type diuretic or CCB. Two or more antihypertensive medications are recommended to achieve a BP target &lt;130/80 mmHg in most adults with hypertension, especially in black adults with hypertension.</li> </ul> <p><u>Pregnancy</u></p> <ul style="list-style-type: none"> <li>Women with hypertension who become pregnant, or are planning to become pregnant, should be transitioned to methyldopa, nifedipine, and/or labetalol during pregnancy.</li> <li>Women with hypertension who become pregnant should not be treated with ACE inhibitors, ARBs, or direct renin inhibitors.</li> </ul> <p><u>Older Persons</u></p> <ul style="list-style-type: none"> <li>Treatment of hypertension with an SBP treatment goal &lt;130 mmHg is recommended for noninstitutionalized ambulatory community-dwelling adults (<math>\geq 65</math> years of age) with an average SBP of <math>\geq 130</math> mmHg.</li> <li>For older adults (<math>\geq 65</math> years of age) with hypertension and a higher burden of comorbidity and limited life expectancy, clinical judgment, patient preference, and a team-based approach to assess risk/benefit is reasonable for decisions regarding intensity of BP lowering and choice of antihypertensive drugs.</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Hypertensive Crises</u></p> <ul style="list-style-type: none"> <li>In adults with a hypertensive emergency, admission to an intensive care unit is recommended for continuous monitoring of BP and target organ damage and for parenteral administration of an appropriate agent.</li> <li>For adults with a compelling condition (i.e., aortic dissection, severe pre-eclampsia or eclampsia, or pheochromocytoma crisis), SBP should be reduced to &lt;140 mmHg during the first hour and to &lt;120 mmHg in aortic dissection.</li> <li>For adults without a compelling condition, SBP should be reduced by no more than 25% within the first hours; then, if stable, to 160/100 mmHg within the next two to six hours; and then cautiously to normal during the following 24 to 48 hours.</li> </ul> <p><u>Cognitive Decline and Dementia</u></p> <ul style="list-style-type: none"> <li>In adults with hypertension, BP lowering is reasonable to prevent cognitive decline and dementia.</li> </ul> <p><u>Patients Undergoing Surgical Procedures</u></p> <ul style="list-style-type: none"> <li>In patients with hypertension undergoing major surgery who have been on beta-blockers chronically, beta-blockers should be continued.</li> <li>In patients with hypertension undergoing planned elective major surgery, it is reasonable to continue medical therapy for hypertension until surgery.</li> <li>In patients with hypertension undergoing major surgery, discontinuation of ACE inhibitors or ARBs perioperatively may be considered.</li> <li>In patients with planned elective major surgery and SBP <math>\geq</math>180 mmHg or DBP <math>\geq</math>110 mmHg, deferring surgery may be considered.</li> <li>For patients undergoing surgery, abrupt pre-operative discontinuation of beta-blockers or clonidine is potentially harmful.</li> <li>Beta-blockers should not be started on the day of surgery in beta-blocker-naïve patients.</li> <li>Patients with intraoperative hypertension should be managed with IV medications until such time as oral medications can be resumed.</li> </ul>
<p>International Society on Hypertension in Blacks: <b>Management of High Blood Pressure in Blacks (2010)</b><sup>23</sup></p>	<ul style="list-style-type: none"> <li>To attain and maintain blood pressure (BP) below target levels, multiple antihypertensive drugs will be required in most hypertensive blacks.</li> <li>Use of two-drug combination therapy when SBP is &gt;15 mm Hg and/or DBP is &gt;10 mm Hg above goal levels is increasingly recommended as first-line therapy.</li> <li>Two-drug regimens have generally contained a thiazide-type diuretic; however, the combination of a calcium channel blocker (CCB) with either an ACE inhibitor or an ARB has been shown equally efficacious in BP lowering but with demonstrated superiority (CCB+ACE) for hard clinical outcomes compared with the same ACE inhibitor plus a thiazide-type diuretic.</li> <li>In secondary prevention patients, the combination therapy should include a drug(s) with the appropriate compelling indications.</li> <li>Certain classes of antihypertensive medications, specifically diuretics and CCBs, lower BP on average more than <math>\beta</math>-blockers and renin-angiotensin system (RAS) blockers in black patients when used as monotherapies.</li> <li>In the absence of compelling indications, when BP is near goal levels, monotherapy with a diuretic or a CCB is preferred.</li> <li>Lifestyle modifications should be initiated in all patients with hypertension, whether or not pharmacotherapy is planned.</li> <li>ACE inhibitors or ARBs are recommended as alternative monotherapy options in the treatment of hypertension in blacks. The rationale for their lower tier monotherapy recommendation is because they have consistently achieved lesser average reductions in BP relative to that observed with monotherapy using either a diuretic or CCB.</li> </ul>

Clinical Guideline	Recommendations
<p>Kidney Disease Improving Clinical Outcomes Group: <b>KDIGO Clinical Practice Guideline for the Management of Blood Pressure in Chronic Kidney Disease (2021)</b><sup>24</sup></p>	<p><u>Blood pressure measurement</u></p> <ul style="list-style-type: none"> <li>The Work Group recommends standardized office blood pressure (BP) measurement in preference to routine office BP measurements for the management of high BP in adults.</li> <li>The Work Group suggests that out-of-office BP measurements with ambulatory BP monitoring (ABPM) or home BP monitoring (HBPM) be used to complement standardized office BP readings for the management of high BP.</li> </ul> <p><u>Lifestyle interventions for lowering BP in patients with chronic kidney disease (CKD) not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests targeting a sodium intake &lt;2 grams of sodium per day (or &lt;90 mmol of sodium per day, or &lt;5 grams of sodium chloride per day) in patients with high BP and CKD.</li> <li>The Work Group suggests that patients with high BP and CKD be advised to undertake moderate-intensity physical activity for a cumulative duration of at least 150 minutes per week, or to a level compatible with their cardiovascular and physical tolerance.</li> </ul> <p><u>BP management in patients with CKD, with or without diabetes, not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests that adults with high BP and CKD be treated with a target systolic BP (SBP) of &lt;120 mmHg, when tolerated, using standardized office BP measurement.</li> <li>The Work Group recommends starting renin-angiotensin-system inhibitors (RASi) (angiotensin-converting enzyme inhibitor [ACEi] or angiotensin II receptor blocker [ARB]) for people with high BP, CKD, and severely increased albuminuria without diabetes.</li> <li>The Work Group suggests starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately increased albuminuria without diabetes.</li> <li>The Work Group recommends starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately-to-severely increased albuminuria with diabetes.</li> <li>The Work Group recommends avoiding any combination of ACEi, ARB, and direct renin inhibitor (DRI) therapy in patients with CKD, with or without diabetes.</li> </ul> <p><u>BP management in kidney transplant recipients</u></p> <ul style="list-style-type: none"> <li>Treat adult kidney transplant recipients with high BP to a target BP of &lt;130 mmHg systolic and &lt;80 mmHg diastolic using standardized office BP measurement.</li> <li>The Work Group recommends that a dihydropyridine calcium channel blocker (CCB) or an ARB be used as the first-line antihypertensive agent in adult kidney transplant recipients.</li> </ul> <p><u>BP management in children with CKD</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests that in children with CKD, 24-hour mean arterial pressure by ABPM should be lowered to &lt;50<sup>th</sup> percentile for age, sex, and height.</li> </ul>
<p>American Diabetes Association: <b>Standards of Medical Care in Diabetes (2022)</b><sup>25</sup></p>	<p><u>Hypertension/blood pressure control</u></p> <ul style="list-style-type: none"> <li>Blood pressure should be measured at every routine visit. When possible, patients found to have elevated blood pressure (≥140/90) should have blood pressure confirmed using multiple readings, including measurements on a separate day, to diagnose hypertension. Patients with blood pressure ≥180/110 and cardiovascular disease could be diagnosed with hypertension at a single visit.</li> <li>All hypertensive patients with diabetes should monitor their blood pressure at</li> </ul>

Clinical Guideline	Recommendations
	<p>home.</p> <ul style="list-style-type: none"> <li>• For patients with diabetes and hypertension, with diabetes and hypertension, blood pressure targets should be individualized through a shared decision-making process that addresses cardiovascular risk, potential adverse effects of antihypertensive medications, and patient preferences.</li> <li>• For individuals with diabetes and hypertension at higher cardiovascular risk (existing atherosclerotic cardiovascular disease [ASCVD] or 10-year ASCVD risk <math>\geq 15\%</math>), a blood pressure target of <math>&lt;130/80</math> mmHg may be appropriate, if it can be safely attained.</li> <li>• For individuals with diabetes and hypertension at lower risk for cardiovascular disease (10-year atherosclerotic cardiovascular disease risk <math>&lt;15\%</math>), treat to blood pressure target of <math>&lt;140/90</math>.</li> <li>• In pregnant patients with diabetes and preexisting hypertension, a blood pressure target of 110 to 135/85 is suggested in the interest of reducing the risk for accelerated maternal hypertension and minimizing impaired fetal growth.</li> <li>• For patients with blood pressure <math>&gt;120/80</math>, lifestyle intervention consists of weight loss when indicated, a Dietary Approaches to Stop Hypertension (DASH)-style eating pattern including reducing sodium and increasing potassium intake, moderation of alcohol intake, and increased physical activity.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq 140/90</math> mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of pharmacologic therapy to achieve blood pressure goals.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq 160/100</math> mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of two drugs or a single pill combination of drugs demonstrated to reduce cardiovascular events in patients with diabetes.</li> <li>• Treatment for hypertension should include drug classes demonstrated to reduce cardiovascular events in patients with diabetes (ACE inhibitors, angiotensin receptor blockers, thiazide-like diuretics, or dihydropyridine calcium channel blockers). ACE inhibitors or angiotensin receptor blockers are recommended first-line therapy for hypertension in people with diabetes and coronary artery disease.</li> <li>• Multiple-drug therapy is generally required to achieve blood pressure targets (but not a combination of ACE inhibitors and angiotensin receptor blockers).</li> <li>• An ACE inhibitor or angiotensin receptor blocker, at the maximum tolerated dose indicated for blood pressure treatment, is the recommended first-line treatment for hypertension in patients with diabetes and urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine or 30 to 299 mg/g creatinine. If one class is not tolerated, the other should be substituted.</li> <li>• For patients treated with an ACE inhibitor, angiotensin receptor blocker, or diuretic, serum creatinine/estimated glomerular filtration rate and serum potassium levels should be monitored at least annually.</li> <li>• Patients with hypertension who are not meeting blood pressure targets on three classes of antihypertensive medications (including a diuretic) should be considered for mineralocorticoid receptor antagonist therapy.</li> </ul> <p><b>Chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>• At least once a year, assess urinary albumin (e.g., spot urinary albumin-to-creatinine ratio) and estimated glomerular filtration rate in patients with type 1 diabetes with duration of five or more years and in all patients with type 2 diabetes.</li> <li>• Patients with diabetes and urinary albumin <math>\geq 300</math> mg/g creatinine and/ or an estimated glomerular filtration rate 30 to 60 mL/min/1.73 m<sup>2</sup> should be monitored twice annually to guide therapy.</li> <li>• Optimize glucose control to reduce the risk or slow the progression of chronic</li> </ul>

Clinical Guideline	Recommendations
	<p>kidney disease (CKD).</p> <ul style="list-style-type: none"> <li>• For patients with type 2 diabetes and diabetic kidney disease, use of a sodium-glucose cotransporter 2 inhibitor in patients with an estimated glomerular filtration rate <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> and urinary albumin <math>\geq 300</math> mg/g creatinine is recommended to reduce CKD progression and cardiovascular events.</li> <li>• In patients with type 2 diabetes and CKD, consider use of sodium–glucose cotransporter 2 inhibitors additionally for cardiovascular risk reduction when estimated glomerular filtration rate and urinary albumin creatinine are <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> or <math>\geq 300</math> mg/g, respectively.</li> <li>• In patients with CKD who are at increased risk for cardiovascular events or CKD progression and are unable to use a sodium–glucose cotransporter 2 inhibitor, a nonsteroidal mineralocorticoid receptor antagonist (finerenone) is recommended to reduce CKD progression and cardiovascular events.</li> <li>• Optimize blood pressure control and reduce blood pressure variability to reduce the risk or slow the progression of CKD.</li> <li>• Do not discontinue renin-angiotensin system blockade for minor increases in serum creatinine (<math>\leq 30\%</math>) in the absence of volume depletion.</li> <li>• For people with nondialysis-dependent stage 3 or higher CKD, dietary protein intake should be a maximum of 0.8 g/kg body weight per day (the recommended daily allowance). For patients on dialysis, higher levels of dietary protein intake should be considered, since malnutrition is a major problem in some dialysis patients.</li> <li>• In nonpregnant patients with diabetes and hypertension, either an ACE inhibitor or an angiotensin receptor blocker is recommended for those with modestly elevated urinary albumin–to–creatinine ratio (30 to 299 mg/g creatinine) and is strongly recommended for those with urinary albumin–to–creatinine ratio <math>\geq 300</math> mg/g creatinine and/or estimated glomerular filtration rate <math>&lt; 60</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Periodically monitor serum creatinine and potassium levels for the development of increased creatinine or changes in potassium when ACE inhibitors, angiotensin receptor blockers, or diuretics are used.</li> <li>• An ACE inhibitor or an angiotensin receptor blocker is not recommended for the primary prevention of CKD in patients with diabetes who have normal blood pressure, normal urinary albumin–to–creatinine ratio (<math>&lt; 30</math> mg/g creatinine), and normal estimated glomerular filtration rate.</li> <li>• Patients should be referred for evaluation by a nephrologist if they have an estimated glomerular filtration rate <math>&lt; 30</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Promptly refer to a nephrologist for uncertainty about the etiology of kidney disease, difficult management issues, and rapidly progressing kidney disease.</li> </ul>
<p>American Urological Association: <b>Management of Benign Prostatic Hyperplasia/ Lower Urinary Tract Symptoms (2021)</b><sup>8</sup></p>	<p><u>Medical therapy</u></p> <ul style="list-style-type: none"> <li>• Offer one of the following <math>\alpha</math>-blockers as a treatment option for patients with bothersome, moderate to severe lower urinary tract symptoms/benign prostatic hyperplasia (LUTS/BPH): alfuzosin, doxazosin, silodosin, tamsulosin, or terazosin.</li> <li>• When prescribing an <math>\alpha</math>-blocker for the treatment of LUTS/BPH, the choice of <math>\alpha</math>-blocker should be based on patient age and comorbidities, and different adverse event profiles (e.g., ejaculatory dysfunction, changes in blood pressure).</li> <li>• When initiating <math>\alpha</math>-blocker therapy, patients with planned cataract surgery should be informed of the associated risks and be advised to discuss these risks with their ophthalmologists.</li> <li>• For the purpose of symptom improvement, 5<math>\alpha</math>-reductase inhibitor (5-ARI) monotherapy should be used as a treatment option in patients with LUTS/BPH with prostatic enlargement as judged by a prostate volume of <math>&gt; 30</math>cc on imaging, a prostate specific antigen (PSA) <math>&gt; 1.5</math>ng/dL, or palpable prostate enlargement on digital rectal exam (DRE).</li> <li>• 5-ARIs alone or in combination with <math>\alpha</math>-blockers are recommended as a</li> </ul>

Clinical Guideline	Recommendations
	<p>treatment option to prevent progression of LUTS/BPH and/or reduce the risks of urinary retention and need for future prostate-related surgery.</p> <ul style="list-style-type: none"> <li>• Before starting a 5-ARI, clinicians should inform patients of the risks of sexual side effects, certain uncommon physical side effects, and the low risk of prostate cancer.</li> <li>• Clinicians may consider 5-ARIs as a treatment option to reduce intraoperative bleeding and peri- or postoperative need for blood transfusion after transurethral resection of the prostate (TURP) or other surgical intervention for BPH.</li> <li>• For patients with LUTS/BPH irrespective of comorbid erectile dysfunction (ED), 5mg daily tadalafil should be discussed as a treatment option.</li> <li>• 5-ARI in combination with an <math>\alpha</math>-blocker should be offered as a treatment option only to patients with LUTS associated with demonstrable prostatic enlargement as judged by a prostate volume of &gt; 30cc on imaging, a PSA &gt;1.5ng/dL, or palpable prostate enlargement on DRE.</li> <li>• Anticholinergic agents, alone or in combination with an <math>\alpha</math>-blocker, may be offered as a treatment option to patients with moderate to severe predominant storage LUTS.</li> <li>• <math>\beta</math>-3-agonists in combination with an <math>\alpha</math>-blocker may be offered as a treatment option to patients with moderate to severe predominate storage LUTS.</li> <li>• Clinicians should not offer the combination of low-dose daily 5mg tadalafil with <math>\alpha</math>-blockers for the treatment of LUTS/BPH as it offers no advantages in symptom improvement over either agent alone.</li> <li>• Physicians should prescribe an oral <math>\alpha</math>-blocker prior to a voiding trial to treat patients with acute urinary retention (AUR) related to BPH.</li> <li>• Patients newly treated for AUR with <math>\alpha</math>-blockers should complete at least three days of medical therapy prior to attempting trial without a catheter (TWOC). Clinicians should inform patients who pass a successful TWOC for AUR from BPH that they remain at increased risk for recurrent urinary retention.</li> </ul>
<p>European Association of Urology: <b>Non-neurogenic Male LUTS (2021)</b><sup>9</sup></p>	<p><u>Pharmacological treatment</u></p> <ul style="list-style-type: none"> <li>• Offer <math>\alpha</math>1-blockers to men with moderate-to-severe lower urinary tract symptoms (LUTS).</li> <li>• <math>\alpha</math>1-blockers are effective in reducing urinary symptoms (IPSS) and increasing the peak urinary flow rate (Qmax) compared with placebo.</li> <li>• Alfuzosin, terazosin and doxazosin showed a statistically significant increased risk of developing vascular-related events compared with placebo.</li> <li>• Alfuzosin, doxazosin, tamsulosin or terazosin exposure has been associated with an increased risk of intra-operative floppy iris syndrome (IFIS).</li> <li>• Ejaculatory dysfunction is significantly more common with <math>\alpha</math>1-blockers than with placebo, particularly with more selective <math>\alpha</math>1-blockers such as tamsulosin and silodosin.</li> <li>• Use 5<math>\alpha</math>-reductase inhibitors in men who have moderate-to-severe LUTS and an increased risk of disease progression (e.g., prostate volume &gt; 40 mL).</li> <li>• Counsel patients about the slow onset of action of 5<math>\alpha</math>-reductase inhibitors.</li> <li>• Use muscarinic receptor antagonists in men with moderate-to-severe LUTS who mainly have bladder storage symptoms.</li> <li>• Do not use antimuscarinic overactive bladder medications in men with a post-void residual volume &gt; 150 mL.</li> <li>• Use <math>\beta</math>-3 agonists in men with moderate-to-severe LUTS who mainly have bladder storage symptoms.</li> <li>• Use phosphodiesterase type 5 inhibitors in men with moderate-to-severe LUTS with or without erectile dysfunction.</li> <li>• Offer combination treatment with an <math>\alpha</math>1-blocker and a 5<math>\alpha</math>-reductase inhibitor to men with moderate-to-severe LUTS and an increased risk of disease progression (e.g., prostate volume &gt; 40 mL).</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>Use combination treatment of a <math>\alpha 1</math>-blocker with a muscarinic receptor antagonist in patients with moderate-to-severe LUTS if relief of storage symptoms has been insufficient with monotherapy with either drug. Do not prescribe combination treatment in men with a post-void residual volume &gt; 150 mL.</li> </ul>

### III. Indications

The Food and Drug Administration (FDA)-approved indications for the  $\alpha$ -adrenergic blocking agents are noted in Table 3. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 3. FDA-Approved Indications for the Alpha-Adrenergic Blocking Agents<sup>3-6</sup>**

Indication	Doxazosin	Prazosin	Terazosin
<b>Benign Prostatic Hyperplasia</b>			
Treatment of signs and symptoms of benign prostatic hypertension	✓		
Treatment of symptomatic benign prostatic hyperplasia			✓
<b>Hypertension</b>			
Treatment of hypertension	✓ * (immediate-release)	✓ *	✓ *

\*Alone or in combination with other antihypertensive agents.

### IV. Pharmacokinetics

The pharmacokinetic parameters of the  $\alpha$ -adrenergic blocking agents are listed in Table 4.

**Table 4. Pharmacokinetic Parameters of the Alpha-Adrenergic Blocking Agents<sup>2</sup>**

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life (hours)
Doxazosin	IR: 65 ER: 54 to 59	98	Liver, extensive (% not reported)	Renal (9) Feces (63)	IR: 22 ER: 15 to 19
Prazosin	56 to 63	92 to 97	Liver, extensive (% not reported)	Renal (<1) Feces, extensive (% not reported)	2 to 3
Terazosin	90	90 to 94	Liver, extensive (% not reported)	Renal (40) Feces (55 to 60)	9 to 12

ER=extended-release, IR=immediate-release

### V. Drug Interactions

Major drug interactions with the  $\alpha$ -adrenergic blocking agents are listed in Table 5.

**Table 5. Major Drug Interactions with the Alpha-Adrenergic Blocking Agents<sup>2</sup>**

Generic Name(s)	Interaction	Mechanism
Alpha-adrenergic blocking agents (doxazosin, prazosin, terazosin)	Asenapine	Concurrent use of asenapine and alpha-adrenergic antagonists may result in additive hypotensive effect.

Generic Name(s)	Interaction	Mechanism
Alpha-adrenergic blocking agents (doxazosin, prazosin, terazosin)	Phosphodiesterase type 5 Inhibitors	Hypotension may occur when alpha-blockers and phosphodiesterase type 5 inhibitors are co-administered. Alpha-blockers and phosphodiesterase type 5 inhibitors may exert additive pharmacologic activity.
Alpha-adrenergic blocking agents (doxazosin)	Boceprevir	Concurrent use of boceprevir and doxazosin may result in increased doxazosin exposure.

## VI. Adverse Drug Events

The most common adverse drug events reported with the  $\alpha$ -adrenergic blocking agents are listed in Table 6. These agents can cause marked hypotension and syncope with sudden loss of consciousness with the first few doses. This “first-dose” effect can be minimized by administration of the first dose at bedtime. Hypotension and syncope can also occur with dose increases, addition of other antihypertensives, and therapy interruptions. The elderly are more at risk for this adverse reaction.

## VII. Dosing and Administration

The usual dosing regimens for the  $\alpha$ -adrenergic blocking agents are listed in Table 7. Treatment should be initiated at bedtime and at the lowest dose to minimize the likelihood of the “first-dose” effect. Dosages should be titrated up slowly to achieve the desired response. If therapy is interrupted for more than a few days, the initial dosing regimen and titration schedule should be reinstated. Other antihypertensive agents should be added cautiously to reduce the risk of developing significant hypotension.<sup>1-6</sup>

**Table 7. Usual Dosing Regimens for the Alpha-Adrenergic Blocking Agents<sup>1-6</sup>**

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
Doxazosin	<p><u>Benign prostatic hyperplasia:</u> Extended-release: initial, 4 mg once daily; maintenance, 4 to 8 mg daily; maximum, 8 mg/day</p> <p>Tablet: initial, 1 mg once daily; maintenance, 1 to 8 mg once daily; maximum:, 8 mg/day</p> <p><u>Hypertension:</u> Tablet: initial, 1 mg once daily; maintenance, 1 to 16 mg once daily; maximum, 16 mg/day</p>	Safety and efficacy in children have not been established.	<p>Extended-release tablet: 4 mg 8 mg</p> <p>Tablet: 1 mg 2 mg 4 mg 8 mg</p>
Prazosin	<p><u>Hypertension:</u> Capsule: initial, 1 mg two to three times a day; maintenance, 6 to 15 mg/day in divided doses; maximum, 40 mg/day</p>	Safety and efficacy in children have not been established.	<p>Capsule: 1 mg 2 mg 5 mg</p>
Terazosin	<p><u>Benign prostatic hyperplasia:</u> Capsule: initial, 1 mg at bedtime; maintenance, 1 to 10 mg/day; maximum, 20 mg/day</p> <p><u>Hypertension:</u> Capsule: initial, 1 mg at bedtime; maintenance, 1 to 20 mg once daily; maximum, 20 mg/day</p>	Safety and efficacy in children have not been established.	<p>Capsule: 1 mg 2 mg 5 mg 10 mg</p>

## VIII. Effectiveness

Clinical studies evaluating the safety and efficacy of the  $\alpha$ -adrenergic blocking agents are summarized in Table 8.

**Table 8. Comparative Clinical Trials with the Alpha-Adrenergic Blocking Agents**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<b>Benign Prostatic Hyperplasia</b>				
<p>Lee et al.<sup>26</sup> (2011)</p> <p><math>\alpha</math>-adrenergic blocking agent</p> <p>vs</p> <p>no <math>\alpha</math>-adrenergic blocking agent</p> <p>All patients were receiving finasteride.</p> <p>Patients were divided into 2 groups based on treatment pattern (<math>\alpha</math>-adrenergic blocking agent monotherapy vs <math>\alpha</math>-adrenergic blocking agent combined with finasteride) and further divided into 4 subgroups based on severity of storage symptoms (IPSS</p>	<p>MC, RETRO</p> <p>Patients <math>\geq 50</math> years of age with LUTS consistent with moderate to severe BPH</p>	<p>N=1315</p> <p>4 years</p>	<p>Primary: Prostate volume, PSA, IPSS, <math>Q_{max}</math></p> <p>Secondary: Not reported</p>	<p>Primary: All groups showed significant improvements in IPSS total scores, IPSS voiding subscores and QOL at one year (P values not reported). Total IPSS from baseline to year four decreased by -11.5 in group IV compared to -0.18 in group I (P&lt;0.001), -6.1 in group II (P=0.97) and -2.6 in group III (P=0.031). However, IPSS storage subscores only improved in patients with high (<math>\geq 6</math>) storage subscores at baseline (P value not reported). After one year, prostate volume and PSA were reduced by 21.3 and 47.0%, respectively, in the combination groups compared to an increase of 9 and 18%, respectively, in the monotherapy groups (P&lt;0.001 for both).</p> <p>Secondary: Not reported</p>

When stratified according to erectile dysfunction severity, the mean changes in International Index of Erectile Function erectile function domain scores over baseline were: <math>4.3 \pm 6.0</math>, <math>0.3 \pm 5.3</math>, <math>-1.2 \pm 1.6</math> in those participants with severe, moderate, and mild erectile dysfunction, respectively.</p> <p>No serious adverse events were observed during the treatment course in either group.</p>
<p>Sun et al.<sup>28</sup> (abstract) (2010)</p> <p>Doxazosin SR 4 mg QD</p> <p>At week 4, subjects who achieved an increase in <math>Q_{max} \geq 3</math> mL/s and a <math>\geq 30\%</math> reduction in the total IPSS continued on doxazosin SR 4 mg for the remaining 4 weeks; all other subjects were titrated up to 8 mg QD.</p>	<p>OL, PM</p> <p>Taiwanese males with BPH</p>	<p>N=80</p> <p>8 weeks</p>	<p>Primary: Change from baseline <math>Q_{max}</math> and IPSS</p> <p>Secondary: Safety</p>	<p>Primary Endpoints: Baseline <math>Q_{max}</math> and IPSS were <math>10.7 \pm 3.4</math> mL/s and <math>20.6 \pm 5.4</math>, respectively. At week eight, a significant increase from baseline in <math>Q_{max}</math> of <math>3.3 \pm 4.6</math> mL/s (95% CI, 2.2 to 4.4, <math>P &lt; 0.001</math>) and a significant decrease in total IPSS of <math>-8.9 \pm 7.0</math> (95% CI, -10.5 to -7.3; <math>P &lt; 0.001</math>) was observed.</p> <p>Secondary Endpoints: The most common treatment-related adverse event was dizziness.</p>
<p>Kirby et al.<sup>29</sup> (2001)</p> <p>Doxazosin vs</p>	<p>2 DB, MC, PG, RCT</p> <p>Men 50 to 80 years of age with BPH</p>	<p>N=1,475</p> <p>17 weeks</p>	<p>Primary: Change from baseline in IPSS and <math>Q_{max}</math></p> <p>Secondary: Sexual function,</p>	<p>Primary: A 45% significant decrease from baseline in IPSS was attained with both formulations of doxazosin compared to a 34% decrease with placebo after 13 weeks (<math>P &lt; 0.001</math> vs placebo). Doxazosin SR was as effective as doxazosin in improving IPSS with a least squares mean difference of 0.07 (SEM, 0.28; 95% CI, -0.47 to 0.61; <math>P = 0.799</math>).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
doxazosin SR  vs  placebo  Comparison with placebo was evaluated in 1 of the 2 trials.			tolerability	Effect on Q <sub>max</sub> was also comparable between the two doxazosin formulations; a least square mean difference of 0.19 (SEM, 0.23; 95% CI, -0.27 to 0.64; P=0.426) was reported. The improvements were significantly greater compared to placebo (P<0.001 for both).  Secondary: Only the non-PC trial evaluated sexual function. Both formulations of doxazosin demonstrated modest but significant improvements in sexual function from baseline as measured by the IIEF (P≤0.001 for doxazosin SR and P<0.05 for doxazosin).  Forty one percent of patients receiving doxazosin SR, 54% of patients receiving doxazosin and 39% of patients receiving placebo experienced adverse events (P<0.001 for differences among treatments). Headache, dizziness, respiratory tract infections and asthenia were the most frequently reported side effects of active treatment.
Keten et al. <sup>30</sup> (2015)  Doxazosin XL 4 mg (group 1)  vs  doxazosin XL 8 mg (group 2)  Patients with an inadequate response to 4 mg treatment were switched to 8 mg after one month (group 1b)	PRO  Patients aged >45 years, with a total PSA <4 ng/mL, IPSS of >7, and Q <sub>max</sub> ≤15 mL/s	N=162  4 months	Primary: IPSS, Q <sub>max</sub> , quality of life (QoL) score  Secondary: Not reported	Primary: From the time of presentation to the first month follow-up, the IPSS and QoL values had decreased more in group 2 compared with group 1 (P <sub>IPSS</sub> =0.028, P <sub>Q<sub>max</sub></sub> =0.206, P <sub>QoL</sub> =0.038, and P <sub>PVR</sub> =0.070).  The comparison of the patients in Group 1b who used 4 and 8 mg doxazosin XL for one month showed that during the use of 4 mg doxazosin XL, the change in the IPSS was 1.3 ± 1.3 units, and during the use of 8 mg doxazosin XL, the change was 3.6 ± 2.5 units (P<0.001). The change in the Q <sub>max</sub> values for 4 and 8 mg doxazosin XL was found to be 1.6 ± 1.8 and 3.2 ± 2.7 mL/s, respectively (P=0.019). For the 4 mg doxazosin XL, the QoL values increased by 0.4 ± 0.6 units, and during the use of 8 mg doxazosin XL, the QoL values decreased by 1.8 ± 0.7 units (P<0.001).  No difference was found concerning the adverse reactions between the groups (P>0.05).  Secondary: Not reported

(2004) Doxazosin 8 mg QD  vs terazosin 10 mg QD	Men with LUTS associated with BPH	3 months	Change from baseline in IPSS and Qmax  Secondary: Not reported	The proportion of patients who showed improvement in both IPSS and Qmax were 44 and 40% of patients receiving doxazosin and Terazosin, respectively. After three months, both treatments resulted in a significantly increased Qmax (P<0.001) and a significantly decreased IPSS (P<0.01).  The number of patients who did not show improvement and had to switch to the other treatment was 19. Of these patients, two showed improvement in both IPSS and Qmax, two showed improvement in IPSS only and 15 did not show any improvement.  Secondary: Not reported
Kaplan et al. <sup>32</sup> (1997) Doxazosin 4 to 8 mg QD  vs terazosin 5 to 10 mg QD	OL, PRO  Men >80 years of age with BPH	N=36  6 months	Primary: Change from baseline in Qmax and AUA SS  Secondary: Not reported	Primary: There was significant improvement in Qmax (P<0.008) and AUA SS (P<0.01) with both treatments.  There were small, nonsignificant decreases in blood pressure with both treatments.  Secondary: Not reported
Kaplan et al. <sup>33</sup> (1995) Doxazosin 4 mg QD in the morning  vs doxazosin 4 mg QD in the evening  vs terazosin 5 mg QD in the morning	RCT  Men without HTN and symptomatic prostatism	N=43  4 to 17 months	Primary: Changes from baseline in Boyarsky symptom score, Qmax and blood pressure; adverse events  Secondary: Not reported	Primary: There were significant improvements in Boyarsky symptom scores and Qmax with all four treatments (P<0.05), with no significant differences between the treatments (P values not reported).  Adverse events were significantly decreased with evening doses (P<0.05).  Secondary: Not reported

Doxazosin 2 mg QD  vs  tamsulosin 0.2 mg QD	due to BPH		Qmax, average urinary flow rate and residual urine; safety  Secondary: Not reported	significant decrease compared to doxazosin (P=0.036).  Qmax, average urinary flow rate and residual urine significantly improved with tamsulosin only (P<0.001, P<0.001, and P<0.05, respectively).  There were no significant differences in SBP or DBP with tamsulosin; however, doxazosin resulted in significant differences in SBP (P<0.01) but not in DBP (P value not reported) at the end of the study.  Tamsulosin was well tolerated; only three patients (six percent) receiving tamsulosin reported an adverse event (dizziness), while 11 patients (22%) with doxazosin reported an adverse event (dizziness), one of whom withdrew from the trial.  Secondary: Not reported
Pompeo et al. <sup>37</sup> (2006)  Doxazosin SR 4 mg QID  vs  tamsulosin 0.4 mg QID	DB, DD, RCT  Brazilian patients with BPH	N=165  12 week	Primary: Absolute and percentage change from baseline in symptoms measured by IPSS  Secondary: Quality of life question from the IPSS and questions six and seven of the SFAQ	Primary: Doxazosin and tamsulosin improved IPSS with no significant differences between the two after 12 weeks. During weeks four to eight, tamsulosin demonstrated a slower improvement (P<0.001) in IPSS compared to doxazosin.  Secondary: The proportion of satisfied patients did not change over the course of the trial with doxazosin, while it did change significantly between weeks four and eight with tamsulosin (P=0.006); suggesting that a change for the better was observed earlier with doxazosin. After 12 weeks, the proportion of patients with little or no difficulty at ejaculation (question six of SFAQ) was significantly higher with doxazosin (P=0.019). Both treatments were well tolerated.
Cao et al. <sup>38</sup> (2016)  Doxazosin SR 4 mg QD  vs	OL, PRO, RCT  Men 50 to 80 years of age with newly diagnosed symptoms of BPH	N=192  12 weeks	Primary: IPSS  Secondary: Quality of life and Qmax	Primary: After six weeks of treatment, LUTS were improved in both groups, as seen by the change in IPSS from baseline. There was no significant difference between groups in terms of total IPSS (P=0.86). At 12 weeks, greater improvement of total IPSS was observed in the doxazosin group than in the tamsulosin group (P<0.001).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
tamsulosin 0.2 mg QD  Both groups received tolterodine ER 4 mg QD				Secondary: After six weeks treatment there was no significant difference between the groups in Qmax (P=0.19). However, quality of life was significantly improved in the doxazosin group compared to the tamsulosin group (P=0.01). At 12 weeks Qmax showed greater improvement in the doxazosin group (14.1±1.6 mL/s) than in the tamsulosin group (13.5±2.1 mL/s; P=0.03). In addition, quality of life (2.5±0.67 vs 3.1±0.7; P<0.001) of the doxazosin group was more improved (lower score represents better quality of life).
Johnson et al. <sup>39</sup> (2007)  Doxazosin 2, 4, or 8 mg QD  vs  finasteride 5 mg QD  vs  doxazosin 2, 4, or 8 mg QD plus finasteride 5 mg QD  vs  placebo	PC, RCT  Men with LUTS suggestive of BPH	N=3,047  4 years	Primary: Efficacy (mean reduction in self-reported nightly nocturia at 1 and 4 years)  Secondary: Not reported	Primary: The number of men reporting one or more episodes of nocturia who finished ≥12 months of the trial came to a total of 2,583. Mean nocturia was similar with all treatments at baseline. Mean nocturia was reduced after one year by 0.35, 0.40, 0.54 and 0.58 with placebo, finasteride, doxazosin and combination therapy, respectively. Reductions with doxazosin and combination therapy were significantly greater compared to placebo (P<0.05).  After four years, nocturia was also significantly reduced in patients receiving doxazosin and combination therapy (P<0.05 vs placebo). In men >70 years of age (n=495) all treatments significantly reduced nocturia after one year (Finasteride, 0.29; Doxazosin, 0.46 and combination therapy, 0.42) compared to placebo (0.11; P<0.05 for all).  Secondary: Not reported
Crawford et al. <sup>40</sup> (2006)  Doxazosin 4 to 8 mg QD  vs	PC, RCT  Men with LUTS suggestive of BPH	N=737  4 years	Primary: Time to overall clinical progression of BPH (either a confirmed ≥4 point increase in AUA	Primary: The rate of overall clinical progression of BPH events with placebo was 4.5 per 100 person-years, for a cumulative incidence (among men who had at least four years of follow up data) of 17%.  The risk of BPH progression was significantly greater with placebo with a baseline TPV ≥31 mL compared to a baseline TPV <31 mL (P<0.0001).

vs  doxazosin 1 to 8 mg QD plus finasteride 5 mg QD  vs  placebo				were no differences between doxazosin and combination therapy or finasteride and placebo (P values not reported).  Secondary: Doxazosin use increased the risk of asthenia, dizziness and hypotension, while impotence was reported most frequently with combination therapy.
Fwu et al. <sup>44</sup> (2013) MTOPS  Doxazosin 4 or 8 mg QD  vs  finasteride 5 mg QD  vs  doxazosin 4 or 8 mg QD plus finasteride 5 mg QD  vs  placebo	DB, MC, RCT  Patients ≥50 years of age with an AUA-SS of 8 to 30, a Qmax of 4 to 15 mL/second, and a minimum voided volume of 125 mL	N=2,872  4 years	Primary: Change in quality of life (QoL) using Benign Prostatic Hyperplasia Impact Index (BII), IPSS-QoL, and annually by the Outcomes Study Short-Form 36 (MOS-SF-36)  Secondary: Not reported	Primary: Changes in the MOS-SF-36 scores from baseline to year four of follow-up by treatment group demonstrated a statistically significant reduction (worsening) for the subscales of physical functioning, role limitations due to physical problems, bodily pain, general health perception, and vitality in all treatment groups, except bodily pain in men assigned to finasteride. No significant change was observed in mental health in any treatment group. The subscale with the greatest reduction was role limitations due to physical problems. The decrease was greatest in the placebo group (−8.83, 95% CI, −12.09 to −5.58) and least in finasteride (−6.97, −10.19 to −3.74).  The differences in changes for MOS-SF-36 subscales and summary scores between drug groups and placebo group were not statistically significant. Similarly, neither significant differences nor important effect sizes of the subscales and summary scores were observed when drug groups were compared with each other at year four.  Compared with men assigned to placebo, men assigned to doxazosin and combination experienced a statistically significant improvement in the BII at year four. Men assigned to each of the drug groups also experienced a significant improvement in the IPSS-QoL compared with those assigned to placebo.  Secondary: Not reported
Djavan et al. <sup>45</sup> (1999)	MA	N=6,333 (PC trials)	Primary: Changes from	Primary: There was no difference in efficacy among the four treatments. Alfuzosin

vs placebo				
MacDonald et al. <sup>47</sup> (2005)  Doxazosin, tamsulosin, or finasteride  vs  alfuzosin  vs  alfuzosin plus finasteride or placebo	SR (11 trials)  Men with symptomatic BPH	N=3,901  4 to 26 weeks	Primary: Change from baseline in IPSS  Secondary: Change from baseline in Qmax and urinary symptom scores, adverse effects, incidence of treatment discontinuation	Primary: In the two trials comparing alfuzosin to other $\alpha$ -adrenergic blocking agents, doxazosin demonstrated the greatest improvement in IPSS (WMD, 1.70; 95% CI, 0.76 to 1.64; P=0.05). One trial evaluated alfuzosin vs finasteride or alfuzosin plus finasteride. Alfuzosin, both alone or in combination, significantly improved LUTS compared to finasteride. When compared to placebo, alfuzosin demonstrated a greater improvement in the IPSS with a WMD of -1.8 points (95% CI, -2.49 to -1.11).  Secondary: No difference was found among $\alpha$ -adrenergic blocking agents in Qmax, while alfuzosin and tamsulosin (0.4 mg) demonstrated similar improvements in Boyarsky symptom scores.  Alfuzosin, finasteride and combination treatment all had similar changes in Qmax; however, a subgroup analysis showed greater improvement in patients with obstruction with alfuzosin and combination therapy over finasteride.  Qmax was 2.6 mL/second (10 to 54%) with alfuzosin vs 1.1 mL/second with placebo (2 to 29%). Alfuzosin demonstrated benefit over placebo in the mean urinary symptom score with a WMD of -0.90 point (95% CI, -0.94 to -0.87).  The incidences of adverse events as well as withdrawal rates were comparable among $\alpha$ -adrenergic blocking agents. Vasodilatory effects were similar with alfuzosin, finasteride and combination therapy, whereas impotence occurred significantly more often with finasteride and in combination therapy. Discontinuation of treatment was higher with alfuzosin than finasteride and lower with alfuzosin compared to combination therapy. Dizziness was the most frequently reported side effect with alfuzosin compared to placebo. Postural hypotension, syncope and somnolence were reported in less than two percent of patients treated

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				with alfuzosin, but more often than with placebo. Withdrawal rates were similar between treatments.

Talseth et al. <sup>77</sup> (1991)  Doxazosin (mean dose used: 5.2 mg QD)  vs  atenolol (mean dose used: 66.4 mg QD)	PG, RCT  Patients with mild and moderate HTN	N=164  3 years	Primary: Blood pressure, heart rate, lipids profile, calculated CHD risk using the Framingham equation  Secondary: Not reported	Primary: Both drugs produced similar reductions in blood pressure.  Atenolol produced a significant decrease in heart rate (P<0.05), while doxazosin did not change the heart rate significantly.  Doxazosin significantly reduced TG levels (P<0.001), increased HDL-C levels (P<0.001), and increased the HDL-C:TC (P<0.001) compared to atenolol.  The calculated CHD risk was significantly increased with atenolol (P<0.05) and significantly decreased with doxazosin (P<0.05) from baseline.  Secondary: Not reported
Carruthers et al. <sup>78</sup> (1993)  Doxazosin QD  vs  atenolol QD	RCT  Patients with mild to moderate systemic HTN and normal serum lipid	N=191  24 weeks	Primary: Calculated CAD risk using the Framingham formula  Secondary: Not reported	Primary: Doxazosin treatment produced a significantly greater reduction in CHD risk compared to atenolol (P=0.0074).  The relative risk of CHD was reduced to 0.92 in the atenolol group (P=0.144) and 0.74 in the doxazosin group (P=0.0001) from baseline.  Secondary: Not reported
Searle et al. <sup>79</sup> (1990)  Doxazosin 11 mg (mean dose)  vs  placebo  All patients	DB, MC, RCT  Patients with mild to moderate essential HTN	N=87  12 weeks	Primary: Changes from baseline in blood pressure, heart rate and serum lipids  Secondary: Not reported	Primary: Doxazosin was associated with significant reductions in blood pressure compared to placebo (17.0/12.3 vs 6.2/6.7 mm Hg; P<0.05). The supine blood pressure was decreased by 13.2/9.8 mm Hg with doxazosin compared to 9.2/6.0 mm Hg with placebo (P value not reported).  Only minor, nonsignificant changes in serum lipids and heart rate were observed between the two treatments (P value not reported).  Secondary: Not reported

received atenolol 100 mg/day.				
Ohta et al. <sup>80</sup> (2007)  Doxazosin 1 to 2 mg QD to BID  Treatment was added to calcium channel blockers, ARBs and ACE inhibitors.	RETRO  Patients with HTN that had poorly controlled blood pressure	N=41  3 months (mean follow up 170 days)	Primary: Changes from baseline in blood pressure and blood chemistry  Secondary: Not reported	Primary: Blood pressure decreased from 152±14/81±12 to 135±14/70±11 mm Hg after the addition of doxazosin at a mean dose of 1.5 mg/day (P<0.001).  When good SBP control was defined as <140 mm Hg, the prevalence of patients with good SBP control increased from 24 to 61% with the addition of doxazosin (P<0.01). Similarly, the prevalence of patients with good DBP control (<90 mm Hg) increased from 78 to 98% (P<0.01).  Patients whose SBP decreased >10 mm Hg (n=25) showed significantly higher baseline SBP, TC and LDL-C compared to those who showed less SBP reduction (<10 mm Hg; P<0.01).  Comparable reductions in blood pressure were obtained between obese patients (BMI ≥25, change in blood pressure at three months: -15±15/-12±9 mm Hg, n=18) and non-obese patients (-14±19/-7±8 mm Hg, n=23).  Secondary: Not reported
de Alvaro et al. <sup>81</sup> (2006) ASOCIA  Doxazosin SR 4 mg QD, increased to 8 mg/day at week 4 if required  Added to entry medication.	MC, PRO  Patients with HTN (>140/>90 mm Hg) on previous antihypertensive medication who were uncontrolled	N=3,631  16 weeks	Primary: Proportion of patients achieving goal blood pressure (<140/<90 mm Hg), adverse events  Secondary: Not reported	Primary: The proportion of patients achieving goal blood pressure after four weeks of add on therapy with doxazosin was 39% and increased to 61% after 16 weeks. SBP and DBP (mean±SEM) decreased, respectively, from 161.6±0.2/95.1±0.1 mm Hg at baseline to 142.2±0.2/84.1±0.1 mm Hg after four weeks (P<0.0001) and to 136.8±0.2/80.6±0.2 mm Hg after 16 weeks (P<0.0001).  Adverse events occurred in 108 patients (3.0%), with 57 (1.6%) related to the study treatment. In 17 patients (0.5%), serious adverse events were described, but only one was related to the study drug.  Secondary: Not reported
Os et al. <sup>82</sup> (2006)	DB, PG, RCT	N=310	Primary: Efficacy, safety	Primary: All groups had a significant decrease in blood pressure at all study visits

**IX. Cost**

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of '\$' signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 9. Relative Cost of the Alpha-Adrenergic Blocking Agents**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost
Doxazosin	extended-release tablet, tablet	Cardura <sup>®*</sup> , Cardura XL <sup>®</sup>	\$\$\$\$\$	\$
Prazosin	capsule	Minipress <sup>®*</sup>	\$\$\$\$\$	\$
Terazosin	capsule	N/A	N/A	\$

\*Generic is available in at least one dosage form or strength.

N/A=not available

**X. Conclusions**

The alpha-adrenergic blocking agents are approved for the treatment of benign prostatic hyperplasia (BPH) and hypertension.<sup>1-6</sup> All of the agents are available in a generic formulation. Treatment guidelines on the management of BPH recommend the use of an  $\alpha$ -adrenergic blocking agent or a 5 $\alpha$ -reductase inhibitor in patients with moderate-to-severe symptoms. Alpha-blockers can quickly improve symptoms and flow rate, while the 5 $\alpha$ -reductase inhibitors have the potential for long-term reduction in prostate volume.<sup>8,9</sup> Available data suggests that the combination is also effective. Clinical trials have demonstrated similar efficacy among the various  $\alpha$ -adrenergic blocking agents for the treatment of BPH.<sup>26-55</sup>

There are several national and international organizations that have published guidelines on the treatment of hypertension. Most of the guidelines do not address the use of the  $\alpha$ -adrenergic blocking agents.<sup>17-25</sup> Thiazide-type diuretics are frequently recommended as initial therapy in patients with uncomplicated hypertension. According to the National Heart, Lung, and Blood Institute's Eighth Report of The Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 8), thiazide-type diuretics should be utilized first-line for most patients with hypertension, either alone or in combination with another antihypertensive from a different medication class (e.g., ACE inhibitors, ARBs,  $\beta$ -blockers, calcium channel blockers).<sup>17</sup> Several guidelines consistently recommend that the selection of an antihypertensive agent be based on compelling indications for use.<sup>17-22</sup> Most patients will require more than one antihypertensive medication to achieve blood pressure goals.<sup>17-23</sup>

Several clinical trials have demonstrated that the  $\alpha$ -adrenergic blocking agents effectively lower blood pressure when administered as monotherapy or in combination with other antihypertensive agents. Comparative studies have demonstrated similar efficacy when the  $\alpha$ -blockers were directly compared to each other, as well as when they were compared to ACE inhibitors,  $\beta$ -blockers, calcium-channel blocking agents and thiazide-type diuretics.<sup>56-88</sup> The ALLHAT trial evaluated the effects of doxazosin on cardiovascular morbidity and mortality. Treatment with doxazosin increased the risk of stroke and cardiovascular events; however, it provided other benefits including improvements in insulin resistance and lipid parameters.<sup>89-92</sup>

There is insufficient evidence to support that one brand alpha-adrenergic blocking agent is safer or more efficacious than another. Formulations without a generic alternative should be managed through the medical justification portion of the prior authorization process.

Therefore, all brand alpha-adrenergic blocking agents within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

## **XI. Recommendations**

No brand alpha-adrenergic blocking agent is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

**Alabama Medicaid Agency  
Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Beta-Adrenergic Blocking Agents  
AHFS Class 242400  
May 4, 2022**

**I. Overview**

The beta-adrenergic blocking agents ( $\beta$ -blockers) are approved for the treatment of angina, arrhythmias, essential tremor, heart failure, hypertension, hypertrophic aortic stenosis, migraine prophylaxis, myocardial infarction, and pheochromocytoma.<sup>1-22</sup> Additionally, propranolol is the first agent Food and Drug Administration-approved for the treatment of proliferating infantile hemangioma requiring systemic therapy.<sup>12,24</sup> The  $\beta$ -blockers differ with regards to their adrenergic-receptor blocking, membrane stabilizing and intrinsic sympathomimetic activities, as well as lipophilicity.<sup>1-23</sup> There are at least three distinct types of  $\beta$  receptors distributed throughout the body ( $\beta_1$ ,  $\beta_2$ , and  $\beta_3$ ).  $\beta_1$  receptors are located predominantly in the heart and kidneys.  $\beta_2$  receptors are located in the lungs, gastrointestinal tract, liver, uterus, vascular smooth muscle, and skeletal muscle.  $\beta_3$ -receptors are located in fat cells.  $\beta$ -blockers primarily exert their effects through a blockade of  $\beta_1$  and  $\beta_2$  receptor subtypes. Agents that have a greater affinity for  $\beta_1$  receptors are considered to be cardioselective. These agents may be safer in patients with asthma, chronic obstructive pulmonary disease, and peripheral vascular disease because they produce less inhibition of  $\beta_2$  receptors, which mediate vasoconstriction and bronchospasm. Cardioselectivity is dose dependent; therefore,  $\beta_2$  blockade can occur at higher doses with these agents.<sup>23,25</sup> Carvedilol and labetalol also block  $\alpha$ -adrenergic receptors, which would be expected to reduce peripheral vascular resistance to a greater extent than other  $\beta$ -blockers.<sup>23,25</sup>

The  $\beta$ -blockers are available as single entity agents, as well as fixed-dose combination products. Each of the combination products contains a thiazide-type diuretic. The thiazide-type diuretics inhibit the reabsorption of sodium and chloride in the cortical thick ascending limb of the loop of Henle and the early distal tubules. This action leads to an increase in the urinary excretion of sodium and chloride.<sup>1,2,17-22</sup>

The  $\beta$ -adrenergic blocking agents that are included in this review are listed in Table 1 and comparative information on cardioselectivity is highlighted in Table 2. This review encompasses all dosage forms and strengths. All of the agents are available in a generic formulation, with the exception of penbutolol. This class was last reviewed in February 2020.

**Table 1. Beta-Adrenergic Blocking Agents Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
<b>Single Entity Agents</b>			
Acebutolol	capsule	N/A	acebutolol
Atenolol	tablet	Tenormin <sup>®*</sup>	atenolol
Betaxolol	tablet	N/A	betaxolol
Bisoprolol	tablet	N/A	bisoprolol
Carvedilol	extended-release capsule, tablet	Coreg <sup>®*</sup> , Coreg CR <sup>®*</sup>	carvedilol
Esmolol	injection <sup>^</sup>	Brevibloc <sup>®*</sup>	none
Labetalol	injection <sup>^</sup> , tablet	N/A	labetalol
Metoprolol	extended-release capsule, extended-release tablet, injection, tablet	Kaspargo Sprinkle <sup>®</sup> , Lopressor <sup>®*</sup> , Toprol-XL <sup>®*</sup>	metoprolol
Nadolol	tablet	Corgard <sup>®*</sup>	nadolol
Nebivolol	tablet	Bystolic <sup>®*</sup>	Bystolic <sup>®</sup> , nebivolol
Penbutolol	tablet	Levatol <sup>®†</sup>	none
Pindolol	tablet	N/A	pindolol
Propranolol	extended-release capsule, injection, solution, tablet	Hemangeol <sup>®</sup> , Inderal LA <sup>®*</sup> , Inderal XL <sup>®</sup> , InnoPran XL <sup>®</sup>	propranolol
Sotalol	tablet, solution	Betapace <sup>®*</sup> , Betapace	sotalol

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
		AF <sup>®*</sup> , Sotylize <sup>®</sup>	
Timolol	tablet	N/A	timolol
<b>Combination Products</b>			
Atenolol and chlorthalidone	tablet	Tenoretic <sup>®*</sup>	atenolol and chlorthalidone
Bisoprolol and hydrochlorothiazide	tablet	Ziac <sup>®*</sup>	bisoprolol and hydrochlorothiazide
Metoprolol and hydrochlorothiazide	tablet	N/A	metoprolol and hydrochlorothiazide
Nadolol and bendroflumethiazide	tablet	N/A	nadolol and bendroflumethiazide

\*Generic is available in at least one dosage form or strength.

^Product is primarily administered in an institution.

†Product was discontinued by manufacturer, but remains active in pharmacy system.

PDL=Preferred Drug List

N/A=Not available

**Table 2. Selected Pharmacologic Properties of the Beta-Adrenergic Blocking Agents<sup>1-22</sup>**

Generic Name(s)	Adrenergic-Receptor Blocking Activity	Membrane Stabilizing Activity	Intrinsic Sympathomimetic Activity

Timolol	$\beta_1 - \beta_2$	0	0

0=none; +=low; ++=moderate; +++ =high

\*Inhibits  $\beta_2$  receptors (bronchial and vascular) at higher doses.

†Detectable only at doses much greater than required for  $\beta$  blockade.

## II. Evidence-Based Medicine and Current Treatment Guidelines

Current treatment guidelines that incorporate the use of the  $\beta$ -adrenergic blocking agents are summarized in Table 3.

**Table 3. Treatment Guidelines Using the Beta-Adrenergic Blocking Agents**

Clinical Guideline	Recommendations
European Society of Cardiology: <b>Guidelines for the Diagnosis and Management of Chronic Coronary Syndromes (2019)<sup>26</sup></b>	<p><b>Pharmacological management of stable coronary artery disease (CAD) patients</b></p> <ul style="list-style-type: none"> <li>The two aims of the pharmacological management of stable CAD patients are to obtain relief of symptoms and to prevent CV events.</li> <li>Optimal medical treatment indicates at least one drug for angina/ischaemia relief plus drugs for event prevention.</li> <li>It is recommended to educate patients about the disease, risk factors and treatment strategy.</li> <li>It is indicated to review the patient's response soon after starting therapy.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Concomitant use of a proton pump inhibitor is recommended in patients receiving aspirin monotherapy, DAPT, or DOAC monotherapy who are at high risk of gastrointestinal bleeding.</li> <li>• Lipid-lowering drugs: if goals are not met on maximum tolerated dose of a statin, consideration of combination therapy with ezetimibe or a PCSK9 inhibitor is recommended</li> <li>• ACE inhibitors should be considered in patients at a very high risk of cardiovascular adverse events</li> <li>• Angina/ischemia relief: <ul style="list-style-type: none"> <li>○ Short-acting nitrates are recommended.</li> <li>○ First-line treatment is indicated with <math>\beta</math>-blockers and/or calcium channel blockers to control heart rate and symptoms.</li> <li>○ Long-acting nitrates should be considered as a second-line treatment option when initial therapy with a beta-blocker and/or a non-DHP-calcium channel blocker is contraindicated, poorly tolerated, or inadequate in controlling angina symptoms</li> <li>○ Nicorandil, ranolazine, ivabradine, or trimetazidine should be considered as a second-line treatment to reduce angina frequency and improve exercise tolerance in subjects who cannot tolerate, have contraindications to, or whose symptoms are not adequately controlled by beta-blockers, CCBs, and long-acting nitrates.</li> <li>○ According to comorbidities/tolerance, it is indicated to use second-line therapies as first-line treatment in selected patients.</li> <li>○ In asymptomatic patients with large areas of ischaemia (&gt;10%) <math>\beta</math>-blockers should be considered.</li> <li>○ In patients with vasospastic angina, calcium channel blockers and nitrates should be considered and beta-blockers avoided.</li> </ul> </li> <li>• Event prevention: <ul style="list-style-type: none"> <li>○ Low-dose aspirin daily is recommended in all stable CAD patients.</li> <li>○ Clopidogrel is indicated as an alternative in case of aspirin intolerance.</li> <li>○ Statins are recommended in all stable CAD patients.</li> <li>○ It is recommended to use ACE inhibitors (or ARBs) if presence of other conditions (e.g., heart failure, hypertension or diabetes).</li> </ul> </li> </ul> <p><u>Treatment in patients with microvascular angina</u></p> <ul style="list-style-type: none"> <li>• It is recommended that all patients receive secondary prevention medications including aspirin and statins.</li> <li>• <math>\beta</math>-blockers are recommended as a first-line treatment.</li> <li>• Calcium antagonists are recommended if <math>\beta</math>-blockers do not achieve sufficient symptomatic benefit or are not tolerated.</li> <li>• ACE inhibitors or nicorandil may be considered in patients with refractory symptoms.</li> <li>• Xanthine derivatives or nonpharmacological treatments such as neurostimulatory techniques may be considered in patients with symptoms refractory to the above listed drugs.</li> </ul> <p><u>Stenting and peri-procedural antiplatelet strategies in stable CAD patients</u></p> <ul style="list-style-type: none"> <li>• Drug-eluting stent (DES) is recommended in stable CAD patients undergoing stenting if there is no contraindication to prolonged dual antiplatelet therapy (DAPT).</li> <li>• Aspirin is recommended for elective stenting.</li> <li>• Clopidogrel is recommended for elective stenting.</li> <li>• Prasugrel or ticagrelor should be considered in patients with stent thrombosis on clopidogrel without treatment interruption.</li> <li>• GP IIb/IIIa antagonists should be considered for bailout situation only.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Platelet function testing or genetic testing may be considered in specific or high risk situations (e.g., prior history of stent thrombosis; compliance issue; suspicion of resistance; high bleeding risk) if results may change the treatment strategy.</li> <li>• Prasugrel or ticagrelor may be considered in specific high-risk situations of elective stenting (e.g., left main stenting, high risk of stent thrombosis, diabetes).</li> <li>• Pretreatment with clopidogrel (when coronary anatomy is not known) is not recommended.</li> <li>• Routine platelet function testing (clopidogrel and aspirin) to adjust antiplatelet therapy before or after elective stenting is not recommended.</li> <li>• Prasugrel or ticagrelor is not recommended in low-risk elective stenting.</li> <li>• After uncomplicated PCI, early cessation (<math>\leq 1</math> week) of aspirin, and continuation of dual therapy with oral anticoagulation therapy and clopidogrel should be considered if the risk of stent thrombosis is low</li> <li>• Triple therapy with aspirin, clopidogrel, and a DOAC for <math>\geq 1</math> month should be considered when the risk of stent thrombosis outweighs the bleeding risk, with a total of no more than six months</li> </ul> <p><u>Follow-up of revascularized stable coronary artery disease patients</u></p> <ul style="list-style-type: none"> <li>• It is recommended that all revascularized patients receive a secondary prevention and be scheduled for follow-up visit.</li> <li>• It is recommended to instruct patients before discharge about return to work and resumption of full activities. Patients have to be advised to seek immediate medical contact if symptoms (re-) occur.</li> <li>• Single antiplatelet therapy, usually aspirin, is recommended indefinitely.</li> <li>• DAPT is indicated after bare metal stent (BMS) for at least one month.</li> <li>• DAPT is indicated for six to 12 months after second generation DES.</li> <li>• DAPT may be used for more than one year in patients at high ischemic risk (e.g., stent thrombosis, recurrent acute coronary syndrome on DAPT, post MI/diffuse CAD) and low bleeding risk.</li> <li>• DAPT for one to three months may be used after DES implantation in patients at high bleeding risk or with undeferrable surgery or concomitant anticoagulant treatment.</li> </ul> <p><u>Antithrombotic therapy in patients with chronic coronary syndrome:</u></p> <ul style="list-style-type: none"> <li>• Addition of a second antithrombotic drug to aspirin for long-term secondary prevention should be considered in patients with at least a moderately increased risk of ischemic events and without high bleeding risk</li> <li>• When oral anticoagulation is initiated in patients with AF, a DOAC is recommended in preference to VKA therapy.</li> </ul>
<p>American College of Physicians/ American College of Cardiology Foundation/ American Heart Association/ American Association for Thoracic Surgery/ Preventive Cardiovascular Nurses Association/ Society of Thoracic Surgeons:  <b>Management of</b></p>	<p><u>Medical therapy to prevent myocardial infarction (MI) and death in patients with stable ischemic heart disease (IHD)</u></p> <ul style="list-style-type: none"> <li>• Aspirin 75 to 162 mg daily should be continued indefinitely in the absence of contraindications.</li> <li>• Treatment with clopidogrel is a reasonable option when aspirin is contraindicated.</li> <li>• Dipyridamole should not be used as antiplatelet therapy.</li> <li>• Beta-blocker therapy should be initiated and continued for three years in all patients with normal left ventricular (LV) function following MI or acute coronary syndromes.</li> <li>• Metoprolol succinate, carvedilol, or bisoprolol should be used for all patients with systolic LV dysfunction (ejection fraction <math>\leq 40\%</math>) with heart failure or prior MI, unless contraindicated.</li> <li>• ACE inhibitors should be prescribed in all patients with stable IHD who also have hypertension, diabetes, LV systolic dysfunction (ejection fraction <math>\leq 40\%</math>), and/or chronic kidney disease, unless contraindicated.</li> <li>• Angiotensin-receptor blockers (ARBs) are recommended for patients with stable</li> </ul>

Clinical Guideline	Recommendations
<p><b>Stable Ischemic Heart Disease (2012)</b><sup>27</sup></p>	<p>IHD who have hypertension, diabetes, LV systolic dysfunction, or chronic kidney disease and have indications for, but are intolerant of, ACE inhibitors.</p> <ul style="list-style-type: none"> <li>• Patients should receive an annual influenza vaccine.</li> </ul> <p><u>Medical therapy for relief of symptoms in patients with stable IHD</u></p> <ul style="list-style-type: none"> <li>• Beta-blockers are recommended as initial therapy for relief of symptoms.</li> <li>• Calcium channel blockers or long-acting nitrates should be prescribed for relief of symptoms when <math>\beta</math>-blockers are contraindicated or cause unacceptable side effects.</li> <li>• Calcium channel blockers or long-acting nitrates, in combination with <math>\beta</math>-blockers, should be prescribed for relief of symptoms when initial treatment with <math>\beta</math>-blockers is unsuccessful.</li> <li>• Nitroglycerin or nitroglycerin spray should be used for immediate relief of angina.</li> <li>• Ranolazine is a fourth-line agent reserved for patients who have contraindications to, do not respond to, or cannot tolerate <math>\beta</math>-blockers, calcium-channel blockers, or long-acting nitrates.</li> </ul>
<p>American College of Cardiology Foundation/ American Heart Association: <b>2014 American Heart Association/ American College of Cardiology Foundation Guideline for the Management of Patients With Non-ST-Elevation Acute Coronary Syndromes (2014)</b><sup>28</sup></p>	<p><u>Early hospital care- standard medical therapies</u></p> <ul style="list-style-type: none"> <li>• Supplemental oxygen should be administered to patients with non-ST-elevation acute coronary syndrome (NSTEMI-ACS) with arterial oxygen saturation &lt;90%, respiratory distress, or other high risk features of hypoxemia.</li> <li>• Anti-ischemic and analgesic medications <ul style="list-style-type: none"> <li>○ Nitrates <ul style="list-style-type: none"> <li>▪ Patients with NSTEMI-ACS with continuing ischemic pain should receive sublingual nitroglycerin (0.3 to 0.4 mg) every 5 minutes for up to three doses, after which an assessment should be made about the need for intravenous nitroglycerin.</li> <li>▪ Intravenous nitroglycerin is indicated for patients with NSTEMI-ACS for the treatment of persistent ischemia, heart failure, or hypertension.</li> <li>▪ Nitrates should not be administered to patients who recently received a phosphodiesterase inhibitor, especially within 24 hours of sildenafil or vardenafil, or within 48 hours of tadalafil.</li> </ul> </li> <li>○ Analgesic therapy <ul style="list-style-type: none"> <li>▪ In the absence of contraindications, it may be reasonable to administer morphine sulphate intravenously to patients with NSTEMI-ACS if there is continued ischemic chest pain despite treatment with maximally tolerated anti-ischemic medications.</li> <li>▪ Nonsteroidal anti-inflammatory drugs (NSAIDs) (except aspirin) should not be initiated and should be discontinued during hospitalization due to the increased risk of major adverse cardiac event associated with their use</li> </ul> </li> <li>○ Beta-adrenergic blockers <ul style="list-style-type: none"> <li>▪ Oral <math>\beta</math>-blocker therapy should be initiated within the first 24 hours in patients who do not have any of the following: 1) signs of HF, 2) evidence of low-output state, 3) increased risk for cardiogenic shock, or 4) other contraindications to <math>\beta</math>blockade (e.g., PR interval &gt;0.24 second, second- or third-degree heart block without a cardiac pacemaker, active asthma, or reactive airway disease)</li> <li>▪ In patients with concomitant NSTEMI-ACS, stabilized heart failure, and reduced systolic function, it is recommended to continue <math>\beta</math>-blocker therapy with one of the three drugs proven to reduce mortality in patients with heart failure: sustained-release metoprolol succinate, carvedilol, or bisoprolol.</li> <li>▪ Patients with documented contraindications to <math>\beta</math>-blockers in the first 24 hours should be re-evaluated to determine subsequent eligibility.</li> </ul> </li> <li>○ Calcium channel blockers (CCBs) <ul style="list-style-type: none"> <li>▪ In patients with NSTEMI-ACS, continuing or frequently recurring ischemia, and a contraindication to <math>\beta</math>-blockers, a nondihydropyridine</li> </ul> </li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>CCB (e.g., verapamil or diltiazem) should be given as initial therapy in the absence of clinically significant LV dysfunction, increased risk for cardiogenic shock, PR interval &gt;0.24 seconds, or second or third degree atrioventricular block without a cardiac pacemaker.</p> <ul style="list-style-type: none"> <li>▪ Oral nondihydropyridine calcium antagonists are recommended in patients with NSTEMI-ACS who have recurrent ischemia in the absence of contraindications, after appropriate use of <math>\beta</math>-blockers and nitrates.</li> <li>▪ CCBs are recommended for ischemic symptoms when <math>\beta</math>-blockers are not successful, are contraindicated, or cause unacceptable side effects.</li> <li>▪ Long-acting CCBs and nitrates are recommended in patients with coronary artery spasm.</li> <li>▪ Immediate-release nifedipine should not be administered to patients with NSTEMI-ACS in the absence of <math>\beta</math>-blocker therapy.</li> </ul> <ul style="list-style-type: none"> <li>○ Other anti-ischemic interventions <ul style="list-style-type: none"> <li>▪ Ranolazine is currently indicated for treatment of chronic angina; however, it may also improve outcomes in NSTEMI-ACS patients due to a reduction in recurrent ischemia.</li> </ul> </li> <li>○ Cholesterol management <ul style="list-style-type: none"> <li>▪ High-intensity statin therapy should be initiated or continued in all patients with NSTEMI-ACS and no contraindications to its use. Treatment with statins reduces the rate of recurrent MI, coronary heart disease mortality, need for myocardial revascularization, and stroke.</li> <li>▪ It is reasonable to obtain a fasting lipid profile in patients with NSTEMI-ACS, preferably within 24 hours of presentation.</li> </ul> </li> </ul> <ul style="list-style-type: none"> <li>• Inhibitors of renin-angiotensin-aldosterone system <ul style="list-style-type: none"> <li>○ ACE inhibitors should be started and continued indefinitely in all patients with LVEF &lt;0.40 and in those with hypertension, diabetes mellitus, or stable CKD, unless contraindicated.</li> <li>○ ARBs are recommended in patients with heart failure or myocardial infarction with LVEF &lt;0.40 who are ACE inhibitor intolerant.</li> <li>○ Aldosterone-blockade is recommended in patients post-MI without significant renal dysfunction (creatinine &gt;2.5 mg/dL in men or &gt;2.0 mg/dL in women) or hyperkalemia (K &gt;5.0 mEq/L) who are receiving therapeutic doses of ACE inhibitor and <math>\beta</math>-blocker and have a LVEF &lt;0.40, diabetes mellitus, or heart failure.</li> </ul> </li> <li>• Initial antiplatelet/anticoagulant therapy in patients with definite or likely NSTEMI-ACS treated with an initial invasive or ischemia-guided strategy <ul style="list-style-type: none"> <li>○ Non-enteric coated, chewable aspirin (162 to 325 mg) should be given to all patients with NSTEMI-ACS without contraindications as soon as possible after presentation, and a maintenance dose of aspirin (81 to 162 mg/day) should be continued indefinitely.</li> <li>○ In patients who are unable to take aspirin because of hypersensitivity or major gastrointestinal intolerance, a loading dose of clopidogrel followed by a daily maintenance dose should be administered.</li> <li>○ A P2Y<sub>12</sub> receptor inhibitor (clopidogrel or ticagrelor) in addition to aspirin should be administered for up to 12 months to all patients with NSTEMI-ACS without contraindications who are treated with an early invasive or ischemia-guided strategy. Options include: <ul style="list-style-type: none"> <li>▪ Clopidogrel: 300 or 600 mg loading dose, then 75 mg daily.</li> <li>▪ Ticagrelor: 180 mg loading dose, then 90 mg twice daily.</li> <li>▪ It is reasonable to use ticagrelor in preference to clopidogrel for P2Y<sub>12</sub> treatment in patients with NSTEMI-ACS who undergo an early invasive or ischemia-guided strategy.</li> <li>▪ In patients with NSTEMI-ACS treated with an early invasive strategy and dual antiplatelet therapy (DAPT) with intermediate/high-risk features (e.g., positive troponin), a GP IIb/IIIa inhibitor may be considered as</li> </ul> </li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>part of initial antiplatelet therapy. Preferred options are eptifibatide or tirofiban.</p> <p><u>Percutaneous coronary intervention (PCI)- Antiplatelet and anticoagulant therapy</u></p> <ul style="list-style-type: none"> <li>• Antiplatelet agents <ul style="list-style-type: none"> <li>○ Patients already taking daily aspirin before PCI should take 81 to 325 mg non-enteric coated aspirin before PCI</li> <li>○ Patients not on aspirin therapy should be given non-enteric coated aspirin 325 mg as soon as possible before PCI.</li> <li>○ After PCI, aspirin should be continued indefinitely.</li> <li>○ A loading dose of a P2Y<sub>12</sub> inhibitor should be given before the procedure in patients undergoing PCI with stenting. Options include clopidogrel 600 mg, prasugrel 60 mg, or ticagrelor 180 mg.</li> <li>○ In patients with NSTEMI-ACS and high-risk features (e.g., elevated troponin) not adequately pretreated with clopidogrel or ticagrelor, it is useful to administer a GP IIb/IIIa inhibitor (abciximab, double-bolus eptifibatide, or high-dose bolus tirofiban) at the time of PCI.</li> <li>○ In patients receiving a stent (bare metal or drug eluting) during PCI, P2Y<sub>12</sub> inhibitor therapy should be given for at least 12 months. Options include clopidogrel 75 mg daily, prasugrel 10 mg daily, or ticagrelor 90 mg twice daily.</li> </ul> </li> <li>• Anticoagulant therapy <ul style="list-style-type: none"> <li>○ An anticoagulant should be administered to patients with NSTEMI-ACS undergoing PCI to reduce the risk of intracoronary and catheter thrombus formation.</li> <li>○ Intravenous unfractionated heparin (UFH) is useful in patients with NSTEMI-ACS undergoing PCI.</li> <li>○ Bivalirudin is useful as an anticoagulant with or without prior treatment with UFH.</li> <li>○ An additional dose of 0.3 mg/kg intravenous enoxaparin should be administered at the time of PCI to patients with NSTEMI-ACS who have received fewer than two therapeutic subcutaneous doses or received the last subcutaneous enoxaparin dose eight to 12 hours before PCI.</li> <li>○ If PCI is performed while the patient is on fondaparinux, an additional 85 IU/kg of UFH should be given intravenously immediately before PCI because of the risk of catheter thrombosis (60 IU/kg IV if a GP IIb/IIIa inhibitor used with UFH dosing based on the target-activated clotting time).</li> <li>○ Anticoagulant therapy should be discontinued after PCI unless there is a compelling reason to continue.</li> </ul> </li> <li>• Timing of coronary artery bypass grafting (CABG) in relation to use of antiplatelet agents <ul style="list-style-type: none"> <li>○ Non-enteric coated aspirin (81 to 325 mg daily) should be administered preoperatively to patients undergoing CABG.</li> <li>○ In patients referred for elective CABG, clopidogrel and ticagrelor should be discontinued for at least five days before surgery and prasugrel for at least seven days before surgery.</li> <li>○ In patients referred for urgent CABG, clopidogrel and ticagrelor should be discontinued for at least 24 hours to reduce major bleeding.</li> <li>○ In patients referred for CABG, short-acting intravenous GP IIb/IIIa inhibitors (eptifibatide or tirofiban) should be discontinued for at least 2 to 4 hours before surgery and abciximab for at least 12 hours before to limit blood loss and transfusion.</li> </ul> </li> </ul> <p><u>Late hospital care, hospital discharge, and posthospital discharge care</u></p> <ul style="list-style-type: none"> <li>• Medications at discharge <ul style="list-style-type: none"> <li>○ Medications required in the hospital to control ischemia should be continued</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>after hospital discharge in patients with NSTEMI-ACS who do not undergo coronary revascularization, patients with incomplete or unsuccessful revascularization, and patients with recurrent symptoms after revascularization. Titration of the doses may be required.</p> <ul style="list-style-type: none"> <li>○ All patients who are post-NSTEMI-ACS should be given sublingual or spray nitroglycerin with verbal and written instructions for its use.</li> <li>○ Before hospital discharge, patients with NSTEMI-ACS should be informed about symptoms of worsening myocardial ischemia and MI and should be given verbal and written instructions about how and when to seek emergency care for such symptoms.</li> <li>○ Before hospital discharge, patients who are post-NSTEMI-ACS and/or designated responsible caregivers should be provided with easily understood and culturally sensitive verbal and written instructions about medication type, purpose, dose, frequency, side effects, and duration of use.</li> <li>○ For patients who are post-NSTEMI-ACS and have initial angina lasting more than one minute, nitroglycerin (one dose sublingual or spray) is recommended if angina does not subside within three to five minutes; call 9-1-1 immediately to access emergency medical services.</li> <li>○ If the pattern or severity of angina changes, suggesting worsening myocardial ischemia (e.g., pain is more frequent or severe or is precipitated by less effort or occurs at rest), patients should contact their clinician without delay to assess the need for additional treatment or testing.</li> <li>○ Before discharge, patients should be educated about modification of cardiovascular risk factors.</li> </ul> <ul style="list-style-type: none"> <li>● Late hospital and post-hospital oral antiplatelet therapy <ul style="list-style-type: none"> <li>○ Aspirin should be continued indefinitely. The dose should be 81 mg daily in patients treated with ticagrelor and 81 to 325 mg daily in all other patients.</li> <li>○ In addition to aspirin, a P2Y<sub>12</sub> inhibitor (either clopidogrel or ticagrelor) should be continued for up to 12 months in all patients with NSTEMI-ACS without contraindications who are treated with an ischemia-guided strategy.</li> <li>○ In patients receiving a stent (bare-metal stent or DES) during PCI for NSTEMI-ACS, P2Y<sub>12</sub> inhibitor therapy should be given for at least 12 months.</li> </ul> </li> <li>● Combined oral anticoagulant therapy and antiplatelet therapy in patients with NSTEMI-ACS <ul style="list-style-type: none"> <li>○ The duration of triple antithrombotic therapy with a vitamin K antagonist, aspirin, and a P2Y<sub>12</sub> receptor inhibitor in patients with NSTEMI-ACS should be minimized to the extent possible to limit the risk of bleeding.</li> <li>○ Proton pump inhibitors should be prescribed in patients with NSTEMI-ACS with a history of gastrointestinal bleeding who require triple antithrombotic therapy with a vitamin K antagonist, aspirin, and a P2Y<sub>12</sub> receptor inhibitor.</li> </ul> </li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Management of Acute Coronary Syndromes in Patients Presenting without Persistent ST-Segment Elevation (2020)</b><sup>29</sup></p>	<p><u>Pharmacological treatment of ischemia</u></p> <ul style="list-style-type: none"> <li>● Sublingual or intravenous nitrates and early initiation of <math>\beta</math>-blocker treatment is recommended in patients with ongoing ischemic symptoms and without contraindications.</li> <li>● Continuation of chronic <math>\beta</math>-blocker therapy is recommended unless the patient is in overt heart failure</li> <li>● Sublingual or intravenous nitrates are recommended to relieve angina; intravenous treatment is recommended in patients with recurrent angina, uncontrolled hypertension, or signs of heart failure.</li> <li>● In patients with suspected/confirmed vasospastic angina, calcium channel blockers, and nitrates should be considered and <math>\beta</math>-blockers avoided.</li> </ul> <p><u>Recommendations for platelet inhibition in non-ST-elevation acute coronary syndromes</u></p> <ul style="list-style-type: none"> <li>● Aspirin is recommended for all patients without contraindications at an initial oral</li> </ul>

Clinical Guideline	Recommendations
	<p>loading dose of 150 to 300 mg (in aspirin-naïve patients) and a maintenance dose of 75 to 100 mg/day long-term regardless of treatment strategy.</p> <ul style="list-style-type: none"> <li>• A P2Y<sub>12</sub> inhibitor is recommended, in addition to aspirin, for 12 months unless there are contraindications such as excessive risks of bleeds. <ul style="list-style-type: none"> <li>○ Ticagrelor (180 mg loading dose, 90 mg twice daily) is recommended, in the absence of contraindication, for all patients at moderate-to-high risk of ischemic events (e.g., elevated cardiac troponins), regardless of initial treatment strategy and including those pretreated with clopidogrel (which should be discontinued when ticagrelor is started).</li> <li>○ Prasugrel (60 mg loading dose, 10 mg daily dose) is recommended in patients who are proceeding to PCI if no contraindication. Prasugrel should be considered in preference to ticagrelor in NSTEMI-ACS patients who proceed to PCI.</li> <li>○ Clopidogrel (300 to 600 mg loading dose, 75 mg daily dose) is recommended for patients who cannot receive ticagrelor or prasugrel or who require oral anticoagulation.</li> </ul> </li> <li>• P2Y<sub>12</sub> inhibitor administration for a shorter duration of three to six months after DES implantation may be considered in patients deemed at high bleeding risk.</li> <li>• Pre-treatment with a P2Y<sub>12</sub> inhibitor may be considered in patients with NSTEMI-ACS who are not planned to undergo an early invasive strategy.</li> <li>• It is not recommended to administer routine pre-treatment with a P2Y<sub>12</sub> inhibitor in patients in whom coronary anatomy is not known.</li> <li>• It is not recommended to administer prasugrel in patients whom coronary anatomy is not known.</li> <li>• GPIIb/IIIa inhibitors during PCI should be considered for bailout situations or thrombotic complications.</li> <li>• Cangrelor may be considered in P2Y<sub>12</sub> inhibitor-naïve patients undergoing PCI.</li> <li>• It is not recommended to administer GPIIb/IIIa inhibitors in patients whom coronary anatomy is not known.</li> <li>• P2Y<sub>12</sub> inhibitor administration in addition to aspirin beyond one year may be considered after careful assessment of the ischemic and bleeding risks of the patient.</li> </ul> <p><u>Recommendations for anticoagulation in non-ST-elevation acute coronary syndromes</u></p> <ul style="list-style-type: none"> <li>• Parenteral anticoagulation is recommended at the time of diagnosis according to both ischemic and bleeding risks.</li> <li>• Fondaparinux is recommended as having the most favorable efficacy-safety profile regardless of the management strategy.</li> <li>• Bivalirudin is recommended as an alternative to UFH plus GPIIb/IIIa inhibitors during PCI.</li> <li>• UFH is recommended in patients undergoing PCI who did not receive any anticoagulant.</li> <li>• In patients on fondaparinux undergoing PCI, a single intravenous bolus of UFH is recommended during the procedure.</li> <li>• Enoxaparin or UFH are recommended when fondaparinux is not available.</li> <li>• Enoxaparin should be considered as an anticoagulant for PCI in patients pretreated for PCI with subcutaneous enoxaparin.</li> <li>• Additional activated clotting time-guided intravenous boluses of UFH during PCI may be considered following initial UFH treatment.</li> <li>• Discontinuation of anticoagulation should be considered after PCI, unless otherwise indicated.</li> <li>• Crossover between UFH and LMWH is not recommended.</li> <li>• In NSTEMI patients with no prior stroke/TIA and at high ischemic risk as well as low bleeding risk receiving aspirin and clopidogrel, low-dose rivaroxaban (2.5 mg twice daily for approximately one year) may be considered after discontinuation of</li> </ul>

Clinical Guideline	Recommendations

Clinical Guideline	Recommendations
<p>American College of Cardiology/ American Heart Association: <b>Guideline for the Management of ST-Elevation Myocardial Infarction (2013)</b><sup>30</sup></p>	<p><u>Routine medical therapies: <math>\beta</math>-blockers</u></p> <ul style="list-style-type: none"> <li>• Oral <math>\beta</math>-blockers should be initiated within the first 24 hours in patients with an ST-segment elevation myocardial infarction (STEMI) who do not have any of the following: 1) signs of heart failure, 2) evidence of a low-output state, 3) increased risk of cardiogenic shock, 4) other contraindications to use of oral <math>\beta</math>-blockers (e.g., PR interval &gt;24 seconds, second or third degree heart block, active asthma, reactive airway disease).</li> <li>• <math>\beta</math>-blockers should be continued during and after hospitalization for all patients with STEMI and with no contraindications to their use.</li> <li>• Patients with initial contraindications to the use of <math>\beta</math>-blockers in the first 24 hours after STEMI should be re-evaluated to determine their subsequent eligibility.</li> <li>• It is reasonable to administer intravenous <math>\beta</math>-blockers at the time of presentation to patients with STEMI and no contraindications to their use who are hypertensive or have ongoing ischemia.</li> </ul> <p><u>Routine medical therapies: Renin-Angiotensin-Aldosterone System Inhibitors</u></p> <ul style="list-style-type: none"> <li>• An angiotensin-converting enzyme (ACE) inhibitor should be administered within the first 24 hours to all patients with STEMI with anterior location, HF, or ejection fraction (EF) <math>\leq</math>40%, unless contraindicated.</li> <li>• An angiotensin receptor blocker (ARB) should be given to patients with STEMI who have indications for but are intolerant of ACE inhibitors.</li> <li>• An aldosterone antagonist should be given to patients with STEMI and no contraindications who are already receiving an ACE inhibitor and <math>\beta</math>-blocker and who have an EF <math>\leq</math>40% and either symptomatic heart failure or diabetes.</li> </ul> <p><u>Routine medical therapies: Lipid management</u></p> <ul style="list-style-type: none"> <li>• High-intensity statin therapy should be initiated or continued in all patients with STEMI and no contraindications to its use.</li> <li>• It is reasonable to obtain a fasting lipid profile in patients with STEMI, preferably within 24 hours of presentation.</li> </ul>
<p>European Society of Cardiology: <b>Management of Acute Myocardial Infarction in Patients Presenting with ST-segment Elevation (2017)</b><sup>31</sup></p>	<p><u>Routine therapies in the acute, subacute and long term phase of STEMI</u></p> <ul style="list-style-type: none"> <li>• Antiplatelet therapy with low dose aspirin (75 to 100 mg) is indicated indefinitely after STEMI.</li> <li>• Dual antiplatelet therapy with a combination of aspirin and prasugrel or aspirin and ticagrelor is recommended for 12 months after percutaneous coronary intervention (PCI), unless there are contraindications such as excessive risk of bleeding.</li> <li>• A proton pump inhibitor (PPI) in combination with dual antiplatelet therapy is recommended in patients at high risk of gastrointestinal bleeding.</li> <li>• In patients with an indication for oral anticoagulation, oral anticoagulants are indicated in addition to antiplatelet therapy</li> <li>• In patients who are at high risk of severe bleeding complications, discontinuation of P2Y<sub>12</sub> inhibitor therapy after six months should be considered.</li> <li>• In STEMI patients with stent implantation and an indication for oral anticoagulation, triple therapy (oral anticoagulant, aspirin, and clopidogrel) should be considered for one to six months (according a balance between the estimated risk of recurrent coronary events and bleeding).</li> <li>• In patients with left ventricular thrombus, anticoagulation should be instituted for a minimum of six months, guided by repeated imaging.</li> <li>• In selected patients who receive aspirin and clopidogrel, low-dose rivaroxaban (2.5 mg twice daily) may be considered if the patient is at low bleeding risk.</li> <li>• Dual antiplatelet therapy should be used up to one year in patients with STEMI who did not receive a stent unless there are contraindications such as excessive risk of bleeding.</li> <li>• In high ischemic-risk patients (age <math>\geq</math>50 years, and at least one of the following</li> </ul>

Clinical Guideline	Recommendations
	<p>risk factors: age <math>\geq 65</math> years, diabetes mellitus on medication, prior spontaneous MAI, multivessel CAD, or chronic renal dysfunction with eGFR <math>&lt; 60</math> mL/min) who have tolerated dual antiplatelet therapy without a bleeding complication, treatment with dual antiplatelet therapy in the form of ticagrelor 60 mg twice a day on top of aspirin for longer than 12 months may be considered for up to three years.</p> <ul style="list-style-type: none"> <li>• The use of ticagrelor or prasugrel is not recommended as part of triple antithrombotic therapy with aspirin and oral anticoagulation.</li> <li>• Oral treatment with <math>\beta</math>-blockers should be considered during hospital stay and continued thereafter in all patients without contraindications.</li> <li>• Oral treatment with <math>\beta</math>-blockers is indicated in patients with heart failure or left ventricular dysfunction, LVEF <math>&lt; 40\%</math> unless contraindicated.</li> <li>• Intravenous <math>\beta</math>-blockers must be avoided in patients with hypotension or acute heart failure or AV block or severe bradycardia.</li> <li>• Intravenous <math>\beta</math>-blockers should be considered at the time of presentation in patients undergoing primary PCI without contraindications, with high blood pressure, tachycardia, and no signs of heart failure.</li> <li>• A fasting lipid profile must be obtained in all STEMI patients, as soon as possible after presentation.</li> <li>• It is recommended to initiate or continue high dose statins early after admission in all STEMI patients without contraindication or history of intolerance, regardless of initial cholesterol values and maintain it long-term.</li> <li>• An LDL-C goal of <math>&lt; 1.8</math> mmol/L (70 mg/dL) or a reduction of at least 50% if the baseline LDL-C is between 1.8 to 3.5 mmol/L (70 to 135 mg/dL) is recommended.</li> <li>• In patients with LDL-C <math>&gt; 1.8</math> mmol/L (<math>&gt; 70</math> mg/dL) despite a maximally tolerated statin dose who remain at high risk, further therapy to reduce LDL-C should be considered.</li> <li>• ACE inhibitors are indicated starting within the first 24 hours of STEMI in patients with evidence of heart failure, LV systolic dysfunction, diabetes or an anterior infarct.</li> <li>• An ARB, preferably valsartan, is an alternative to ACE inhibitors in patients with heart failure or LV systolic dysfunction, particularly those who are intolerant to ACE inhibitors.</li> <li>• ACE inhibitors should be considered in all patients in the absence of contraindications.</li> <li>• Aldosterone antagonists, e.g. eplerenone, are indicated in patients with an ejection fraction <math>\leq 40\%</math> and heart failure or diabetes, provided no renal failure or hyperkalemia.</li> </ul>
<p>American college of Cardiology/ American Heart Association: <b>Guideline on the Primary Prevention of Cardiovascular disease (2019)</b><sup>32</sup></p>	<p><u>Top 10 messages for the primary prevention of cardiovascular disease</u></p> <ul style="list-style-type: none"> <li>• The most important way to prevent atherosclerotic vascular disease, heart failure, and atrial fibrillation is to promote a healthy lifestyle throughout life.</li> <li>• A team-based care approach is an effective strategy for the prevention of cardiovascular disease. Clinicians should evaluate the social determinants of health that affect individuals to inform treatment decisions.</li> <li>• Adults who are 40 to 75 years of age and are being evaluated for cardiovascular disease prevention should undergo 10-year atherosclerotic cardiovascular disease (ASCVD) risk estimation and have a clinician–patient risk discussion before starting on pharmacological therapy, such as antihypertensive therapy, a statin, or aspirin. In addition, assessing for other risk-enhancing factors can help guide decisions about preventive interventions in select individuals, as can coronary artery calcium scanning.</li> <li>• All adults should consume a healthy diet that emphasizes the intake of vegetables, fruits, nuts, whole grains, lean vegetable or animal protein, and fish and minimizes the intake of trans fats, processed meats, refined carbohydrates, and sweetened</li> </ul>

Clinical Guideline	Recommendations
	<p>beverages. For adults with overweight and obesity, counseling and caloric restriction are recommended for achieving and maintaining weight loss.</p> <ul style="list-style-type: none"> <li>• Adults should engage in at least 150 minutes per week of accumulated moderate-intensity physical activity or 75 minutes per week of vigorous-intensity physical activity.</li> <li>• For adults with type 2 diabetes mellitus, lifestyle changes, such as improving dietary habits and achieving exercise recommendations, are crucial. If medication is indicated, metformin is first-line therapy, followed by consideration of a sodium-glucose cotransporter 2 inhibitor or a glucagon-like peptide-1 receptor agonist.</li> <li>• All adults should be assessed at every healthcare visit for tobacco use, and those who use tobacco should be assisted and strongly advised to quit.</li> <li>• Aspirin should be used infrequently in the routine primary prevention of ASCVD because of lack of net benefit.</li> <li>• Statin therapy is first-line treatment for primary prevention of ASCVD in patients with elevated low-density lipoprotein cholesterol levels (<math>\geq 190</math> mg/dL), those with diabetes mellitus, who are 40 to 75 years of age, and those determined to be at sufficient ASCVD risk after a clinician–patient risk discussion.</li> <li>• Nonpharmacological interventions are recommended for all adults with elevated blood pressure or hypertension. For those requiring pharmacological therapy, the target blood pressure should generally be <math>&lt; 130/80</math> mm Hg.</li> </ul> <p><u>Adults with Type 2 Diabetes Mellitus</u></p> <ul style="list-style-type: none"> <li>• For all adults with T2DM, a tailored nutrition plan focusing on a heart-healthy dietary pattern is recommended to improve glycemic control, achieve weight loss if needed, and improve other ASCVD risk factors.</li> <li>• Adults with T2DM should perform at least 150 minutes per week of moderate-intensity physical activity or 75 minutes of vigorous-intensity physical activity to improve glycemic control, achieve weight loss if needed, and improve other ASCVD risk factors.</li> <li>• For adults with T2DM, it is reasonable to initiate metformin as first-line therapy along with lifestyle therapies at the time of diagnosis to improve glycemic control and reduce ASCVD risk.</li> <li>• For adults with T2DM and additional ASCVD risk factors who require glucose-lowering therapy despite initial lifestyle modifications and metformin, it may be reasonable to initiate a sodium-glucose cotransporter 2 (SGLT-2) inhibitor or a glucagon-like peptide-1 receptor (GLP-1R) agonist to improve glycemic control and reduce CVD risk.</li> </ul> <p><u>Adults with high blood cholesterol</u></p> <ul style="list-style-type: none"> <li>• In adults at intermediate risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk), statin therapy reduces risk of ASCVD, and in the context of a risk discussion, if a decision is made for statin therapy, a moderate-intensity statin should be recommended.</li> <li>• In intermediate risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk) patients, LDL-C levels should be reduced by 30% or more, and for optimal ASCVD risk reduction, especially in patients at high risk (<math>\geq 20\%</math> 10-year ASCVD risk), levels should be reduced by 50% or more.</li> <li>• In adults 40 to 75 years of age with diabetes, regardless of estimated 10-year ASCVD risk, moderate-intensity statin therapy is indicated.</li> <li>• In patients 20 to 75 years of age with an LDL-C level of 190 mg/dL (<math>\geq 4.9</math> mmol/L) or higher, maximally tolerated statin therapy is recommended.</li> <li>• In adults with diabetes mellitus who have multiple ASCVD risk factors, it is reasonable to prescribe high-intensity statin therapy with the aim to reduce LDL-C levels by 50% or more.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In intermediate-risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk) adults, risk-enhancing factors favor initiation or intensification of statin therapy.</li> <li>• In intermediate-risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk) adults or selected borderline-risk (<math>5\%</math> to <math>&lt; 7.5\%</math> 10-year ASCVD risk) adults in whom a coronary artery calcium score is measured for the purpose of making a treatment decision, AND <ul style="list-style-type: none"> <li>○ If the coronary artery calcium score is zero, it is reasonable to withhold statin therapy and reassess in five to 10 years, as long as higher-risk conditions are absent (e.g., diabetes, family history of premature CHD, cigarette smoking);</li> <li>○ If coronary artery calcium score is one to 99, it is reasonable to initiate statin therapy for patients <math>\geq 55</math> years of age;</li> <li>○ If coronary artery calcium score is 100 or higher or in the 75th percentile or higher, it is reasonable to initiate statin therapy.</li> </ul> </li> <li>• In patients at borderline risk (<math>5\%</math> to <math>&lt; 7.5\%</math> 10-year ASCVD risk), in risk discussion, the presence of risk-enhancing factors may justify initiation of moderate-intensity statin therapy.</li> </ul> <p><u>Adults with high blood pressure or hypertension</u></p> <ul style="list-style-type: none"> <li>• In adults with elevated blood pressure (BP) or hypertension, including those requiring antihypertensive medications nonpharmacological interventions are recommended to reduce BP. These include: <ul style="list-style-type: none"> <li>○ weight loss;</li> <li>○ a heart-healthy dietary pattern;</li> <li>○ sodium reduction;</li> <li>○ dietary potassium supplementation;</li> <li>○ increased physical activity with a structured exercise program; and</li> <li>○ limited alcohol.</li> </ul> </li> <li>• In adults with an estimated 10-year ASCVD risk (ACC/AHA pooled cohort equations to estimate 10-year risk of ASCVD) of 10% or higher and an average systolic BP (SBP) of 130 mm Hg or higher or an average diastolic BP (DBP) of 80 mm Hg or higher, use of BP-lowering medications is recommended for primary prevention of CVD.</li> <li>• In adults with confirmed hypertension and a 10-year ASCVD event risk of 10% or higher, a BP target of less than 130/80 mm Hg is recommended.</li> <li>• In adults with hypertension and chronic kidney disease, treatment to a BP goal of less than 130/80 mm Hg is recommended.</li> <li>• In adults with T2DM and hypertension, antihypertensive drug treatment should be initiated at a BP of 130/80 mm Hg or higher, with a treatment goal of less than 130/80 mm Hg.</li> <li>• In adults with an estimated 10-year ASCVD risk <math>&lt; 10\%</math> and an SBP of 140 mm Hg or higher or a DBP of 90 mm Hg or higher, initiation and use of BP-lowering medication are recommended.</li> <li>• In adults with confirmed hypertension without additional markers of increased ASCVD risk, a BP target of less than 130/80 mm Hg may be reasonable.</li> </ul> <p><u>Recommendations for treatment of tobacco use</u></p> <ul style="list-style-type: none"> <li>• All adults should be assessed at every healthcare visit for tobacco use and their tobacco use status recorded as a vital sign to facilitate tobacco cessation.</li> <li>• To achieve tobacco abstinence, all adults who use tobacco should be firmly advised to quit.</li> <li>• In adults who use tobacco, a combination of behavioral interventions plus pharmacotherapy is recommended to maximize quit rates.</li> <li>• In adults who use tobacco, tobacco abstinence is recommended to reduce ASCVD risk.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>To facilitate tobacco cessation, it is reasonable to dedicate trained staff to tobacco treatment in every healthcare system.</li> <li>All adults and adolescents should avoid secondhand smoke exposure to reduce ASCVD risk.</li> </ul> <p><u>Recommendations for aspirin use</u></p> <ul style="list-style-type: none"> <li>Low-dose aspirin (75 to 100 mg orally daily) might be considered for the primary prevention of ASCVD among select adults 40 to 70 years of age who are at higher ASCVD risk but not at increased bleeding risk.</li> <li>Low-dose aspirin (75 to 100 mg orally daily) should not be administered on a routine basis for the primary prevention of ASCVD among adults &gt;70 years of age.</li> <li>Low-dose aspirin (75 to 100 mg orally daily) should not be administered for the primary prevention of ASCVD among adults of any age who are at increased risk of bleeding.</li> </ul>
<p>American Heart Association/American College of Cardiology/Heart Failure Society of America: <b>2022 AHA/ACC/HFSA Guideline for the Management of Heart Failure (2022)</b><sup>33</sup></p>	<p><u>Treatment of Stage A heart failure (HF)</u></p> <ul style="list-style-type: none"> <li>Hypertension should be controlled in accordance with guideline-directed medication therapy for hypertension to prevent symptomatic HF. (LoE: A)</li> <li>In patients with type 2 diabetes and either established CVD or at high cardiovascular risk, SGLT-2 inhibitors should be used to prevent hospitalizations for HF. (LoE: A)</li> <li>In the general population, healthy lifestyle habits such as regular physical activity, maintaining normal weight, healthy dietary patterns, and avoiding smoking are helpful to reduce future risk of HF. (LoE: B)</li> <li>Patients at risk of developing HF, natriuretic peptide biomarker-based screening followed by team-based care, including a cardiovascular specialist optimizing therapy, can be useful to prevent the development of LV dysfunction (systolic or diastolic) or new-onset HF. (LoE: B)</li> </ul> <p><u>Treatment of Stage B heart failure</u></p> <ul style="list-style-type: none"> <li>In patients with LVEF≤40%, ACE inhibitors should be used to prevent HF and reduce mortality. (LoE: A)</li> <li>In patients with a recent or remote history of MI or ACS, statins should be used to prevent symptomatic HF and adverse cardiovascular events. (LoE: A)</li> <li>In patients with a recent MI and LVEF≤40% who are intolerant to ACE inhibitors, ARB should be used to prevent symptomatic HF and reduce mortality. (LoE: B)</li> <li>In patients with a recent or remote history of MI or ACS and LVEF≤40%, evidence-based beta blockers should be used to reduce mortality. (LoE: B)</li> <li>In patients who are at least 40 days post-MI with LVEF ≤30% and NYHA class I symptoms while receiving guideline-directed medication therapy and have reasonable expectation of meaningful survival for greater than one year, an implantable cardioverter-defibrillator is recommended for primary prevention of sudden cardiac death to reduce total mortality. (LoE: B)</li> <li>In patients with LVEF ≤40%, beta blockers should be used to prevent symptomatic HF. (LoE: C)</li> <li>In patients with LVEF ≤50%, thiazolidinediones should not be used because they increase the risk of HF, including hospitalizations. (LoE: B)</li> <li>In patients with LVEF ≤50%, nondihydropyridine calcium channel blockers with negative inotropic effects may be harmful. (LoE: C)</li> </ul> <p><u>Treatment for Stage C Heart Failure with Reduced Ejection Fraction (HFrEF)</u></p> <ul style="list-style-type: none"> <li>For patients with stage C HF, avoiding excessive sodium intake is reasonable to reduce congestive symptoms. (LoE: C)</li> <li>In patients with HF who have fluid retention, diuretics are recommended to relieve congestion, improve symptoms, and prevent worsening HF. (LoE: B)</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• For patients with HF and congestive symptoms, addition of a thiazide (e.g., metolazone) to treatment with a loop diuretic should be reserved for patients who do not respond to moderate or high dose loop diuretics to minimize electrolyte abnormalities. (LoE: B)</li> <li>• In patients with HFrEF and NYHA class II to III symptoms, the use of an ARNI is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, the use of an ACE inhibitor is beneficial to reduce morbidity and mortality when the use of an ARNI is not feasible. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, who are intolerant to an ACE inhibitor because of cough or angioedema, and when the use of an ARNI is not feasible, the use of an ARB is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with chronic symptomatic HFrEF NYHA class II or III who tolerate an ACE inhibitor or ARB, replacement by an ARNI is recommended to further reduce morbidity and mortality. (LoE: B)</li> <li>• ARNIs should not be administered concomitantly with ACE inhibitors or within 36 hours of the last dose of an ACE inhibitor. (LoE: B)</li> <li>• ARNI or ACE inhibitors should not be administered in patients with a history of angioedema. (LoE: C)</li> <li>• In patients with HFrEF, with current or previous symptoms, use of one of the three <math>\beta</math>-blockers proven to reduce mortality (e.g., bisoprolol, carvedilol, sustained-release metoprolol succinate) is recommended to reduce mortality and hospitalizations. (LoE: A)</li> <li>• In patients with HFrEF and NYHA class II to IV symptoms, a mineralocorticoid receptor antagonist (spironolactone or eplerenone) is recommended to reduce morbidity and mortality, if eGFR is <math>&gt;30</math> mL/min/1.73 m<sup>2</sup> and serum potassium is <math>&lt;5.0</math> mEq/L. Careful monitoring of potassium, renal function, and diuretic dosing should be performed at initiation and closely followed thereafter to minimize risk of hyperkalemia and renal insufficiency. (LoE: A)</li> <li>• In patients taking a mineralocorticoid receptor antagonist whose serum potassium cannot be maintained at <math>&lt;5.5</math> mEq/L, mineralocorticoid receptor antagonist should be discontinued to avoid life threatening hyperkalemia. (LoE: B)</li> <li>• In patients with symptomatic chronic HFrEF, SGLT-2 an inhibitor is recommended to reduce hospitalization for HF and cardiovascular mortality, irrespective of the presence of type 2 diabetes. (LoE: A)</li> <li>• The combination of hydralazine and isosorbide dinitrate is recommended to improve symptoms and reduce morbidity and mortality for patients self-identified as African Americans with NYHA class III to IV HFrEF receiving optimal therapy. (LoE: A)</li> <li>• In patients with current or previous symptomatic HFrEF who cannot be given first-line agents, such as an ARNI, ACE inhibitor or ARB because of drug intolerance or renal insufficiency, a combination of hydralazine and isosorbide dinitrate might be considered to reduce morbidity and mortality. (LoE: C)</li> <li>• In patients with HF class II to IV symptoms, omega-3 polyunsaturated fatty acid supplementation may be reasonable to use as adjunctive therapy to reduce mortality and cardiovascular hospitalizations. (LoE: B)</li> <li>• In patients with chronic HFrEF without specific indication (e.g., venous thromboembolism, atrial fibrillation, a previous thromboembolic event, or a cardioembolic source, anticoagulation is not recommended. (LoE: B)</li> <li>• Dihydropyridine and non-dihydropyridine calcium channel blockers are not recommended for patients with HFrEF. (LoE: A)</li> <li>• In patients with HFrEF, vitamins, nutritional supplements, and hormonal therapy are not recommended other than to correct specific deficiencies. (LoE: B)</li> <li>• In patients with HFrEF, class IC antiarrhythmic medication and dronedarone may</li> </ul>

Clinical Guideline	Recommendations
	<p>increase risk of mortality. (LoE: A)</p> <ul style="list-style-type: none"> <li>• In patients with HFrEF, thiazolidinediones increase the risk of worsening HF symptoms and hospitalizations. (LoE: A)</li> <li>• In patients with type 2 diabetes and high cardiovascular risk, the DPP-4 inhibitors, saxagliptin and alogliptin, increase the risk of HF hospitalization and should be avoided in patients with HF. (LoE: B)</li> <li>• In patients with HFrEF, nonsteroidal anti-inflammatory drugs worsen HF symptoms and should be avoided or withdrawn whenever possible. (LoE: B)</li> <li>• For patients with symptomatic (NYHA class II to III) stable chronic HFrEF (LVEF <math>\leq</math>35%) who are receiving guideline-directed medical therapy, including a maximally tolerated dose of a beta blocker, and who are in sinus rhythm with a heart rate of <math>\geq</math>70 beats per minute at rest, ivabradine can be beneficial to reduce HF hospitalizations and cardiovascular death. (LoE: B)</li> <li>• In patients with symptomatic HFrEF despite guideline-directed medical therapy or who are unable to tolerate guideline-directed medical therapy, digoxin might be considered to decrease hospitalizations for HF. (LoE: B)</li> <li>• In select high-risk patients with HFrEF and recent worsening of HF already on guideline-directed medical therapy, an oral soluble guanylate cyclase stimulator (vericiguat) may be considered to reduce HF hospitalization and cardiovascular death. (LoE: B)</li> </ul> <p><u>Pharmacological treatment for Stage C HF with mildly reduced EF and improved EF</u></p> <ul style="list-style-type: none"> <li>• In patients with HF with mildly reduced EF, SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• Among patients with current or previous symptomatic HF with mildly reduced EF (LVEF, 41 to 49%), use of evidence-based beta blockers for HFrEF, ARNI, ACE inhibitor or ARB, and mineralocorticoid receptor antagonists may be considered to reduce the risk of HF hospitalization and cardiovascular mortality, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• In patients with HF with improved EF after treatment, guideline-directed medical therapy should be continued to prevent relapse of HF and LV dysfunction, even in patients who may become asymptomatic. (LoE: B)</li> </ul> <p><u>Pharmacological treatment for Stage C HF with preserved EF (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• Patients with hypertension and HFpEF should have medication titrated to attain blood pressure targets in accordance with published clinical practice guidelines to prevent morbidity. (LoE: C)</li> <li>• SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• In patients with HFpEF, the use of a mineralocorticoid receptor antagonist, ARB, or ARNI may be considered to decrease hospitalizations, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• Routine use of nitrates or phosphodiesterase-5 inhibitors to increase activity or quality of life in patients with HFpEF is ineffective. (LoE: B)</li> </ul> <p><u>Treatment of Stage D (advanced/refractory) HF</u></p> <ul style="list-style-type: none"> <li>• For patients with advanced HF and hyponatremia, the benefit of fluid restriction to reduce congestive symptoms is uncertain. (LoE: C)</li> <li>• Continuous intravenous inotropic support is reasonable as “bridge therapy” in patients with HF (Stage D) refractory to guideline-directed medical therapy and device therapy who are eligible for and awaiting mechanical circulatory support or cardiac transplantation. (LoE: B)</li> <li>• In select patients with HF Stage D, despite optimal guideline-directed medical therapy and device therapy who are ineligible for either mechanical circulatory support or cardiac transplantation, continuous intravenous inotropic support may</li> </ul>

Clinical Guideline	Recommendations
	<p>be considered as palliative therapy for symptom control and improvement in functional status. (LoE: B)</p> <ul style="list-style-type: none"> <li>Long-term use of either continuous or intermittent, intravenous inotropic agents, for reasons other than palliative care or as a bridge to advanced therapies, is potentially harmful. (LoE: B)</li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure (2021)</b><sup>34</sup></p>	<p><b>Pharmacological treatments indicated in patients with (NYHA Class II-IV) heart failure with reduced ejection fraction</b></p> <ul style="list-style-type: none"> <li>An ACE inhibitor is recommended, in addition to a <math>\beta</math>-blocker, for symptomatic patients with HFrEF to reduce the risk of HF hospitalization and death.</li> <li>A mineralocorticoid receptor antagonist (MRA) is recommended for patients with HFrEF, who remain symptomatic despite treatment with an ACE inhibitor and a <math>\beta</math>-blocker, to reduce the risk of HF hospitalization and death.</li> <li>Dapagliflozin or empagliflozin are recommended for patients with HFrEF to reduce the risk of HF hospitalization and death. Dapagliflozin or empagliflozin are recommended, in addition to optimal medical therapy with an ACE-I/ARNI, a <math>\beta</math>-blocker and an MRA, for patients with HFrEF regardless of diabetes status.</li> <li>Sacubitril-valsartan is recommended as a replacement for an ACE inhibitor to further reduce the risk of HF hospitalization and death in ambulatory patients with HFrEF who remain symptomatic despite optimal treatment with an ACE inhibitor, a <math>\beta</math>-blocker, and a mineralocorticoid receptor antagonist.</li> <li>Diuretics are recommended in order to improve symptoms and exercise capacity in patients with signs and/or symptoms of congestion.</li> <li>Ivabradine should be considered to reduce the risk of HF hospitalization or cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm despite treatment with an evidence-based dose of <math>\beta</math>-blocker (or maximum tolerated dose below that), ACE inhibitor (or ARB), and a mineralocorticoid receptor antagonist (or ARB).</li> <li>Ivabradine should be considered to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm who are unable to tolerate or have contraindications for a <math>\beta</math>-blocker. Patients should also receive an ACE inhibitor (or ARB) and a mineralocorticoid receptor antagonist (or ARB).</li> <li>An ARB is recommended to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients unable to tolerate an ACE inhibitor (patients should also receive a <math>\beta</math>-blocker and mineralocorticoid receptor antagonist).</li> <li>An ARB may be considered to reduce the risk of HF hospitalization and death in patients who are symptomatic despite treatment with a <math>\beta</math>-blocker who are unable to tolerate a mineralocorticoid receptor antagonist.</li> <li>Vericiguat may be considered in patients in NYHA class II-IV who have had worsening HF despite treatment with an ACE-I (or ARNI), a <math>\beta</math>-blocker and an MRA to reduce the risk of CV mortality or HF hospitalization.</li> <li>Hydralazine and isosorbide dinitrate should be considered in self-identified black patients with LVEF <math>\leq 35\%</math> or with an LVEF <math>&lt; 45\%</math> combined with a dilated LV in NYHA Class III-IV despite treatment with an ACE-I a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist to reduce the risk of HF hospitalization and death.</li> <li>Hydralazine and isosorbide dinitrate may be considered in symptomatic patients with HFrEF who can tolerate neither an ACE inhibitor nor an ARB (or they are contraindicated) to reduce the risk of death.</li> <li>Digoxin is a treatment with less-certain benefits and may be considered in symptomatic patients in sinus rhythm despite treatment with an ACE inhibitor (or ARB), a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist, to reduce the risk of hospitalization (both all-cause and HF-hospitalizations).</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Recommendations for treatment of patients with (NYHA class II-IV) heart failure with mildly reduced ejection fraction (HFmrEF)</u></p> <ul style="list-style-type: none"> <li>• Diuretics are recommended in patients with congestion and HFmrEF in order to alleviate symptoms and signs.</li> <li>• An ACE inhibitor may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An ARB may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• A <math>\beta</math>-blocker may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An MRA may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• Sacubitril/valsartan may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> </ul> <p><u>Recommendations for treatment of patients with heart failure with preserved ejection fraction (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• It is recommended to screen patients with HFpEF for both cardiovascular and noncardiovascular comorbidities, which, if present, should be treated provided safe and effective interventions exist to improve symptoms, well-being and/or prognosis.</li> <li>• Diuretics are recommended in congested patients with HFpEF in order to alleviate symptoms and signs.</li> </ul> <p><u>Recommendations for the primary prevention of heart failure in patients with risk factors for its development</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension is recommended to prevent or delay the onset of HF and prolong life.</li> <li>• Treatment with statins is recommended in patients at high risk of CV disease or with CV disease in order to prevent or delay the onset of HF, and to prevent HF hospitalizations.</li> <li>• SGLT2 inhibitors (canagliflozin, dapagliflozin, empagliflozin, ertugliflozin, sotagliflozin) are recommended in patients with diabetes at high risk of CV disease or with CV disease in order to prevent HF hospitalizations.</li> <li>• Counselling against sedentary habit, obesity, cigarette smoking, and alcohol abuse is recommended to prevent or delay the onset of HF.</li> </ul> <p><u>Recommendations for the initial management of patients with acute heart failure – pharmacotherapy</u></p> <ul style="list-style-type: none"> <li>• Intravenous loop diuretics are recommended for all patients with acute HF admitted with signs/symptoms of fluid overload to improve symptoms. It is recommended to regularly monitor symptoms, urine output, renal function and electrolytes during use of intravenous diuretics.</li> <li>• Combination of a loop diuretic with thiazide type diuretic should be considered in patients with resistant oedema who do not respond to an increase in loop diuretic doses.</li> <li>• In patients with acute HF and SBP &gt;110 mmHg, intravenous vasodilators may be considered as initial therapy to improve symptoms and reduce congestion.</li> <li>• Inotropic agents may be considered in patients with SBP &lt;90 mmHg and evidence of hypoperfusion who do not respond to standard treatment, including fluid challenge, to improve peripheral perfusion and maintain end-organ function.</li> <li>• Inotropic agents are not recommended routinely, due to safety concerns, unless the patient has symptomatic hypotension and evidence of hypoperfusion.</li> <li>• A vasopressor, preferably norepinephrine, may be considered in patients with cardiogenic shock to increase blood pressure and vital organ perfusion.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Thromboembolism prophylaxis (e.g., with LMWH) is recommended in patients not already anticoagulated and with no contraindication to anticoagulation, to reduce the risk of deep venous thrombosis and pulmonary embolism.</li> <li>• Routine use of opiates is not recommended, unless in selected patients with severe/intractable pain or anxiety.</li> </ul>
<p>American Heart Association/ American College of Cardiology/ Heart Rhythm Society: <b>2019</b> <b>AHA/ACC/HRS Focused update of the 2014</b> <b>AHA/ACC/ARS Guideline for the Management of Patients with Atrial Fibrillation (2019)</b><sup>35</sup></p>	<p><u>Recommendations for risk-based anticoagulant therapy:</u></p> <p><b>Class I</b></p> <ul style="list-style-type: none"> <li>• In patients with atrial fibrillation (AF), anticoagulant therapy should be individualized based on shared decision-making after discussion of the absolute and relative risks of stroke, bleeding and the patient’s values and preferences (Level of Evidence: C).</li> <li>• NOACs (dabigatran, rivaroxaban, apixaban, and edoxaban) are recommended over warfarin in NOAC-eligible patients with AF (except with moderate-to-severe mitral stenosis or a mechanical heart valve) (Level of Evidence: A).</li> <li>• Selection of anticoagulant therapy should be based on the risk of thromboembolism irrespective of whether the AF patten is paroxysmal, persistent, or permanent (Level of Evidence: B).</li> <li>• In patients with AF (except with moderate-to-severe mitral stenosis or a mechanical heart valve), the CHA<sub>2</sub>DS<sub>2</sub>-VASc score is recommended for assessment of stroke risk (Level of Evidence: B). For patients with AF who have mechanical heart valves, warfarin is recommended. (Level of Evidence: B).</li> <li>• Selection of anticoagulant therapy should be based on the risk of thromboembolism, irrespective of whether the AF pattern is paroxysmal, persistent, or permanent.</li> <li>• For patients with AF and an elevated CHA<sub>2</sub>DS<sub>2</sub>-VASc score <math>\geq 2</math> in men or <math>\geq 3</math> in women, oral anticoagulants are recommended. Options include warfarin (Level of Evidence: A), dabigatran, rivaroxaban, apixaban, or edoxaban. (Level of Evidence: B).</li> <li>• Among patients treated with warfarin, the INR should be determined at least weekly during initiation of anticoagulant therapy and at least monthly when anticoagulation (INR in range) is stable (Level of Evidence: A)</li> <li>• For patients with AF (except with moderate-to-severe mitral stenosis or a mechanical heart valve) who are unable to maintain a therapeutic INR level with warfarin, use of a non-vitamin K oral anticoagulant (NOAC) is recommended (Level of Evidence: C-EO).</li> <li>• Re-evaluation of the need for and choice of anticoagulant therapy at periodic intervals is recommended to reassess stroke and bleeding risks (Level of Evidence: C).</li> <li>• Renal function should be evaluated prior to initiation of a NOAC and should be re-evaluated when clinically indicated and at least annually (Level of Evidence: B-NR).</li> <li>• For patients with atrial flutter, anticoagulant therapy is recommended according to the same risk profile used for AF (Level of Evidence: C).</li> </ul> <p><b>Class IIa</b></p> <ul style="list-style-type: none"> <li>• For patients with AF (except with moderate-to-severe mitral stenosis or a mechanical heart valve) and a CHA<sub>2</sub>DS<sub>2</sub>-VASc score of 0 in men or 1 in women, it is reasonable to omit antithrombotic therapy (Level of Evidence: B).</li> <li>• For patients with AF with a CHA<sub>2</sub>DS<sub>2</sub>-VASc score of <math>\geq 2</math> in men or <math>\geq 3</math> in women and who have end-stage chronic kidney disease (creatinine clearance <math>&lt; 15</math> mL/min) or who are on dialysis, it is reasonable to prescribe warfarin (INR 2.0 to 3.0) or apixaban for oral anticoagulation (Level of Evidence: B).</li> </ul> <p><b>Class IIb</b></p> <ul style="list-style-type: none"> <li>• For patients with AF (except with moderate-to-severe mitral stenosis or a mechanical heart valve) and a CHA<sub>2</sub>DS<sub>2</sub>-VASc score of 1 in men and 2 in women, prescribing an oral anticoagulant to reduce thromboembolic stroke risk may be</li> </ul>

Clinical Guideline	Recommendations
	<p>considered. 	<p>genetic testing are recommended.</p> <p><u>Class IIa recommendation</u></p> <ul style="list-style-type: none"> <li>In patients with suspected long QT syndrome, ambulatory electrocardiographic monitoring, recording the ECG lying and immediately on standing, and/or exercise treadmill testing can be useful for establishing a diagnosis and monitoring the response to therapy.</li> <li>In asymptomatic patients with long QT syndrome and a resting QTc less than 470 ms, chronic therapy with a beta blocker is reasonable.</li> </ul> <p><u>Class IIb recommendation</u></p> <ul style="list-style-type: none"> <li>In asymptomatic patients with long QT syndrome and a resting QTc greater than 500 ms while receiving a beta blocker, intensification of therapy with medications (guided by consideration of the particular long QT syndrome type), left cardiac sympathetic denervation or an ICD may be considered.</li> </ul> <p><u>Class III: harm recommendation</u></p> <ul style="list-style-type: none"> <li>In patients with long QT syndrome, QT prolonging medications are potentially harmful.</li> </ul> <p><u>Recommendation for Catecholaminergic Polymorphic Ventricular Tachycardia</u></p> <p><u>Class I recommendation</u></p> <ul style="list-style-type: none"> <li>In patients with catecholaminergic polymorphic ventricular tachycardia, a beta blocker is recommended.</li> <li>In patients with catecholaminergic polymorphic ventricular tachycardia and recurrent sustained VT or syncope, while receiving adequate or maximally tolerated beta blocker, treatment intensification with either combination medication therapy (e.g., beta blocker, flecainide), left cardiac sympathetic denervation, and/or an ICD is recommended.</li> </ul> <p><u>Class IIa recommendation</u></p> <ul style="list-style-type: none"> <li>In patients with catecholaminergic polymorphic ventricular tachycardia and with clinical VT or exertional syncope, genetic counseling and genetic testing are reasonable.</li> </ul> <p><u>Recommendation for short QT Syndrome</u></p> <p><u>Class I recommendation</u></p> <ul style="list-style-type: none"> <li>In patients with short QT syndrome who have a cardiac arrest or sustained VA, an ICD is recommended if meaningful survival greater than one year is expected.</li> </ul> <p><u>Class IIa recommendation</u></p> <ul style="list-style-type: none"> <li>In patients with short QT syndrome and recurrent sustained VA, treatment with quinidine can be useful.</li> <li>In patients with short QT syndrome and VT/ VF storm, isoproterenol infusion can be effective.</li> </ul> <p><u>Class IIb recommendation</u></p> <ul style="list-style-type: none"> <li>In patients with short QT syndrome, genetic testing may be considered to facilitate screening of first-degree relatives.</li> </ul> <p><u>Recommendation for VA in the Structurally Normal Heart</u></p> <p><u>Class I recommendation</u></p> <ul style="list-style-type: none"> <li>In patients with symptomatic premature ventricular complexes (PVCs) in an otherwise normal heart, treatment with a beta blocker or nondihydropyridine calcium channel blocker is useful to reduce recurrent arrhythmias and improve symptoms.</li> </ul> <p><u>Class IIa recommendation</u></p> <ul style="list-style-type: none"> <li>In patients with symptomatic VA in an otherwise normal heart, treatment with an antiarrhythmic medication is reasonable to reduce recurrent symptomatic arrhythmias and improve symptoms if beta blockers and nondihydropyridine calcium channel blockers are ineffective or not tolerated.</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Recommendation for Outflow Tract VA</u>  <u>Class I recommendation</u></p> <ul style="list-style-type: none"> <li>• In patients with symptomatic outflow tract VA in an otherwise normal heart for whom antiarrhythmic medications are ineffective, not tolerated, or not the patient's preference, catheter ablation is useful.</li> <li>• In patients with symptomatic outflow tract VT in an otherwise normal heart, a beta blocker or a calcium channel blocker is useful.</li> </ul> <p><u>Recommendation for PVC-Induced Cardiomyopathy</u>  <u>Class I recommendation</u></p> <ul style="list-style-type: none"> <li>• For patients who require arrhythmia suppression for symptoms or declining ventricular function suspected to be due to frequent PVCs (generally &gt;15% of beats and predominately of 1 morphology) and for whom antiarrhythmic medications are ineffective, not tolerated, or not the patient's preference, catheter ablation is useful.</li> </ul> <p><u>Class IIa recommendation</u></p> <ul style="list-style-type: none"> <li>• In patients with PVC-induced cardiomyopathy, pharmacological treatment (e.g., beta blocker, amiodarone) is reasonable to reduce recurrent arrhythmias and improve symptoms and LV function.</li> </ul> <p><u>Recommendation for Pregnancy</u>  <u>Class I recommendation</u></p> <ul style="list-style-type: none"> <li>• In mothers with long QT syndrome, a beta blocker should be continued during pregnancy and throughout the postpartum period including in women who are breastfeeding.</li> <li>• In the pregnant patient with sustained VA, electrical cardioversion is safe and effective and should be used with standard electrode configuration.</li> </ul> <p><u>Class IIa recommendation</u></p> <ul style="list-style-type: none"> <li>• In pregnant patients needing an ICD or VT ablation, it is reasonable to undergo these procedures during pregnancy, preferably after the first trimester.</li> </ul> <p><u>Recommendation for Medication-Induced Arrhythmias</u>  <u>Class I recommendation</u></p> <ul style="list-style-type: none"> <li>• Administration of digoxin antibodies is recommended for patients who present with sustained VA potentially due to digoxin toxicity.</li> <li>• In patients with recurrent torsades de pointes associated with acquired QT prolongation and bradycardia that cannot be suppressed with intravenous magnesium administration, increasing the heart rate with atrial or ventricular pacing or isoproterenol are recommended to suppress the arrhythmia.</li> <li>• For patients with QT prolongation due to a medication, hypokalemia, hypomagnesemia, or other acquired factor and recurrent torsades de pointes, administration of intravenous magnesium sulfate is recommended to suppress the arrhythmia.</li> <li>• For patients with torsades de pointes associated with acquired QT prolongation, potassium repletion to 4.0 mmol/L or more and magnesium repletion to normal values (e.g., <math>\geq 2.0</math> mmol/L) are beneficial.</li> </ul> <p><u>Class IIa recommendation</u></p> <ul style="list-style-type: none"> <li>• In patients taking sodium channel blockers who present with elevated defibrillation or pacing thresholds, discontinuing the presumed responsible medication or reprogramming the device can be useful to restore effective device therapy.</li> </ul> <p><u>Class III: harm recommendation</u></p> <ul style="list-style-type: none"> <li>• In patients with congenital or acquired long QT syndrome, QT-prolonging medications are potentially harmful.</li> </ul>

Clinical Guideline	Recommendations
<p>European Society of Cardiology: <b>Guidelines on diagnosis and management of hypertrophic cardiomyopathy (2014)</b><sup>39</sup></p>	<ul style="list-style-type: none"> <li>• Patients with symptomatic left ventricular outflow tract obstruction should be treated initially with non-vasodilating <math>\beta</math>-blockers titrated to maximum tolerable dose.</li> <li>• If <math>\beta</math>-blockers alone are ineffective, disopyramide titrated to a maximum tolerated dose (usually 400 to 600 mg/day) may be added.</li> <li>• Verapamil can be used when <math>\beta</math>-blockers are contraindicated or ineffective, but close monitoring is required in patients with severe obstruction (<math>\geq 100</math> mmHg) or elevated pulmonary artery systolic pressures, as it can provoke pulmonary edema.</li> <li>• Nifedipine and other dihydropyridine calcium antagonists are not recommended.</li> <li>• Low-dose loop or thiazide diuretics may be used cautiously to improve dyspnea, but it is important to avoid hypovolemia.</li> <li>• In patients without left ventricular outflow tract obstruction, An ACE inhibitor (or ARB if ACE inhibitor not tolerated) should be considered, in addition to a <math>\beta</math>-blocker, for patients who have an LVEF <math>&lt; 50\%</math>, to reduce the risks of HF hospitalization and premature death.</li> </ul>
<p>Eighth Joint National Committee (JNC 8): <b>2014 Evidence-based Guideline for the Management of High Blood Pressure in Adults (2014)</b><sup>40</sup></p>	<ul style="list-style-type: none"> <li>• Pharmacologic treatment should be initiated in patients <math>\geq 60</math> years of age to lower blood pressure at systolic blood pressure <math>\geq 150</math> mm Hg or diastolic blood pressure <math>\geq 90</math> mm Hg and to a goal systolic blood pressure <math>&lt; 150</math> mm Hg and goal diastolic blood pressure <math>&lt; 90</math> mm Hg. Adjustment of treatment is not necessary if treatment results in lower blood pressure and treatment is well tolerated and without adverse effects on health or quality of life.</li> <li>• In patients <math>&lt; 60</math> years of age, pharmacologic treatment should be initiated to lower blood pressure at diastolic blood pressure <math>\geq 90</math> mm Hg to a goal diastolic blood pressure <math>&lt; 90</math> mm Hg.</li> <li>• In patients <math>&lt; 60</math> years of age, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure <math>\geq 150</math> mm Hg to a goal diastolic blood pressure <math>&lt; 140</math> mm Hg.</li> <li>• For patients <math>\geq 18</math> years of age with chronic kidney disease or diabetes, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure <math>\geq 140</math> mm Hg or diastolic blood pressure <math>\geq 90</math> mm Hg and to a goal systolic blood pressure <math>&lt; 140</math> mm Hg and goal diastolic blood pressure <math>&lt; 90</math> mm Hg.</li> <li>• Initial antihypertensive treatment for the general nonblack population, including those with diabetes, should include thiazide-type diuretic, calcium channel blocker (CCB), ACE inhibitor, or ARB.</li> <li>• Initial antihypertensive treatment for the general black population, including those with diabetes, should include thiazide-type diuretic or CCB.</li> <li>• For patients <math>\geq 18</math> years of age with chronic kidney disease regardless of race or diabetes status, initial (or add-on) treatment should include an ACE inhibitor or ARB to improve kidney outcomes.</li> <li>• The main goal of antihypertensive treatment is to attain and maintain goal blood pressure.</li> <li>• If goal blood pressure is not attained within a month of treatment, the dose of the initial drug should be increased or second drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• If goal is not achieved with two drugs, a third drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• An ACE inhibitor and ARB should not be used together.</li> <li>• Antihypertensive classes can be used if the patient is unable to achieve goal blood pressure with three agents or had a contraindication to a preferred class.</li> <li>• If blood pressure is not able to be achieved or in complicated patients, referral to a hypertension specialist may be indicated.</li> </ul>
<p>International Society of Hypertension: <b>Global</b></p>	<p><u>Lifestyle modifications</u></p> <ul style="list-style-type: none"> <li>• Lifestyle modification is the first line of antihypertensive treatment.</li> <li>• Salt reduction: Reduce salt added when preparing foods, and at the table. Avoid or</li> </ul>

Clinical Guideline	Recommendations
<p><b>Hypertension Practice Guidelines (2020)<sup>41</sup></b></p>	<p>limit consumption of high salt foods such as soy sauce, fast foods and processed food including breads and cereals high in salt.</p> <ul style="list-style-type: none"> <li>• Healthy diet: Eating a diet that is rich in whole grains, fruits, vegetables, polyunsaturated fats and dairy products and reducing food high in sugar, saturated fat and trans fats, such as the DASH diet.</li> <li>• Healthy drinks: Moderate consumption of coffee, green and black tea. Other beverages that can be beneficial include karkadé (hibiscus) tea, pomegranate juice, beetroot juice and cocoa.</li> <li>• Moderation of alcohol consumption: The recommended daily limit for alcohol consumptions is two standard drinks for men and 1.5 for women (10 g alcohol/standard drink). Avoid binge drinking.</li> <li>• Weight reduction: Body weight control is indicated to avoid obesity. Particularly abdominal obesity should be managed. Ethnic-specific cut-offs for BMI and waist circumference should be used. Alternatively, a waist-to-height ratio &lt;0.5 is recommended for all populations.</li> <li>• Smoking cessation: Smoking is a major risk factor for cardiovascular disease (CVD), COPD and cancer. Smoking cessation and referral to smoking cessation programs are advised.</li> <li>• Regular physical activity: Studies suggest that regular aerobic and resistance exercise may be beneficial for both the prevention and treatment of hypertension. Moderate intensity aerobic exercise (walking, jogging, cycling, yoga, or swimming) for 30 minutes on five to seven days per week Strength training also can help reduce blood pressure. Performance of resistance/strength exercises on two to three days per week.</li> <li>• Reduce stress and induce mindfulness: Stress should be reduced and mindfulness or meditation introduced into the daily routine.</li> <li>• Reduce exposure to air pollution and cold temperature: Evidence from studies support a negative effect of air pollution on blood pressure in the long-term.</li> </ul> <p><b>Pharmacological Treatment</b></p> <ul style="list-style-type: none"> <li>• Ideal characteristics of drug treatment <ul style="list-style-type: none"> <li>○ Treatments should be evidence-based in relation to morbidity/mortality prevention.</li> <li>○ Use a once-daily regimen which provides 24-hour blood pressure control.</li> <li>○ Treatment should be affordable and/or cost-effective relative to other agents.</li> <li>○ Treatments should be well-tolerated.</li> <li>○ Evidence of benefits of use of the medication in populations to which it is to be applied.</li> </ul> </li> <li>• General scheme for drug treatment <ul style="list-style-type: none"> <li>○ Lifestyle modification is the first line of antihypertensive treatment.</li> <li>○ Grade 1 hypertension (BP 140 to 159/ 90 to 99): Immediate drug treatment in high-risk patients or those with CVD, chronic kidney disease (CKD), diabetes mellitus (DM), or hypertension-mediated organ damage (HMOD). Drug treatment after three to six months of lifestyle intervention if BP still not controlled in low to moderate risk patients.</li> <li>○ Grade 2 hypertension (BP ≥160/100): Immediate drug treatment in all patients.</li> </ul> </li> <li>• Core drug-treatment strategy <ul style="list-style-type: none"> <li>○ Step 1: Dual low-dose combination (ACE inhibitor or ARB plus dihydropyridine-calcium channel blockers (DHP-CCB)); consider monotherapy in low-risk grade 1 hypertension or in very old (≥80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance; consider ACE/ARB plus DHP-CCB or DHP-CCB plus thiazide-like diuretics in black patients.</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>○ Step 2: Dual full-dose combination (ACE inhibitor or ARB plus DHP-CCB); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq 80</math> years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance.</li> <li>○ Step 3: Triple combination (ACE/ARB plus DHP-CCB plus thiazide-like diuretic).</li> <li>○ Step 4, resistant hypertension: triple combination plus spironolactone or other drug, alternatives include amiloride, doxazosin, eplerenone, clonidine, or <math>\beta</math>-blocker. Caution with spironolactone or other potassium sparing diuretics when estimated GFR <math>&lt; 45</math> mL/min/1.73m<sup>2</sup> or K<sup>+</sup> <math>&gt; 4.5</math> mmol/L.</li> <li>○ Consider <math>\beta</math>-blockers at any treatment step when there is a specific indications for their use, e.g., heart failure, angina, post-MI, atrial fibrillation, or younger women planning pregnancy or pregnant.</li> </ul>
<p>Hypertension Canada: <b>2020 Guidelines for the Prevention, Diagnosis, Risk Assessment, and Treatment of Hypertension in Adults and Children (2020)</b><sup>42</sup></p>	<p><u>Indications for drug therapy for adults with hypertension without compelling indications for specific agents</u></p> <ul style="list-style-type: none"> <li>● Antihypertensive therapy should be prescribed for average diastolic blood pressure (DBP) measurements of <math>\geq 100</math> mmHg or average systolic blood pressure (SBP) measurements of <math>\geq 160</math> mmHg in patients without macrovascular target organ damage or other cardiovascular risk factors.</li> <li>● Antihypertensive therapy should be strongly considered for average DPB readings <math>\geq 90</math> mmHg or for average SBP readings <math>\geq 140</math> mmHg in the presence of macrovascular target organ damage or other independent cardiovascular risk factors.</li> <li>● For high-risk patients, aged 50 years or older, with SBP levels <math>\geq 130</math> mmHg, intensive management to target a SBP <math>&lt; 120</math> mmHg should be considered. Patient selection for intensive management is recommended and caution should be taken in certain high-risk groups.</li> </ul> <p><u>Indications for drug therapy for adults with diastolic and with or without systolic hypertension</u></p> <ul style="list-style-type: none"> <li>● Initial therapy should be with either monotherapy or single pill combination (SPC). <ul style="list-style-type: none"> <li>○ Recommended monotherapy choices are: <ul style="list-style-type: none"> <li>▪ A thiazide/thiazide-like diuretic, with longer-acting diuretics preferred;</li> <li>▪ A <math>\beta</math>-blocker (in patients <math>&lt; 60</math> years of age);</li> <li>▪ An angiotensin-converting enzyme (ACE) inhibitor (in nonblack patients);</li> <li>▪ An angiotensin receptor blocker (ARB); or</li> <li>▪ A long-acting calcium channel blocker (CCB).</li> </ul> </li> <li>○ Recommended SPC choices are those in which an ACE inhibitor is combined with a CCB, ARB with a CCB, or ACE inhibitor or ARB with a diuretic.</li> <li>○ Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> </ul> </li> <li>● Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line choices. Useful choices include a thiazide/thiazide-like diuretic or CCB with either: ACE inhibitor, ARB, or <math>\beta</math>-blocker. Caution should be exercised in combining a nondihydropyridine CCB and a <math>\beta</math>-blocker. The combination of an ACE inhibitor and an ARB is not recommended.</li> <li>● If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other antihypertensive drugs may be added.</li> <li>● Possible reasons for poor response to therapy should be considered.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated hypertension; <math>\beta</math>-blockers are not recommended as first-line therapy for uncomplicated hypertension in patients <math>\geq 60</math> years of age; and ACE inhibitors are not recommended as first-line therapy for uncomplicated hypertension in black patients. However, these agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Indications for drug therapy for adults with isolated systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be single-agent therapy with a thiazide/thiazide-like diuretic, a long-acting dihydropyridine CCB, or an ARB. If there are adverse effects, another drug from this group should be substituted. Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line options.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other classes of drugs (such as <math>\alpha</math>-blockers, ACE inhibitors, centrally acting agents, or nondihydropyridine CCBs) may be combined or substituted.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated isolated systolic hypertension; and <math>\beta</math>-blockers are not recommended as first-line therapy for isolated systolic hypertension in patients <math>\geq 60</math> years of age. However, both agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Guidelines for hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• For most hypertensive patients with CAD, an ACE inhibitor or ARB is recommended.</li> <li>• For hypertensive patients with CAD, but without coexisting systolic heart failure, the combination of an ACE inhibitor and ARB is not recommended.</li> <li>• For high-risk hypertensive patients, when combination therapy is being used, choices should be individualized. The combination of an ACE inhibitor and a dihydropyridine CCB is preferable to an ACE inhibitor and a thiazide/thiazide-like diuretic in selected patients.</li> <li>• For patients with stable angina pectoris but without previous heart failure, myocardial infarction, or coronary artery bypass surgery, either a <math>\beta</math>-blocker or CCB can be used as initial therapy.</li> <li>• Short-acting nifedipine should not be used.</li> <li>• When decreasing SBP to target levels in patients with established CAD (especially if isolated systolic hypertension is present), be cautious when the DBP is <math>\leq 60</math> mmHg because of concerns that myocardial ischemia might be exacerbated, especially in patients with left ventricular hypertrophy (LVH).</li> </ul> <p><u>Guidelines for patients with hypertension who have had a recent myocardial infarction</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should include a <math>\beta</math>-blocker as well as an ACE inhibitor.</li> <li>• An ARB can be used if the patient is intolerant of an ACE inhibitor.</li> <li>• CCBs may be used in patients after myocardial infarction when <math>\beta</math>-blockers are contraindicated or not effective. Nondihydropyridine CCBs should not be used when there is heart failure, evidenced by pulmonary congestion on examination or radiography.</li> </ul> <p><u>Treatment of hypertension in association with heart failure</u></p> <ul style="list-style-type: none"> <li>• In patients with systolic dysfunction (ejection fraction <math>&lt; 40\%</math>), ACE inhibitors and <math>\beta</math>-blockers are recommended for initial therapy. Aldosterone antagonists</li> </ul>

Clinical Guideline	Recommendations
	<p>(mineralocorticoid receptor antagonists) may be combined in treatment for patients with a recent cardiovascular hospitalization, acute myocardial infarction, elevated B-type natriuretic peptide or N-terminal pro-B-type natriuretic peptide level, or New York Heart Association (NYHA) Class II-IV symptoms. Careful monitoring for hyperkalemia is recommended when combining an aldosterone antagonist with ACE inhibitor or ARB treatment. Other diuretics are recommended as additional therapy if needed. Beyond considerations of BP control, doses of ACE inhibitors or ARBs should be titrated to those reported to be effective in trials unless adverse effects become manifest.</p> <ul style="list-style-type: none"> <li>• An ARB is recommended if ACE inhibitors are not tolerated.</li> <li>• A combination of hydralazine and isosorbide dinitrate is recommended if ACE inhibitors and ARBs are contraindicated or not tolerated.</li> <li>• For hypertensive patients whose BP is not controlled, an ARB may be combined with an ACE inhibitor and other antihypertensive drug treatment. Careful monitoring should be used if combining an ACE inhibitor and an ARB because of potential adverse effects such as hypotension, hyperkalemia, and worsening renal function. Additional therapies may also include dihydropyridine CCBs.</li> <li>• An angiotensin receptor-neprilysin inhibitor (ARNI) should be used in place of an ACE inhibitor or ARB for patients with HFrEF (&lt;40%) who remain symptomatic despite treatment with appropriate dose of guideline directed HF therapy. Eligible patients must have a serum potassium &lt;5.2 mmol/L, an eGFR <math>\geq 30</math> mL/min/1.73m<sup>2</sup> and close surveillance of serum potassium and creatinine.</li> </ul> <p><u>Treatment of hypertension in association with stroke</u></p> <ul style="list-style-type: none"> <li>• BP management in acute ischemic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> <li>• BP management after acute ischemic stroke <ul style="list-style-type: none"> <li>○ Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack.</li> <li>○ After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently &lt;140/90 mmHg.</li> <li>○ Treatment with an ACE inhibitor and thiazide/thiazide-like diuretic combination is preferred.</li> <li>○ For patients with stroke, the combination of an ACE inhibitor and ARB is not recommended.</li> </ul> </li> <li>• BP management in hemorrhagic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> </ul> <p><u>Treatment of hypertension in association with LVH</u></p> <ul style="list-style-type: none"> <li>• Hypertensive patients with LVH should be treated with antihypertensive therapy to decrease the rate of subsequent cardiovascular events.</li> <li>• The choice of initial therapy can be influenced by the presence of LVH. Initial therapy can be drug treatment using ACE inhibitors, ARBs, long-acting CCBs, or thiazide/thiazide-like diuretics. Direct arterial vasodilators such as hydralazine or minoxidil should not be used.</li> </ul> <p><u>Treatment of hypertension in association with nondiabetic chronic kidney disease</u></p> <ul style="list-style-type: none"> <li>• Individualize BP targets in patients with chronic kidney disease. Consider intensive targets (SBP &lt;120 mmHg) in appropriate patients.</li> <li>• For patients with hypertension and proteinuric chronic kidney disease (urinary protein &gt;150 mg per 24 hours or albumin to creatinine ratio &gt;30 mg/mmol), initial therapy should be an ACE inhibitor or an ARB if there is intolerance to ACE inhibitors.</li> <li>• In most cases, combination therapy with other antihypertensive agents might be needed to reach target BP levels.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• The combination of an ACE inhibitor and ARB is not recommended for patients with nonproteinuric chronic kidney disease.</li> </ul> <p><u>Treatment of hypertension in association with renovascular disease</u></p> <ul style="list-style-type: none"> <li>• Patients with hypertension attributable to atherosclerotic renal artery stenosis should be primarily medically managed because renal angioplasty and stenting offers no benefit over optimal medical therapy alone.</li> <li>• Renal artery angioplasty and stenting for atherosclerotic hemodynamically significant renal artery stenosis could be considered for patients with uncontrolled hypertension resistant to maximally tolerated pharmacotherapy, progressive renal function loss, and acute pulmonary edema.</li> <li>• Patients with confirmed renal fibromuscular dysplasia (FMD) should be referred to a hypertension specialist.</li> <li>• Renal artery angioplasty without stenting is recommended for treatment of FMD-related renal artery stenosis. Stenting is not recommended unless needed because of a periprocedural dissection. Surgical revascularization should be considered in cases of complex lesions less amendable to angioplasty, stenosis associated with complex aneurysm, and restenosis despite two unsuccessful attempts of angioplasty.</li> </ul> <p><u>Treatment of hypertension in association with diabetes mellitus</u></p> <ul style="list-style-type: none"> <li>• Persons with diabetes mellitus should be treated to attain SBP of &lt;130 mmHg and DBP of &lt;80 mmHg.</li> <li>• For persons with cardiovascular or kidney disease, including microalbuminuria, or with cardiovascular risk factors in addition to diabetes and hypertension, an ACE inhibitor or an ARB is recommended as initial therapy.</li> <li>• For persons with diabetes and hypertension not included in other guidelines in this section, appropriate choices include (in alphabetical order): ACE inhibitors, ARBs, dihydropyridine CCBs, and thiazide/thiazide-like diuretics.</li> <li>• If target BP levels are not achieved with standard-dose monotherapy, additional antihypertensive therapy should be used. For persons in whom combination therapy with an ACE inhibitor is being considered, a dihydropyridine CCB is preferable to a thiazide/thiazide-like diuretic.</li> </ul> <p><u>Resistant hypertension</u></p> <ul style="list-style-type: none"> <li>• Resistant hypertension is defined as BP above target despite three or more BP-lowering drugs at optimal doses preferably including a diuretic (and usually a renin-angiotensin-aldosterone system blocker and a CCB).</li> <li>• Accurate office and out-of-office BP measurement is essential.</li> <li>• Other reasons for apparent resistant hypertension should be eliminated before diagnosing true resistant hypertension, including nonadherence, white coat effect, and secondary hypertension.</li> <li>• Pharmacotherapy with the additional use of spironolactone, bisoprolol, doxazosin, amiloride, eplerenone, or clonidine with the baseline regimen decreases BP significantly, with the greatest BP-lowering shown with spironolactone.</li> <li>• Patients with resistant hypertension should be referred to providers with expertise in diagnosis and management of hypertension.</li> </ul> <p><u>Hypertension and pediatrics</u></p> <ul style="list-style-type: none"> <li>• BP should be measured regularly in children three years of age or older; the auscultatory method is the gold-standard at present.</li> <li>• Initial therapy should be monotherapy, with an ACE inhibitor or ARB (not first-line in black children), or a long-acting dihydropyridine CCB.</li> <li>• The treatment goal is systolic and diastolic office BP and/or ABPM &lt; 95th percentile or &lt;90<sup>th</sup> percentile in children with risk factors or target organ damage.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Complex cases should be referred to an expert in pediatric hypertension.</li> </ul> <p><u>Hypertension and pregnancy</u></p> <ul style="list-style-type: none"> <li>• Up to 7% of pregnancies are complicated by a hypertensive disorder of pregnancy, and approximately 5% of women will have chronic hypertension when they become pregnant.</li> <li>• The prevalence of hypertension in pregnancy is expected to increase with women becoming pregnant later in their reproductive years and the increasing prevalence of cardiovascular comorbidities such as increased preconception body mass index and maternal diabetes.</li> <li>• The possibility of pregnancy should be considered when managing women with hypertension who are of reproductive age.</li> <li>• Preconception counselling should be offered to all women with hypertension who are considering pregnancy.</li> <li>• ACE inhibitor and ARB therapy should be avoided before conception and during pregnancy unless there is a compelling indication for their use (i.e., proteinuric kidney disease).</li> <li>• Hypertension during pregnancy can increase the risk of adverse maternal and fetal outcomes, including an increased risk of preeclampsia, placental abruption, prematurity, small for gestational age infants, stillbirth, and maternal renal and retinal injury, thus generally requires involvement of an interdisciplinary team including obstetrical care providers.</li> <li>• Antihypertensive therapy is recommended for average SBP measurements of <math>\geq 140</math> mmHg or DBP measurements of <math>\geq 90</math> mmHg in pregnant women with chronic hypertension, gestational hypertension, or preeclampsia. Initial antihypertensive therapy should be monotherapy from the following first-line drugs: oral labetalol, oral methyldopa, long-acting oral nifedipine, or other oral <math>\beta</math>-blockers (acebutolol, metoprolol, pindolol, and propranolol). Other antihypertensive drugs can be considered as second-line drugs including: clonidine, hydralazine, and thiazide diuretics.</li> <li>• Women with severe hypertension with SBP <math>\geq 160</math> mmHg or DBP <math>\geq 110</math> mmHg in pregnancy or postpartum require urgent antihypertensive therapy because it is considered an obstetrical emergency.</li> <li>• Antihypertensive drugs used in breastfeeding women include: labetalol, methyldopa, long-acting nifedipine, enalapril, or captopril.</li> </ul>
<p>European Society of Hypertension/ European Society of Cardiology: <b>2018 Guidelines for the management of arterial hypertension (2018)</b><sup>43</sup></p>	<p><u>Treatment strategies and choice of antihypertensive drugs</u></p> <ul style="list-style-type: none"> <li>• Diuretics (including thiazides, chlorthalidone, and indapamide), <math>\beta</math>-blockers, calcium channel blocker (CCB), angiotensin-converting enzyme (ACE) inhibitors, and angiotensin receptor blockers (ARBs) are all suitable for the initiation and maintenance of antihypertensive treatment, either as monotherapy or in some combinations.</li> <li>• Some agents should be considered as the preferential choice in specific conditions because used in trials in those conditions or because of greater effectiveness in specific types of organ damage. Preferred combinations should comprise a renin-angiotensin system (RAS) blocker (either an ACE inhibitor or an ARB) with a CCB or diuretic.</li> <li>• It is recommended that beta-blockers are combined with any of the other major drug classes when there are specific clinical situations, e.g. angina, post-myocardial infarction, heart failure, or heart rate control.</li> <li>• Initiation of antihypertensive therapy with a two-drug combination may be considered in patients with markedly high baseline blood pressure (BP) or at high cardiovascular (CV) risk.</li> <li>• The combination of two antagonists of the RAS is not recommended and should be discouraged.</li> <li>• Other drug combinations should be considered and probably are beneficial in</li> </ul>

Clinical Guideline	Recommendations
	<p>proportion to the extent of BP reduction. However, combinations that have been successfully used in trials may be preferable.</p> <ul style="list-style-type: none"> <li>• Combinations of two antihypertensive drugs at fixed doses in a single tablet may be recommended and favored, because reducing the number of daily pills improves adherence, which is low in patients with hypertension. Exceptions are frail older patients and those at low risk and with grade one hypertension (particularly if systolic BP is &lt;150 mmHg).</li> <li>• It is recommended that if BP is not controlled with a three-drug combination, treatment should be increased by the addition of spironolactone or, if not tolerated, other diuretics such as amiloride or higher doses of other diuretics, a beta-blocker, or an alpha-blocker.</li> </ul> <p><u>Treatment strategies in white-coat and masked hypertension</u></p> <ul style="list-style-type: none"> <li>• In white-coat hypertensives without additional risk factors, therapeutic intervention may be limited to lifestyle changes only, but this decision should be accompanied by close follow-up.</li> <li>• In white-coat hypertensives with a higher CV risk or hypertension-mediated organ damage, drug treatment may be considered in addition to lifestyle changes.</li> <li>• In masked hypertension, both lifestyle measures and antihypertensive drug treatment should be considered, because this type of hypertension has been consistently found to have a CV risk very close to that of in- and out-of-office hypertension.</li> <li>• Antihypertensive drug up-titration should be considered in treated patients whose out-of-office BP is not controlled (i.e., masked uncontrolled hypertension), because of the high CV risk of these patients.</li> </ul> <p><u>Antihypertensive treatment strategies in the elderly</u></p> <ul style="list-style-type: none"> <li>• It is recommended that older patients (<math>\geq 65</math> years) are treated with the same recommendations in non-older patient population. In very old patients (<math>\geq 80</math> years), it may be appropriate to initiate treatment with monotherapy.</li> <li>• In all older patients, when combination therapy is used, it is recommended that this is initiated at the lowest available doses. In all older patients, and especially very old or frail patients, the possible occurrence of postural BP should be closely monitored and symptoms of possible hypotensive episodes checked by ambulatory blood pressure monitoring.</li> <li>• Unless required for concomitant diseases, loop diuretics and alpha-blockers should be avoided because of their association with injurious falls.</li> <li>• Renal function should be frequently assessed to detect possible increases in serum creatinine and reductions in estimated glomerular filtration rate (eGFR) as a result of BP-related reductions in renal perfusion.</li> <li>• When treated, BP should be lowered to a systolic value of 130 to 139 mmHg and a diastolic value of &lt;80 mmHg if tolerated. Treated values of &lt;130 mmHg should be avoided.</li> </ul> <p><u>Treatment strategies in hypertensive women</u></p> <ul style="list-style-type: none"> <li>• Hormone therapy and selective estrogen receptor modulators are not recommended and should not be used for primary or secondary prevention of CVD.</li> <li>• In women with gestational hypertension, pre-existing hypertension superimposed by gestational hypertension, or with hypertension and subclinical organ damage or symptoms, initiation of drug treatments is recommended when SBP is <math>\geq 140</math> mmHg or DBP <math>\geq 90</math> mmHg. In all other cases, initiation of drug treatment is recommended when SBP is <math>\geq 150</math> mmHg or DBP is <math>\geq 95</math> mmHg.</li> <li>• Methyldopa, labetalol, and CCBs are recommended as the drugs of choice for the treatment of hypertension in pregnancy.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• ACE inhibitors, ARBs, or direct renin inhibitors are not recommended during pregnancy.</li> <li>• SBP <math>\geq 170</math> mmHg or DBP <math>\geq 110</math> mmHg in a pregnant woman is an emergency, and admission to hospital is recommended.</li> <li>• In severe hypertension, drug treatment with intravenous (IV) labetalol, oral methyldopa, or nifedipine is recommended.</li> <li>• The recommended treatment for hypertensive crisis is IV labetalol or nicardipine and magnesium.</li> <li>• In pre-eclampsia associated with pulmonary edema, nitroglycerin given as an IV infusion is recommended.</li> <li>• In women with gestational hypertension or mild-pre-eclampsia, delivery is recommended at 37 weeks.</li> <li>• It is recommended to expedite delivery in pre-eclampsia with adverse conditions, such as visual disturbances or hemostatic disorders</li> <li>• In women at high risk of pre-eclampsia, provided they are at low risk of gastrointestinal hemorrhage, treatment with low dose aspirin from 12 weeks until delivery may be considered.</li> <li>• Methyldopa, labetalol, and nifedipine should be considered preferential antihypertensive drugs in pregnancy. Intravenous labetalol or infusion of nitroprusside should be considered in case of emergency (pre-eclampsia).</li> </ul> <p><u>Treatment strategies in patients with diabetes</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive drug treatment is recommended for people with diabetes when office BP is <math>\geq 140/90</math> mmHg.</li> <li>• A SBP goal <math>&lt; 130</math> mmHg is recommended in patients with diabetes and <math>&lt; 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg.</li> <li>• In older people, the target SBP range is 130 to 139 mmHg.</li> <li>• The DBP target in patients with diabetes is recommended to be <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• It is recommended to initiate treatment with a combination of a RAS blocker with a CCB or thiazide/thiazide-like diuretic.</li> <li>• It is recommended that individual drug choice takes comorbidities into account.</li> <li>• Simultaneous administration of two blockers of the RAS is not recommended and should be avoided in patients with diabetes.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with nephropathy</u></p> <ul style="list-style-type: none"> <li>• In patients with diabetic and non-diabetic CKD, it is recommended that an office BP of <math>\geq 140/90</math> mmHg be treated with lifestyle advice and BP-lowering medication.</li> <li>• In patients with diabetic or non-diabetic CKD, it is recommended to lower SBP to a range of 130 to 139 mmHg. And individualized treatments should be considered according to its tolerability and impact on renal function and electrolytes.</li> <li>• A combination of a RAS blocker with a CCB or a diuretic is recommended as initial therapy.</li> <li>• RAS blockers are more effective in reducing albuminuria than other antihypertensive agents, and are indicated in hypertensive patients in the presence of microalbuminuria or overt proteinuria.</li> <li>• Combination of two RAS blockers, though potentially more effective in reducing proteinuria, is not recommended.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with cerebrovascular disease</u></p> <ul style="list-style-type: none"> <li>• In patients with acute intracerebral hemorrhage, immediate BP lowering is not recommended for patients with SBP <math>&lt; 220</math> mmHg. In patients with SBP <math>\geq 220</math> mmHg, care acute BP lowering with IV therapy to <math>&lt; 180</math> mmHg should be considered.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In acute ischemic stroke, routine BP lowering with antihypertensive therapy is not recommended with the exceptions with the exceptions: in patients with acute ischemic stroke who are eligible for IV thrombolysis, BP should be carefully lowered and maintained at &lt;180/105 mmHg for at least the first 24 hours after thrombolysis; In patients with markedly elevated BP who do not receive fibrinolysis, drug therapy may be considered, based on clinical judgement, to reduce BP by 15% during the first 24 hours after the stroke onset.</li> <li>• In hypertensive patients with an acute cerebrovascular event, antihypertensive treatment is recommended immediately for transient ischemic attack (TIA) and after several days in ischemic stroke.</li> <li>• In all hypertensive patients with ischemic stroke or TIA, an SBP target range of 120 to 130 mmHg should be considered.</li> <li>• The recommended antihypertensive drug treatment strategy for stroke prevention is a RAS blocker plus a CCB or a thiazide-like diuretic.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with heart failure (HF) or left ventricular hypertrophy (LVH)</u></p> <ul style="list-style-type: none"> <li>• In hypertensive patients with heart failure (with reduced or preserved ejection fraction), BP-lowering treatment should be considered if <math>\geq 140/90</math> mmHg.</li> <li>• In patients with HFrEF, it is recommended that BP-lowering treatment comprises an ACE inhibitor or ARB, and a beta-blocker and a diuretic and/or mineralocorticoid receptor antagonist (MRA) if required.</li> <li>• Dihydropyridine CCBs may be added if BP control is not achieved.</li> <li>• In patients with HFpEF, BP treatment threshold and target values should be the same as for HFrEF).</li> <li>• Because no specific drug has proven its superiority, all major agents can be used.</li> <li>• In all patients with LVH, it is recommended to treat with a RAS blocker or in combination with a CCB or diuretic and SBP should be lowered to a range of 120 to 130 mmHg.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• In patients with CAD receiving BP-lowering drugs, it is recommended to target SBP to <math>\leq 130</math> mmHg if tolerated, but not &lt;120 mmHg. In older patients, the target is an SBP range of 130 to 140 mmHg. The target DBP is &lt;80 mmHg, but not &lt;70 mmHg.</li> <li>• In hypertensive patients with a history of myocardial infarction, beta-blockers and RAS blockers are recommended as part of treatment.</li> <li>• In patients with asymptomatic angina, beta-blockers and/or CCBs are recommended.</li> </ul>
<p>National Institute for Health and Clinical Excellence: <b>Hypertension in adults: diagnosis and management (2019)</b><sup>44</sup></p>	<p><u>Choosing antihypertensive drug treatment (for people with or without type II diabetes)</u></p> <ul style="list-style-type: none"> <li>• Where possible, recommend treatment with drugs taken only once a day.</li> <li>• Prescribe non-proprietary drugs where these are appropriate and minimize cost.</li> <li>• Offer people with isolated systolic hypertension (systolic blood pressure <math>\geq 160</math> mmHg) the same treatment as people with both raised systolic and diastolic blood pressure.</li> <li>• Offer antihypertensive drug treatment to women of child-bearing potential with diagnosed hypertension in line with recommendations in this guideline. For women considering pregnancy or who are pregnant or breastfeeding, manage hypertension in line with the recommendations on Management of pregnancy with chronic hypertension and Breastfeeding in 'Hypertension in pregnancy'.</li> <li>• When choosing antihypertensive drug treatment for adults of black African or African-Caribbean family origin, consider an angiotensin II receptor blocker, in preference to an angiotensin-converting enzyme inhibitor.</li> </ul> <p><u>Step one treatment</u></p>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Patients &lt;55 years of age should be offered a step one antihypertensive with an angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB).</li> <li>• Offer an ACE inhibitor or an ARB to adults starting step 1 antihypertensive treatment who have type II diabetes and are of any age or family origin or those aged &lt;55 years but not of black African or African-Caribbean family origin.</li> <li>• If an ACE inhibitor is not tolerated, offer an ARB.</li> <li>• Do not combine an ACE inhibitor with an ARB for the treatment of hypertension.</li> <li>• Offer a calcium channel blocker (CCB) to adults starting step 1 antihypertensive treatment who are &gt;55 years of age and do not have diabetes and are of black African or African-Caribbean family origin and do not have type II diabetes and of any age.</li> <li>• If a CCB is not suitable, for example because of edema or intolerance, or if there is evidence of heart failure or a high risk of heart failure, offer a thiazide-like diuretic.</li> <li>• If diuretic treatment is to be initiated or changed, offer a thiazide-like diuretic, such as indapamide in preference to a conventional thiazide diuretic such as bendroflumethiazide or hydrochlorothiazide.</li> <li>• For adults with hypertension who are already receiving treatment with bendroflumethiazide or hydrochlorothiazide, who have stable, well-controlled blood pressure, continue with their treatment.</li> </ul> <p><u>Step two treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering next step treatment for hypertension discuss with the person if they are taking their medicine as prescribed and support adherence in line with NICE's guideline on "Medicines adherence: involving patients decisions about prescribed medicines and supporting adherence".</li> <li>• If hypertension is not controlled with a step one treatment of an ACE inhibitor or ARB, offer choice of one of the following drugs in addition to the step one treatment: a CCB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults taking step one treatment of a CCB, offer the choice of one of the following drugs in addition to the step one treatment: an ACE inhibitor or an ARB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults of black African or African-Caribbean family origin who do not have type 2 diabetes taking step one treatment, consider an ARB, in preference to an ACE inhibitor, in addition to step one treatment.</li> </ul> <p><u>Step three treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering step three treatment, review the person's medications to ensure they are being taken at the optimal doses and discuss adherence (see recommendation under step two).</li> <li>• If hypertension is not controlled in adults taking step two treatment, offer a combination of an ACE inhibitor or ARB and a CCB and a thiazide-like diuretic.</li> </ul> <p><u>Step four treatment</u></p> <ul style="list-style-type: none"> <li>• If hypertension is not controlled in adults taking the optimal tolerated doses of an ACE inhibitor or an ARB plus a CCB and a thiazide-like diuretic, regard them as having resistant hypertension.</li> <li>• Before considering further treatment for a person with resistant hypertension, confirm elevated clinic blood pressure measurements using ambulatory or home blood pressure recordings, assess for postural hypotension, and discuss adherence.</li> <li>• For people with confirmed resistant hypertension, consider adding a fourth antihypertensive drug as step four treatment or seeking specialist advice.</li> <li>• Consider further diuretic therapy with low-dose spironolactone for adults with resistant hypertension starting step four treatment who have a blood potassium</li> </ul>

Clinical Guideline	Recommendations
	<p>level of 4.5 mmol/l or less. Use particular caution in people with a reduced estimated glomerular filtration rate because they have an increased risk of hyperkalemia.</p> <ul style="list-style-type: none"> <li>• When using further diuretic therapy for step four treatment of resistant hypertension, monitor blood sodium and potassium and renal function within one month of starting treatment and repeat as needed thereafter.</li> <li>• Consider an alpha-blocker or beta-blocker for adults with resistant hypertension starting step four treatment who have a blood potassium level of more than 4.5 mmol/l.</li> <li>• If blood pressure remains uncontrolled in people with resistant hypertension taking the optimal tolerated doses of four drugs, seek specialist advice.</li> </ul>
<p>International Society on Hypertension in Blacks: <b>Management of High Blood Pressure in Blacks (2010)</b><sup>45</sup></p>	<ul style="list-style-type: none"> <li>• To attain and maintain blood pressure (BP) below target levels, multiple antihypertensive drugs will be required in most hypertensive blacks.</li> <li>• Use of two-drug combination therapy when SBP is &gt;15 mm Hg and/or DBP is &gt;10 mm Hg above goal levels is increasingly recommended as first-line therapy.</li> <li>• Two-drug regimens have generally contained a thiazide-type diuretic; however, the combination of a calcium channel blocker (CCB) with either an ACE inhibitor or an ARB has been shown equally efficacious in BP lowering but with demonstrated superiority (CCB+ACE) for hard clinical outcomes compared with the same ACE inhibitor plus a thiazide-type diuretic.</li> <li>• In secondary prevention patients, the combination therapy should include a drug(s) with the appropriate compelling indications.</li> <li>• Certain classes of antihypertensive medications, specifically diuretics and CCBs, lower BP on average more than <math>\beta</math>-blockers and renin-angiotensin system (RAS) blockers in black patients when used as monotherapies.</li> <li>• In the absence of compelling indications, when BP is near goal levels, monotherapy with a diuretic or a CCB is preferred.</li> <li>• Lifestyle modifications should be initiated in all patients with hypertension, whether or not pharmacotherapy is planned.</li> <li>• ACE inhibitors or ARBs are recommended as alternative monotherapy options in the treatment of hypertension in blacks. The rationale for their lower tier monotherapy recommendation is because they have consistently achieved lesser average reductions in BP relative to that observed with monotherapy using either a diuretic or CCB.</li> </ul>
<p>Kidney Disease Improving Clinical Outcomes Group: <b>KDIGO Clinical Practice Guideline for the Management of Blood Pressure in Chronic Kidney Disease (2021)</b><sup>46</sup></p>	<p><u>Blood pressure measurement</u></p> <ul style="list-style-type: none"> <li>• The Work Group recommends standardized office blood pressure (BP) measurement in preference to routine office BP measurements for the management of high BP in adults.</li> <li>• The Work Group suggests that out-of-office BP measurements with ambulatory BP monitoring (ABPM) or home BP monitoring (HBPM) be used to complement standardized office BP readings for the management of high BP.</li> </ul> <p><u>Lifestyle interventions for lowering BP in patients with chronic kidney disease (CKD) not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>• The Work Group suggests targeting a sodium intake &lt;2 grams of sodium per day (or &lt;90 mmol of sodium per day, or &lt;5 grams of sodium chloride per day) in patients with high BP and CKD.</li> <li>• The Work Group suggests that patients with high BP and CKD be advised to undertake moderate-intensity physical activity for a cumulative duration of at least 150 minutes per week, or to a level compatible with their cardiovascular and physical tolerance.</li> </ul> <p><u>BP management in patients with CKD, with or without diabetes, not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>• The Work Group suggests that adults with high BP and CKD be treated with a</li> </ul>

Clinical Guideline	Recommendations
	<p>target systolic BP (SBP) of &lt;120 mmHg, when tolerated, using standardized office BP measurement.</p> <ul style="list-style-type: none"> <li>The Work Group recommends starting renin-angiotensin-system inhibitors (RASi) (angiotensin-converting enzyme inhibitor [ACEi] or angiotensin II receptor blocker [ARB]) for people with high BP, CKD, and severely increased albuminuria without diabetes.</li> <li>The Work Group suggests starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately increased albuminuria without diabetes.</li> <li>The Work Group recommends starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately-to-severely increased albuminuria with diabetes.</li> <li>The Work Group recommends avoiding any combination of ACEi, ARB, and direct renin inhibitor (DRI) therapy in patients with CKD, with or without diabetes.</li> </ul> <p><b>BP management in kidney transplant recipients</b></p> <ul style="list-style-type: none"> <li>Treat adult kidney transplant recipients with high BP to a target BP of &lt;130 mmHg systolic and &lt;80 mmHg diastolic using standardized office BP measurement.</li> <li>The Work Group recommends that a dihydropyridine calcium channel blocker (CCB) or an ARB be used as the first-line antihypertensive agent in adult kidney transplant recipients.</li> </ul> <p><b>BP management in children with CKD</b></p> <ul style="list-style-type: none"> <li>The Work Group suggests that in children with CKD, 24-hour mean arterial pressure by ABPM should be lowered to &lt;50<sup>th</sup> percentile for age, sex, and height.</li> </ul>
<p>American College of Cardiology/ American Heart Association Task Force: <b>Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults (2017)</b><sup>47</sup></p>	<p><b>Initiation of Blood Pressure (BP) Treatment for Overall Cardiovascular Disease (CVD) Risk</b></p> <ul style="list-style-type: none"> <li>Use of BP-lowering medications is recommended for secondary prevention of recurrent CVD events in patients with clinical CVD and an average systolic blood pressure (SBP) ≥130 mmHg or an average diastolic blood pressure (DBP) of ≥80 mmHg and for primary prevention in adults with an estimated 10-year atherosclerotic cardiovascular disease (ASCVD) risk of ≥10% and an average SBP of ≥130 mmHg or an average ≥80 mmHg.</li> <li>Use of BP-lowering medication is recommended for primary prevention of CVD in adults with no history of CVD and with an estimated 10-year ASCVD risk &lt;10% and an SBP of ≥140 mmHg or a DBP of ≥90 mmHg.</li> <li>Simultaneous use of an angiotensin converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), and/or renin inhibitor is potentially harmful and is not recommended to treat adults with hypertension.</li> <li>For adults with confirmed hypertension and known CVD or 10-year ASCVD risk of ≥10%, a BP target &lt;130/80 mmHg is recommended. For adults with confirmed hypertension without additional markers of increased CVD risk, a BP target &lt;130/80 mmHg may be reasonable.</li> <li>For initiation of antihypertensive drug therapy, first-line agents include thiazide diuretics, calcium channel blockers (CCBs), and ACE inhibitors or ARBs.</li> <li>Initiation of antihypertensive drug therapy with two first-line agents of different classes, either as separate agents or in a fixed-dose combination, is recommended in adults with stage 2 hypertension and an average BP &gt;20/10 mmHg above their BP target.</li> <li>Initiation of antihypertensive drug therapy with a single antihypertensive drug is reasonable in adults with stage 1 hypertension and BP goal &lt;130/80 mmHg with dosage titration and sequential addition of other agents to achieve the BP target.</li> </ul> <p><b>Stable Ischemic Heart Disease (SIHD)</b></p> <ul style="list-style-type: none"> <li>In adults with SIHD and hypertension, a BP target &lt;130/80 is recommended.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Adults with SIHD and hypertension (BP <math>\geq</math>130/80 mmHg) should be treated with medications [e.g., guideline-directed medical therapy (GDMT) beta-blockers, ACE inhibitors, or ARBs] for compelling indications [e.g., previous myocardial infarction (MI), stable angina] as first-line therapy, with the addition of other drugs (e.g., dihydropyridine CCBs, thiazide diuretics, and/or mineralocorticoid receptor antagonists) as needed to further control hypertension.</li> <li>• In adults with SIHD with angina and persistent uncontrolled hypertension, the addition of dihydropyridine CCBs to GDMT beta-blockers is recommended.</li> <li>• In adults who have had a MI or acute coronary syndrome, it is reasonable to continue GDMT beta-blockers beyond three years as long-term therapy for hypertension.</li> <li>• Beta-blockers and/or CCBs might be considered to control hypertension in patients with coronary artery disease (CAD) had an MI more than three years ago and have angina.</li> </ul> <p><u>Heart Failure</u></p> <ul style="list-style-type: none"> <li>• In adults with increased risk of HF, the optimal BP in those with hypertension should be <math>&lt;</math>130 mmHg.</li> <li>• Adults with HFrEF and hypertension should be prescribed GDMT titrated to attain a BP <math>&lt;</math>130/80 mmHg.</li> <li>• Non-dihydropyridine CCBs are not recommended in the treatment of hypertension in adults with HFrEF.</li> <li>• In adults with HFpEF who present with symptoms of volume overload, diuretics should be prescribed to control hypertension.</li> <li>• Adults with HFpEF and persistent hypertension after management of volume overload should be prescribed ACE inhibitors or ARBs and beta-blockers titrated to attain SBP <math>&lt;</math>130 mmHg.</li> </ul> <p><u>CKD</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and CKD should be treated to a BP goal <math>&lt;</math>130/80 mmHg.</li> <li>• In adults with hypertension and CKD [stage 3 or higher or stage 1 or 2 with albuminuria (<math>\geq</math>300 mg/d, or <math>\geq</math>300 mg/g albumin-to-creatinine ratio or the equivalent in the first morning void)], treatment with an ACE inhibitor is reasonable to slow kidney disease progression. Treatment with an ARB may be reasonable if an ACE inhibitor is not tolerated.</li> <li>• After kidney transplantation, it is reasonable to treat patients with hypertension to a BP goal <math>&lt;</math>130/80 mmHg and with a CCB on the basis of improved glomerular filtration rate (GFR) and kidney survival.</li> </ul> <p><u>Cerebrovascular Disease</u></p> <ul style="list-style-type: none"> <li>• In adults with intracerebral hemorrhage (ICH) who present with SBP <math>&gt;</math>220 mmHg, it is reasonable to use continuous intravenous (IV) drug infusion and close BP monitoring to lower levels. Immediate lowering of SBP to <math>&lt;</math>140 mmHg in adults with spontaneous ICH who present within six hours of the acute event and have an SBP between 150 mmHg and 220 mmHg is not of benefit to reduce death or severe disability and can be potentially harmful.</li> <li>• Adults with acute ischemic stroke and elevated BP who are eligible for treatment with IV tissue plasminogen activator (tPA) should have their BP slowly lowered to <math>&lt;</math>185/110 mmHg before thrombolytic therapy is initiated.</li> <li>• In adults with an acute ischemic stroke, BP should be <math>&lt;</math>185/110 mmHg before administration of IV tPA and should be maintained below 180/105 mmHg for at least the first 24 hours after initiation drug therapy.</li> <li>• Starting or restarting antihypertensive therapy during hospitalization in patients with BP <math>&gt;</math>140/90 mmHg who are neurologically stable is safe and reasonable to improve long-term BP control, unless contraindicated.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In patient with BP <math>\geq 220/120</math> mmHg who did not receive IV alteplase or endovascular treatment and have no comorbid conditions requiring acute antihypertensive treatment, the benefit of initiating or reinitiating treatment of hypertension within the first 48 to 72 hours is uncertain. It might be reasonable to lower BP by 15% during the first 24 hours after onset of stroke. In patients with BP <math>&lt; 220/120</math> mmHg with the same conditions, initiating or reinitiating treatment of hypertension within the first 48 to 72 hours after an acute ischemic stroke is not effective to prevent death or dependency.</li> <li>• Adults with previously treated stroke or transient ischemic attack should be restarted on antihypertensive treatment after the first few days of the index event to reduce the risk of recurrent stroke and other vascular events. Treatment with a thiazide diuretic, ACE inhibitor, or ARB, or combination treatment consisting of a thiazide diuretic plus ACE inhibitor, is useful.</li> <li>• Adults not previously treated for hypertension who experienced a stroke or transient ischemic attack and have an established BP <math>\geq 140/90</math> mmHg should be prescribed antihypertensive treatment a few days after the index event to reduce the risk of recurrent stroke and other vascular event.</li> <li>• For adults who experience a stroke or transient ischemic attack, selection of specific drugs should be individualized on the basis of patient comorbidities and agent pharmacological class.</li> <li>• For adults who experience a stroke or transient ischemic attack, a BP goal <math>&lt; 130/80</math> mmHg may be reasonable.</li> <li>• For adults with a lacunar stroke, a target SBP goal <math>&lt; 130</math> mmHg may be reasonable.</li> <li>• In adults previously untreated for hypertension who experience an ischemic stroke or transient ischemic attack and have an SBP <math>&lt; 140</math> mmHg and a DBP <math>&lt; 90</math> mmHg, the usefulness of initiating antihypertensive treatment is not well established.</li> </ul> <p><u>Peripheral Artery Disease (PAD)</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and PAD should be treated similarly to patients with hypertension without PAD.</li> </ul> <p><u>Diabetes Mellitus (DM)</u></p> <ul style="list-style-type: none"> <li>• In adults with DM and hypertension, antihypertensive drug treatment should be initiated at a BP of <math>\geq 130/80</math> mmHg with a treatment goal <math>&lt; 130/80</math> mmHg.</li> <li>• In adults with DM and hypertension, all first-line classes of antihypertensive agents (i.e., diuretics, ACE inhibitors, ARBs, and CCBs) are useful and effective.</li> <li>• In adults with DM and hypertension, ACE inhibitors or ARBs may be considered in the presence of albuminuria.</li> </ul> <p><u>Atrial Fibrillation, Valvular Heart Disease, and Aortic disease</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension can be useful for prevention of recurrence of AF.</li> <li>• In adults with asymptomatic aortic stenosis, hypertension should be treated with pharmacotherapy, starting at a low dose and gradually titrating upward as needed.</li> <li>• In patients with chronic aortic insufficiency, treatment of systolic hypertension with agents that do not slow the heart rate (i.e., avoid beta-blockers) is reasonable.</li> <li>• Beta-blockers are recommended as the preferred antihypertensive agents in patients with hypertension and thoracic aortic disease.</li> </ul> <p><u>Racial and Ethnic Differences in Treatment</u></p> <ul style="list-style-type: none"> <li>• In black adults with hypertension but without HF or CKD, including those with DM, initial antihypertensive treatment should include a thiazide-type diuretic or CCB. Two or more antihypertensive medications are recommended to achieve a BP target <math>&lt; 130/80</math> mmHg in most adults with hypertension, especially in black adults with hypertension.</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Pregnancy</u></p> <ul style="list-style-type: none"> <li>• Women with hypertension who become pregnant, or are planning to become pregnant, should be transitioned to methyldopa, nifedipine, and/or labetalol during pregnancy.</li> <li>• Women with hypertension who become pregnant should not be treated with ACE inhibitors, ARBs, or direct renin inhibitors.</li> </ul> <p><u>Older Persons</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension with an SBP treatment goal &lt;130 mmHg is recommended for noninstitutionalized ambulatory community-dwelling adults (≥65 years of age) with an average SBP of ≥130 mmHg.</li> <li>• For older adults (≥65 years of age) with hypertension and a higher burden of comorbidity and limited life expectancy, clinical judgment, patient preference, and a team-based approach to assess risk/benefit is reasonable for decisions regarding intensity of BP lowering and choice of antihypertensive drugs.</li> </ul> <p><u>Hypertensive Crises</u></p> <ul style="list-style-type: none"> <li>• In adults with a hypertensive emergency, admission to an intensive care unit is recommended for continuous monitoring of BP and target organ damage and for parenteral administration of an appropriate agent.</li> <li>• For adults with a compelling condition (i.e., aortic dissection, severe pre-eclampsia or eclampsia, or pheochromocytoma crisis), SBP should be reduced to &lt;140 mmHg during the first hour and to &lt;120 mmHg in aortic dissection.</li> <li>• For adults without a compelling condition, SBP should be reduced by no more than 25% within the first hours; then, if stable, to 160/100 mmHg within the next two to six hours; and then cautiously to normal during the following 24 to 48 hours.</li> </ul> <p><u>Cognitive Decline and Dementia</u></p> <ul style="list-style-type: none"> <li>• In adults with hypertension, BP lowering is reasonable to prevent cognitive decline and dementia.</li> </ul> <p><u>Patients Undergoing Surgical Procedures</u></p> <ul style="list-style-type: none"> <li>• In patients with hypertension undergoing major surgery who have been on beta-blockers chronically, beta-blockers should be continued.</li> <li>• In patients with hypertension undergoing planned elective major surgery, it is reasonable to continue medical therapy for hypertension until surgery.</li> <li>• In patients with hypertension undergoing major surgery, discontinuation of ACE inhibitors or ARBs perioperatively may be considered.</li> <li>• In patients with planned elective major surgery and SBP ≥180 mmHg or DBP ≥110 mmHg, deferring surgery may be considered.</li> <li>• For patients undergoing surgery, abrupt pre-operative discontinuation of beta-blockers or clonidine is potentially harmful.</li> <li>• Beta-blockers should not be started on the day of surgery in beta-blocker-naïve patients.</li> <li>• Patients with intraoperative hypertension should be managed with IV medications until such time as oral medications can be resumed.</li> </ul>
<p>American Diabetes Association: <b>Standards of Medical Care in Diabetes (2022)</b><sup>48</sup></p>	<p><u>Hypertension/blood pressure control</u></p> <ul style="list-style-type: none"> <li>• Blood pressure should be measured at every routine visit. When possible, patients found to have elevated blood pressure (≥140/90) should have blood pressure confirmed using multiple readings, including measurements on a separate day, to diagnose hypertension. Patients with blood pressure ≥180/110 and cardiovascular disease could be diagnosed with hypertension at a single visit.</li> <li>• All hypertensive patients with diabetes should monitor their blood pressure at</li> </ul>

Clinical Guideline	Recommendations
	<p>home.</p> <ul style="list-style-type: none"> <li>• For patients with diabetes and hypertension, with diabetes and hypertension, blood pressure targets should be individualized through a shared decision-making process that addresses cardiovascular risk, potential adverse effects of antihypertensive medications, and patient preferences.</li> <li>• For individuals with with diabetes and hypertension at higher cardiovascular risk (existing atherosclerotic cardiovascular disease [ASCVD] or 10-year ASCVD risk <math>\geq 15\%</math>), a blood pressure target of <math>&lt;130/80</math> mmHg may be appropriate, if it can be safely attained.</li> <li>• For individuals with diabetes and hypertension at lower risk for cardiovascular disease (10-year atherosclerotic cardiovascular disease risk <math>&lt;15\%</math>), treat to blood pressure target of <math>&lt;140/90</math>.</li> <li>• In pregnant patients with diabetes and preexisting hypertension, a blood pressure target of 110 to 135/85 is suggested in the interest of reducing the risk for accelerated maternal hypertension and minimizing impaired fetal growth.</li> <li>• For patients with blood pressure <math>&gt;120/80</math>, lifestyle intervention consists of weight loss when indicated, a Dietary Approaches to Stop Hypertension (DASH)-style eating pattern including reducing sodium and increasing potassium intake, moderation of alcohol intake, and increased physical activity.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq 140/90</math> mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of pharmacologic therapy to achieve blood pressure goals.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq 160/100</math> mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of two drugs or a single pill combination of drugs demonstrated to reduce cardiovascular events in patients with diabetes.</li> <li>• Treatment for hypertension should include drug classes demonstrated to reduce cardiovascular events in patients with diabetes (ACE inhibitors, angiotensin receptor blockers, thiazide-like diuretics, or dihydropyridine calcium channel blockers). ACE inhibitors or angiotensin receptor blockers are recommended first-line therapy for hypertension in people with diabetes and coronary artery disease.</li> <li>• Multiple-drug therapy is generally required to achieve blood pressure targets (but not a combination of ACE inhibitors and angiotensin receptor blockers).</li> <li>• An ACE inhibitor or angiotensin receptor blocker, at the maximum tolerated dose indicated for blood pressure treatment, is the recommended first-line treatment for hypertension in patients with diabetes and urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine or 30 to 299 mg/g creatinine. If one class is not tolerated, the other should be substituted.</li> <li>• For patients treated with an ACE inhibitor, angiotensin receptor blocker, or diuretic, serum creatinine/estimated glomerular filtration rate and serum potassium levels should be monitored at least annually.</li> <li>• Patients with hypertension who are not meeting blood pressure targets on three classes of antihypertensive medications (including a diuretic) should be considered for mineralocorticoid receptor antagonist therapy.</li> </ul> <p><b>Chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>• At least once a year, assess urinary albumin (e.g., spot urinary albumin-to-creatinine ratio) and estimated glomerular filtration rate in patients with type 1 diabetes with duration of five or more years and in all patients with type 2 diabetes.</li> <li>• Patients with diabetes and urinary albumin <math>\geq 300</math> mg/g creatinine and/ or an estimated glomerular filtration rate 30 to 60 mL/min/1.73 m<sup>2</sup> should be monitored twice annually to guide therapy.</li> <li>• Optimize glucose control to reduce the risk or slow the progression of chronic kidney disease (CKD).</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• For patients with type 2 diabetes and diabetic kidney disease, use of a sodium-glucose cotransporter 2 inhibitor in patients with an estimated glomerular filtration rate <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> and urinary albumin <math>\geq 300</math> mg/g creatinine is recommended to reduce CKD progression and cardiovascular events..</li> <li>• In patients with type 2 diabetes and CKD, consider use of sodium-glucose cotransporter 2 inhibitors additionally for cardiovascular risk reduction when estimated glomerular filtration rate and urinary albumin creatinine are <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> or <math>\geq 300</math> mg/g, respectively.</li> <li>• In patients with CKD who are at increased risk for cardiovascular events or CKD progression and are unable to use a sodium-glucose cotransporter 2 inhibitor, a nonsteroidal mineralocorticoid receptor antagonist (finerenone) is recommended to reduce CKD progression and cardiovascular events.</li> <li>• Optimize blood pressure control and reduce blood pressure variability to reduce the risk or slow the progression of CKD.</li> <li>• Do not discontinue renin-angiotensin system blockade for minor increases in serum creatinine (<math>\leq 30\%</math>) in the absence of volume depletion.</li> <li>• For people with nondialysis-dependent stage 3 or higher CKD, dietary protein intake should be a maximum of 0.8 g/kg body weight per day (the recommended daily allowance). For patients on dialysis, higher levels of dietary protein intake should be considered, since malnutrition is a major problem in some dialysis patients.</li> <li>• In nonpregnant patients with diabetes and hypertension, either an ACE inhibitor or an angiotensin receptor blocker is recommended for those with modestly elevated urinary albumin-to-creatinine ratio (30 to 299 mg/g creatinine) and is strongly recommended for those with urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine and/or estimated glomerular filtration rate <math>&lt; 60</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Periodically monitor serum creatinine and potassium levels for the development of increased creatinine or changes in potassium when ACE inhibitors, angiotensin receptor blockers, or diuretics are used.</li> <li>• An ACE inhibitor or an angiotensin receptor blocker is not recommended for the primary prevention of CKD in patients with diabetes who have normal blood pressure, normal urinary albumin-to-creatinine ratio (<math>&lt; 30</math> mg/g creatinine), and normal estimated glomerular filtration rate.</li> <li>• Patients should be referred for evaluation by a nephrologist if they have an estimated glomerular filtration rate <math>&lt; 30</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Promptly refer to a nephrologist for uncertainty about the etiology of kidney disease, difficult management issues, and rapidly progressing kidney disease.</li> </ul>
<p>American Academy of Family Physicians: <b>Acute Migraine Headache: Treatment Strategies (2018)</b><sup>49</sup></p>	<p><u>General treatment principles</u></p> <ul style="list-style-type: none"> <li>• Evidence-based guidelines from the United States, Canada, and Europe provide consistent recommendations, including lifestyle modifications, avoidance of triggers, and healthy coping mechanisms.</li> <li>• First-line medication options recommended for acute migraines include nonsteroidal anti-inflammatory drugs (for mild to moderate migraines) or triptans (for moderate to severe migraine).</li> <li>• The choice of triptan should be individualized based on the patient's migraine characteristics and on the route of administration, pharmacokinetics, and cost.</li> <li>• Dopamine antagonist antiemetics are second-line treatments for migraine.</li> <li>• Parenteral dihydroergotamine (DHE 45), magnesium sulfate, valproate (Depacon), and opioids should be reserved for refractory migraine because of adverse effects, weaker evidence of effectiveness, and/or abuse potential.</li> </ul>
<p>American Academy of Family Physicians: <b>Medications for Migraine</b></p>	<ul style="list-style-type: none"> <li>• Preventive therapy should be considered in patients having four or more headaches a month or at least eight headache days a month, significantly debilitating attacks despite appropriate acute management, difficulty tolerating or having a contraindication to acute therapy, medication overuse headache, patient</li> </ul>

Clinical Guideline	Recommendations
<p><b>Prophylaxis (2019)<sup>50</sup></b></p>	<p>preference, or the presence of certain migraine subtypes (i.e., hemiplegic migraine; migraine with brainstem aura; migrainous infarction; or frequent, persistent, or uncomfortable aura symptoms).</p> <ul style="list-style-type: none"> <li>• Divalproex (Depakote), topiramate (Topamax), metoprolol, propranolol, and timolol are effective for migraine prevention and should be offered as first-line treatment.</li> <li>• Petasites (an extract of the butterbur plant) has been established as effective and can be considered for migraine prevention.</li> <li>• Behavioral treatments, such as relaxation training, thermal biofeedback combined with relaxation training, electromyographic biofeedback, and cognitive behavior therapy, are effective options for migraine prevention.</li> <li>• Adding acupuncture to symptomatic treatment decreases the frequency of migraine headaches.</li> <li>• For menstrual migraines, starting preventive therapy before the time of expected migraine onset can help prevent disability and reduce severity.</li> <li>• Frovatriptan and naratriptan are recommended for menstrual-associated migraines.</li> </ul>
<p>American Academy of Neurology/ American Headache Society: <b>Evidence-based guideline update: Pharmacologic treatment for episodic migraine prevention in adults (2012)<sup>51</sup></b></p>	<ul style="list-style-type: none"> <li>• The following medications are established as effective and should be offered for migraine prevention: <ul style="list-style-type: none"> <li>○ Antiepileptic drugs (AEDs): divalproex sodium, sodium valproate, topiramate</li> <li>○ <math>\beta</math>-Blockers: metoprolol, propranolol, timolol</li> <li>○ Triptans: frovatriptan for short-term menstrually associated migraine prevention</li> </ul> </li> <li>• The following medications are probably effective and should be considered for migraine prevention: <ul style="list-style-type: none"> <li>○ Antidepressants: amitriptyline, venlafaxine</li> <li>○ <math>\beta</math>-Blockers: atenolol, nadolol</li> <li>○ Triptans: naratriptan, zolmitriptan for short-term menstrually associated migraine prevention</li> </ul> </li> </ul>
<p>European Federation of Neurological Societies: <b>Guideline on the Drug Treatment of Migraine - Revised Report of an European Federation of Neurological Societies Task Force (2009)<sup>52</sup></b></p>	<ul style="list-style-type: none"> <li>• Prophylactic drugs for the treatment of migraine with good efficacy and tolerability and evidence of efficacy are <math>\beta</math>-blockers, calcium-channel blockers, antiepileptic drugs, NSAIDs, antidepressants, and miscellaneous drugs.</li> <li>• The use of all these drugs is based on empirical data rather than on proven pathophysiological concepts.</li> <li>• There is no commonly accepted indication for starting a prophylactic treatment. Prophylactic drug treatment of migraine should be considered and discussed with the patient when 1) the quality of life, business duties, or school attendance are severely impaired; 2) frequency of attacks per month is two or higher; 3) migraine attacks do not respond to acute drug treatment; or 4) frequent, very long, or uncomfortable auras occur.</li> <li>• The recommended drugs of first choice are <math>\beta</math>-blockers (metoprolol or propranolol), calcium-channel blockers (flunarizine), and antiepileptic drugs (valproic acid or topiramate).</li> <li>• Drugs of second choice include amitriptyline, venlafaxine, naproxen, and bisoprolol.</li> <li>• Drugs of third choice include acetylsalicylic acid, gabapentin, magnesium, riboflavin, coenzyme Q10, candesartan, lisinopril, and methylsergide.</li> <li>• <math>\beta</math>-blockers are clearly effective in migraine prophylaxis and very well studied. The best evidence has been obtained for metoprolol and propranolol. Bisoprolol, timolol and atenolol might be effective, but evidence is less convincing compared with propranolol and metoprolol.</li> <li>• The calcium-channel blocker, flunarizine, has been shown to be effective in migraine prophylaxis in several studies.</li> <li>• Valproic acid and topiramate are two antiepileptic drugs with evidence of efficacy in more than one placebo-controlled trial. The efficacy rates are comparable to</li> </ul>

Clinical Guideline	Recommendations
	<p>those of metoprolol, propranolol, and flunarizine. Topiramate is also efficacious in the prophylaxis of chronic migraine and may have some effect in migraine with medication overuse.</p>
<p>National Cancer Institute: <b>Pheochromocytoma and Paraganglioma Treatment (PDQ®) (2021)</b><sup>53</sup></p>	<p><b>Preoperative Medical Preparation</b></p> <ul style="list-style-type: none"> <li>• Surgery is the mainstay of treatment for most patients; however, preoperative medical preparation is critical. <math>\alpha</math>-adrenergic blockade should be initiated at the time of diagnosis and maximized preoperatively to prevent potentially life-threatening cardiovascular complications, which can occur as a result of excess catecholamine secretion during surgery. Complications may include hypertensive crisis, arrhythmia, myocardial infarction, and pulmonary edema.</li> <li>• Phenoxybenzamine (a nonselective <math>\alpha</math>-antagonist) is the usual drug of choice; prazosin, terazosin, and doxazosin (selective <math>\alpha</math>-1-antagonists) are alternative choices. Prazosin, terazosin, and doxazosin are shorter acting than phenoxybenzamine, and therefore, the duration of postoperative hypotension is theoretically less than with phenoxybenzamine; however, there is less overall experience with selective <math>\alpha</math>-1-antagonists than with phenoxybenzamine.</li> <li>• A preoperative treatment period of one to three weeks is usually sufficient.</li> <li>• Resolution of spells and a target low normal blood pressure for age indicate that <math>\alpha</math>-adrenergic blockade is adequate.</li> <li>• During <math>\alpha</math>-adrenergic blockade, liberal salt and fluid intake should be encouraged because volume loading reduces excessive orthostatic hypotension both preoperatively and postoperatively.</li> <li>• If tachycardia develops or if blood pressure control is not optimal with <math>\alpha</math>-adrenergic blockade, a <math>\beta</math>-blocker (e.g., metoprolol or propranolol) can be added, but only after <math>\alpha</math>-blockade.</li> <li>• A <math>\beta</math>-adrenergic blockade must never be initiated before <math>\alpha</math>-blockade; doing so blocks <math>\beta</math>-blocker mediated vasodilation and results in unopposed <math>\alpha</math>-blocker receptor mediated vasoconstriction, which can lead to a life-threatening crisis.</li> </ul> <p><b>Localized Pheochromocytoma Treatment</b></p> <ul style="list-style-type: none"> <li>• The standard treatment option for patients with localized pheochromocytoma is surgery.</li> <li>• Intraoperative hypertension can be controlled with intravenous infusion of phentolamine, sodium nitroprusside, or a short-acting calcium-channel blocker (e.g., nicardipine).</li> <li>• Tumor removal may be followed by a sudden drop in blood pressure that may require rapid volume replacement and intravenous vasoconstrictors (e.g., norepinephrine or phenylephrine).</li> <li>• Postoperatively, patients should remain in a monitored environment for 24 hours.</li> <li>• Postoperative hypotension is managed primarily by volume expansion, and postoperative hypertension usually responds to diuretics.</li> </ul> <p><b>Pheochromocytoma During Pregnancy</b></p> <ul style="list-style-type: none"> <li>• Phenoxybenzamine use is safe in pregnancy, but beta-adrenergic blockers should be initiated only if needed because their use has been associated with intrauterine growth restriction.</li> </ul>
<p>American Academy of Neurology: <b>Practice Parameter: Therapies for Essential Tremor: Report of the Quality Standards Subcommittee of the American Academy</b></p>	<ul style="list-style-type: none"> <li>• Propranolol and primidone are agents that are most commonly used to treat essential tremor (ET).</li> <li>• It is recommended that propranolol, long-acting propranolol, or primidone be offered to patients who want treatment for limb tremor in ET, depending on concurrent medical conditions and potential side effects.</li> <li>• It is recommended that either primidone or propranolol be used as initial therapy to treat limb tremor in ET.</li> <li>• It is recommended that atenolol and sotalol be considered for treatment of limb tremor associated with ET, and propranolol may be considered as a treatment</li> </ul>

Clinical Guideline	Recommendations
<p><b>of Neurology (2005)<sup>54</sup>, Evidence-based guideline update: Treatment of essential tremor (2011 update)<sup>55</sup></b></p> <p><b>Reaffirmed April 2017</b></p>	<p>option for head tremor in patients with ET.</p> <ul style="list-style-type: none"> <li>• Nadolol may be considered a treatment option for limb tremor associated with ET.</li> <li>• Pindolol is not recommended for treatment of limb tremor in ET.</li> <li>• Due to the lack of evidence, a recommendation regarding the use of metoprolol in the treatment of limb tremor in ET cannot be provided.</li> <li>• The combination of primidone and propranolol may be used to treat limb tremor when the use of a single agent does not adequately decrease tremor.</li> <li>• The dosages of propranolol and primidone may need to be increased after 12 months of therapy when treating limb tremor in ET.</li> <li>• Levetiracetam and 3,4-diaminopyridine should not be considered for treatment of limb tremor in ET.</li> <li>• Clinicians may choose not to consider flunarizine for treatment of limb tremor in ET.</li> <li>• The evidence is insufficient to make recommendations regarding the use of pregabalin, zonisamide, or clozapine</li> </ul>
<p>American Academy of Pediatrics: <b>Clinical Practice Guideline for the Management of Infantile Hemangiomas (2019)<sup>56</sup></b></p>	<p><u>Pharmacotherapy</u></p> <ul style="list-style-type: none"> <li>• Clinicians should use oral propranolol as the first-line agent for Infantile Hemangiomas (IHs) requiring systemic treatment (grade A, strong recommendation)</li> <li>• Clinicians should dose propranolol between 2 and 3 mg/kg per day unless there are comorbidities (e.g., PHACE syndrome) or adverse effects (e.g., sleep disturbance) that necessitate a lower dose (grade A, moderate recommendation).</li> <li>• Clinicians should counsel that propranolol be administered with or after feeding and that doses be held at times of diminished oral intake or vomiting to reduce the risk of hypoglycemia (grade X, strong recommendation)</li> <li>• Clinicians should evaluate patients for and educate caregivers about potential adverse effects of propranolol, including sleep disturbances, bronchial irritation, and clinically symptomatic bradycardia and hypotension (grade X, strong recommendation)</li> <li>• Clinicians may prescribe oral prednisolone or prednisone to treat IHs if there are contraindications or an inadequate response to oral propranolol (grade B, moderate recommendation).</li> <li>• Clinicians may recommend intralesional injection of triamcinolone and/or betamethasone to treat focal, bulky IHs during proliferation or in certain critical anatomic locations (e.g., the lip) (grade B, moderate recommendation)</li> <li>• Clinicians may prescribe topical timolol maleate as a therapy for thin and/or superficial IHs (grade B, moderate recommendation).</li> <li>• Clinicians may recommend surgery and laser therapy as treatment options in managing selected IHs (grade C, moderate recommendation)</li> <li>• Clinicians should educate parents of infants with an IH about the condition, including the expected natural history, and its potential for causing complications or disfigurement (grade X, strong recommendation).Clinicians should educate parents of infants with an IH about the condition, including the expected natural history, and its potential for causing complications or disfigurement (grade X, strong recommendation).</li> </ul>

\*Agent not available in the United States.

### III. Indications

The Food and Drug Administration (FDA)-approved indications for the  $\beta$ -adrenergic blocking agents are noted in Tables 4 and 5. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 4. FDA-Approved Indications for the Beta-Adrenergic Blocking Agents<sup>3-22</sup>**

Indications	Single Entity Agents (A-N)								
	Acebutolol	Atenolol	Betaxolol	Bisoprolol	Carvedilol	Labetalol	Metoprolol	Nadolol	Nebivolol
<b>Angina Pectoris</b>									
Long-term management of angina pectoris		✓ *					✓ †	✓	
<b>Cardiac Arrhythmias</b>									
Management of ventricular premature beats	✓								
<b>Heart Failure</b>									
Mild to severe chronic heart failure of ischemic or cardiomyopathic origin to increase survival and, also, to reduce the risk of hospitalizations					✓				
Stable, symptomatic (NYHA Class II or III) heart failure of ischemic, hypertensive, or cardiomyopathic origin							✓ (succinate)		
<b>Hypertension</b>									
Control of blood pressure in severe hypertension						✓ (injection)			
Hypertension	✓ ‡	✓ ‡	✓ ‡	✓ ‡	✓ ‡	✓ ‡ (tablet)	✓ ‡	✓ ‡	✓ ‡
<b>Myocardial Infarction</b>									
Hemodynamically stable patients with definite or suspected acute myocardial infarction to reduce cardiovascular mortality		✓					✓ (tartrate)		
Reduce cardiovascular mortality in clinically stable patients who have survived the acute phase of a myocardial infarction and have a left ventricular ejection fraction of $\leq 40\%$ (with or without symptomatic heart failure)					✓				

\*Due to coronary atherosclerosis.

†Metoprolol succinate: To reduce angina attacks and to improve exercise tolerance.

‡May be used in combination with other antihypertensive agents.

NYHA=New York Heart Association

**Table 5. FDA-Approved Indications for the Beta-Adrenergic Blocking Agents (continued)<sup>3-22</sup>**

Indications	Single Entity Agents (O-Z)					Combination Products				
	Penbutolol	Pindolol	Propranolol	Sotalol	Timolol	Atenolol and Chlor-thalidone	Bisoprolol and HCTZ	Metoprolol and HCTZ	Nadolol and Bendroflu-methiazide	
<b>Angina Pectoris</b>										
Angina pectoris			✓ * (Inderal LA <sup>®</sup> , tablet)							
<b>Cardiac Arrhythmias</b>										
Abolish tachyarrhythmias due to			✓							

Indications	Single Entity Agents (O-Z)					Combination Products				
	Penbutolol	Pindolol	Propranolol	Sotalol	Timolol	Atenolol and Chlor-thalidone	Bisoprolol and HCTZ	Metoprolol and HCTZ	Nadolol and Bendroflu-methiazide	
excessive catecholamine action during anesthesia when other measure fail			(injection)							
Control ventricular rate in patients with atrial fibrillation and a rapid ventricular response			✓ (tablet)							
Control ventricular rate in life-threatening digitalis-induced arrhythmias			✓ (injection)							
Documented ventricular arrhythmias, such as sustained ventricular tachycardia, that in the judgement of the physician are life-threatening				✓ † (Betapace®, Sotylize®)						
Maintenance of normal sinus rhythm in patients with symptomatic atrial fibrillation/atrial flutter who are currently in sinus rhythm				✓ † (Betapace AF®, Sotylize®)						
Persistent premature ventricular extrasystoles that impair the well-being of the patient and do not respond to conventional measures			✓ (injection)							
Short-term treatment of supraventricular tachycardia, including Wolff-Parkinson-White syndrome and thyrotoxicosis, to decrease ventricular rate			✓ (injection)							
<b>Hypertension</b>										
Hypertension		✓ ‡	✓ ‡ (oral§)		‡	✓	✓	✓ ¶	✓	
Mild to moderate arterial hypertension	✓ ‡									
<b>Hypertrophic Subaortic Stenosis</b>										
Improves NYHA functional class in symptomatic patients with hypertrophic subaortic stenosis			✓ (Inderal LA®, tablet)							
<b>Myocardial Infarction</b>										
Reduce cardiovascular mortality in patients who have survived the acute phase of myocardial infarction and are clinically stable			✓ (tablet)							
Reduce cardiovascular mortality and reinfarction in patients who have survived the acute phase of myocardial infarction and are clinically stable					✓					
<b>Other</b>										
Adjunct to $\alpha$ -adrenergic blockade to control blood pressure and reduce			✓ (tablet)							

Indications	Single Entity Agents (O-Z)					Combination Products				
	Penbutolol	Pindolol	Propranolol	Sotalol	Timolol	Atenolol and Chlor-thalidone	Bisoprolol and HCTZ	Metoprolol and HCTZ	Nadolol and Bendroflu-methiazide	
symptoms of catecholamine-secreting tumors										
Familial or hereditary essential tremor			✓ (tablet)							
Treatment of proliferating infantile hemangioma requiring systemic therapy			✓ (Hemangeol®)							
Prophylaxis of migraine headache			✓ (Inderal LA®, tablet)		✓					

\*Angina pectoris due to coronary atherosclerosis to decrease angina frequency and increase exercise tolerance.

†Intravenous sotalol can substitute for oral sotalol in patients who are unable to take sotalol orally.

‡May be used in combination with other antihypertensive agents.

§Inderal LA® and propranolol tablet are not indicated in the management of hypertensive emergencies.

|| Not indicated for initial treatment of hypertension.

¶Dutoprol® may be used in combination with other antihypertensive agents. Lopressor HCT® is not indicated for initial treatment of hypertension.

HCTZ=hydrochlorothiazide, NYHA=New York Heart Association

#### IV. Pharmacokinetics

The pharmacokinetic parameters of the  $\beta$ -adrenergic blocking agents are listed in Table 6. The lipophilic properties vary among the agents. The higher the lipid solubility, the higher the potential to cross the blood brain barrier and increase the risk of central nervous system adverse events, including dizziness and drowsiness.<sup>32,34</sup>

**Table 6. Pharmacokinetic Parameters of the Beta-Adrenergic Blocking Agents<sup>2</sup>**

Generic Name(s)	Bio-availability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life (hours)	Lipid Solubility
<b>Single Entity Agents</b>						
Acebutolol	40	10 to 26	Liver (% not reported)	Renal (30 to 40) Bile (3 to 8) Feces (56)	3 to 4	Low
Atenolol	46 to 60	6 to 16	Not reported	Renal (40 to 50) Feces (50)	6 to 7	Low
Betaxolol	78 to 90	50 to 60	Liver, extensive (% not reported)	Renal (>80)	14 to 22	Low
Bisoprolol	80 to 94	30 to 36	Liver (50)	Renal (50) Feces (<2)	9 to 12	Low
Carvedilol	21 to 35	95 to 98	Liver, extensive (% not reported)	Renal (16) Feces (60)	7 to 10	Moderate
Labetalol	25	50	Liver, extensive (% not reported)	Renal (55 to 60) Feces (50)	5 to 8	Moderate
Metoprolol	50 to 77	12	Liver, extensive (% not reported)	Renal (95)	3 to 7	Moderate
Nadolol	20 to 40	28 to 30	None	Renal (25) Feces (77)	20 to 24	Low
Nebivolol	12 to 96	98	Liver, extensive (% not reported)	Renal (<1) Feces (13 to 44)	12 to 19	High
Penbutolol	100	80 to 98	Liver, extensive (% not reported)	Renal (90)	5	High
Pindolol	95	40 to 60	Liver (60 to 65)	Renal (35 to 40) Feces (6 to 9)	3 to 4	Moderate
Propranolol	30 to 70	93	Liver (50 to 70)	Renal (<1)	3 to 6	High
Sotalol	90 to 100	0	Liver, minor	Renal (66 to 88)	7 to 12	Low
Timolol	61	<10	Liver (80)	Renal (20)	2 to 4	Low-Moderate
<b>Combination Products</b>						
Atenolol and chlorthalidone	50/65	16/75	Not reported/ Liver (% not reported)	Renal (40 to 50) Feces (50)/ Renal (60)	6 to 7/ 40 to 60	Low/not reported
Bisoprolol and HCTZ	80/ 50 to 75	30/ 40 to 68	Liver (50)/ not reported	Renal (50) Feces (<2)/ Renal (>95)	9 to 12/ 6 to 15	Low/not reported
Metoprolol and HCTZ	Not reported	12/68	Liver, extensive (% not reported)/ not reported	Renal (95)/ Renal (72 to 97)	3 to 7/ 10 to 17	Moderate/ not reported
Nadolol and bendro-flumethiazide	30	Not reported	Not Reported	Not reported	20 to 24/ 3	Not reported

HCTZ=hydrochlorothiazide

## V. Drug Interactions

Major drug interactions with the beta-adrenergic blocking agents ( $\beta$ -blockers) are listed in Table 7.

**Table 7. Major Drug Interactions with the Beta-Adrenergic Blocking Agents<sup>2</sup>**

Generic Name(s)	Interaction	Mechanism
$\beta$ -blockers (acebutolol, atenolol, betaxolol, bisoprolol, carvedilol, metoprolol, nadolol, nebivolol, penbutolol, pindolol, propranolol, sotalol, timolol)	Verapamil	May be synergistic or additive effects. Verapamil may inhibit oxidative metabolism of certain $\beta$ -blockers. Additive QT interval prolongation is possible with sotalol.
$\beta$ -blockers (nadolol, penbutolol, pindolol, propranolol, sotalol, timolol)	Epinephrine	Nonselective $\beta$ blockade allows $\alpha$ -receptor effects of epinephrine to predominate. Increasing vascular resistance leads to a rise in blood pressure and reflex bradycardia.
$\beta$ -blockers (nadolol, penbutolol, pindolol, propranolol, sotalol, timolol)	Sympathomimetics	Nonselective $\beta$ -blockers may block the action of beta-agonists, potentially resulting in severe bronchospasm in asthmatics.
Thiazides (hydrochlorothiazide, chlorthalidone, bendroflumethiazide)	Lithium	Decreased lithium clearance may occur with thiazide use. This may lead to increased serum lithium levels and possibly lithium toxicity. Monitor plasma lithium levels and symptoms of toxicity, and adjust the dose as needed.
Thiazides (hydrochlorothiazide, bendroflumethiazide)	Dofetilide	Thiazide diuretics may induce hypokalemia which may increase the risk of torsades de pointes. The coadministration of dofetilide with a thiazide diuretic is contraindicated.
$\beta$ -blockers (sotalol)	Bepiridil	Arrhythmias resulting from the potential for additive QT prolongation should be considered as a possibility.
$\beta$ -blockers (sotalol)	Chloroquine	Prolonged QT interval and cardiac arrhythmias are a potential when sotalol and chloroquine are coadministered.
$\beta$ -blockers (sotalol)	Class IA, IC, III Antiarrhythmic Agents	Class IA, IC, and III antiarrhythmics and sotalol may cause additive pharmacologic and adverse cardiovascular effects when co- administered.
$\beta$ -blockers (sotalol)	Dofetilide	The risk of cardiovascular toxicity, including torsades de pointes, may be increased by co-administration of dofetilide and sotalol. Pharmacologic effects of dofetilide and sotalol on electrical conduction of the heart may be additive.
$\beta$ -blockers (sotalol)	Dronedarone	Arrhythmias resulting from the potential for additive QT prolongation should be considered as a possibility.
$\beta$ -blockers (sotalol)	Droperidol	Arrhythmias resulting from the potential for additive QT prolongation should be considered as a possibility.
$\beta$ -blockers (sotalol)	Fluconazole	Coadministration of fluconazole and sotalol may increase the risk of potentially fatal cardiac arrhythmias (torsades de pointes), especially in seriously ill patients and/or patients receiving high dose fluconazole.
$\beta$ -blockers (sotalol)	Haloperidol	Arrhythmias resulting from the potential for additive QT prolongation should be considered as a possibility.

Generic Name(s)	Interaction	Mechanism
β-blockers (sotalol)	Maprotiline	Arrhythmias resulting from the potential for additive QT prolongation should be considered as a possibility.
β-blockers (sotalol)	Methadone	Prolongation of the QT interval with possible development of cardiac arrhythmias, including torsades de pointes, should be considered when sotalol is co-administered with methadone.
β-blockers (sotalol)	Nilotinib	Additive QT prolongation may occur during coadministration of nilotinib and sotalol.
β-blockers (sotalol)	Pentamidine	Prolongation of the QT interval with possible development of cardiac arrhythmias, including torsades de pointes, should be considered when sotalol is co-administered with pentamidine.
β-blockers (sotalol)	Perflutren	Additive QT interval prolongation may occur during coadministration of perflutren and sotalol.
β-blockers (sotalol)	Phenothiazines	Arrhythmias resulting from the potential for additive QT prolongation should be considered as a possibility when sotalol and phenothiazines are co-administered.
β-blockers (sotalol)	Phosphodiesterase type 5 Inhibitors	Phosphodiesterase type 5 inhibitors and sotalol may cause additive adverse effects when co-administered. Prolonged QT interval with the potential for cardiac arrhythmias may occur.
β-blockers (sotalol)	Pimozide	Sotalol and pimozide may cause additive adverse effects when co-administered. Cardiovascular toxicity, including torsades de pointes, may occur due to additive QT-interval prolongation.
β-blockers (sotalol)	Quinolones	The rare occurrence of arrhythmias resulting from the potential for additive QT prolongation should be considered as a possibility.
β-blockers (sotalol)	Serotonin Receptor Antagonists Antiemetics	The risk of QT-interval prolongation and cardiac arrhythmias caused by serotonin receptor antagonist antiemetics may be increased by co-administration of sotalol.
β-blockers (sotalol)	Tetrabenazine	Additive QT prolongation may occur during coadministration of tetrabenazine and sotalol.
β-blockers (sotalol)	Tyrosine Kinase Receptor Inhibitor	Additive QT interval prolongation is a possibility when tyrosine kinase receptor inhibitors are coadministered with sotalol.
β-blockers (sotalol)	Ziprasidone	Arrhythmias resulting from the potential for additive QT prolongation should be considered as a possibility when sotalol and ziprasidone are co-administered.
β-blockers (acebutolol, atenolol, betaxolol, bisoprolol, metoprolol, nadolol, nebivolol, penbutolol, pindolol, propranolol, sotalol, timolol)	Clonidine	B-blocker inhibition of β <sub>2</sub> receptor mediated vasodilation leaves peripheral α <sub>2</sub> -receptor mediated vasoconstriction unopposed to clonidine stimulation.
β-blockers (acebutolol, atenolol, betaxolol, carvedilol, metoprolol, nadolol, nebivolol, penbutolol, pindolol, propranolol, sotalol, timolol)	Diltiazem	Additive AV nodal blockade may lead to synergistic bradycardia
β-blockers (acebutolol, atenolol, betaxolol, bisoprolol, carvedilol,	Flecainide	Unknown mechanism. Combination may result in additive bradycardia and cardiac arrest

Generic Name(s)	Interaction	Mechanism
metoprolol, nadolol, nebivolol, penbutolol, pindolol, propranolol, timolol)		
β-blockers (acebutolol, atenolol, betaxolol, carvedilol, metoprolol, nadolol, nebivolol, penbutolol, pindolol, propranolol, sotalol, timolol)	Nonsteroidal Anti-inflammatory Drugs	NSAIDs may inhibit renal prostaglandin synthesis, allowing unopposed pressor systems to produce hypertension.
β-blockers (acebutolol, atenolol, betaxolol, carvedilol, metoprolol, nadolol, nebivolol, penbutolol, pindolol, propranolol, sotalol, timolol)	Quinazolines	Unknown mechanism. Additive vasodilation may increase risk of hypotension, specifically orthostatic hypotension. Generally occurs with the addition of prazosin to chronic β-blocker therapy, not β-blocker added to chronic prazosin therapy
β-blockers (bisoprolol, carvedilol, nadolol, penbutolol, pindolol, propranolol, sotalol, timolol)	Insulin	β-blockers blunt sympathetic mediated responses to hypoglycemia.
β-blockers (atenolol, carvedilol, metoprolol, nadolol, pindolol, propranolol, sotalol)	Lidocaine	Reduced hepatic lidocaine metabolism and possibly a minor component of diminished hepatic blood flow.
β-blockers (bisoprolol, carvedilol, metoprolol, pindolol, propranolol, timolol)	Cimetidine	Cimetidine may reduce hepatic first-pass extraction, decrease liver blood flow, and inhibit hepatic metabolism of β-blockers.
β-blockers (nadolol, penbutolol, pindolol, propranolol, sotalol, timolol)	Meglitinides	Unknown mechanism. Possible increase in hypoglycemic activity of meglitinides.
β-blockers (nadolol, penbutolol, pindolol, propranolol, sotalol, timolol)	Theophyllines	Pharmacologic antagonism. B-blockers may reduce the n-demethylation of theophylline.
β-blockers (atenolol, carvedilol, metoprolol, propranolol, timolol)	Quinidine	Oxidative metabolism of certain β-blockers may be inhibited by quinidine.
β-blockers (carvedilol, metoprolol, nebivolol, propranolol, timolol)	Terbinafine	Terbinafine inhibits CYP2D6 and may result in increased plasma concentrations of certain β-blockers.
β-blockers (carvedilol, metoprolol, propranolol, timolol)	Diphenhydramine	Inhibition of CYP2D6-mediated β-blocker metabolism may decrease the metabolism of certain β-blockers resulting in excessive cardiovascular effects.
β-blockers (metoprolol, nebivolol, propranolol, timolol)	Serotonin Reuptake Inhibitors	Inhibition of CYP2D6 enzyme may decrease the metabolism of metoprolol resulting in excessive pharmacologic activity.
β-blockers (metoprolol, propranolol, sotalol)	Amiodarone	Additive pharmacologic effects of both drugs may result in severe bradycardia, hypotension, or cardiac arrest. Possible additive QT interval prolongation with sotalol and amiodarone.
β-blockers (pindolol, propranolol, sotalol)	Phenothiazines	Chlorpromazine may inhibit the first-pass hepatic metabolism of propranolol and increase its pharmacologic effects. Certain β-blockers may inhibit the metabolism of phenothiazines increasing the risk for cardiac side effects, including torsades

Generic Name(s)	Interaction	Mechanism
		de pointes.
$\beta$ -blockers (carvedilol, metoprolol, propranolol)	Rifamycins (rifabutin, rifampin, rifapentine)	Possible decrease in oral bioavailability of carvedilol resulting in first-pass metabolism.
$\beta$ -blockers (carvedilol, metoprolol, propranolol)	Thiamines	Hyperthyroidism appears to cause increased clearance of $\beta$ -blockers with a high extraction ration. This may be the result of increased liver blood flow, first-pass metabolism and volume of distribution.
Thiazide diuretics (HCTZ, chlorthalidone, bendroflumethiazide)	Diazoxide	The combination of diazoxide with a thiazide diuretic may lead to hyperglycemia though an unknown mechanism; therefore the combination should be avoided. When used together, blood and urine glucose levels should be frequently monitored, and dosage reductions may be required.
Thiazide diuretics (HCTZ, chlorthalidone, bendroflumethiazide)	Digitalis glycosides	Thiazide diuretics may induce electrolyte disturbances which may predispose patients to digitalis-induced arrhythmias. Measure plasma levels of potassium and magnesium, supplement low levels, and use dietary sodium restriction or potassium-sparing diuretics to prevent further losses.
$\beta$ -blockers (metoprolol, propranolol)	Hydralazine	Hydralazine increases systemic availability of some $\beta$ -blockers, probably by transient increase in splanchnic blood flow and decreasing first-pass hepatic metabolism.
$\beta$ -blockers (metoprolol, propranolol)	Propafenone	Propafenone increases plasma $\beta$ -blocker level by decreasing first-pass metabolism and reducing systemic clearance. Both drugs are oxidized by the hepatic CYP450 system, and propafenone appears to inhibit the metabolism of the $\beta$ -blocker.
$\beta$ -blockers (atenolol)	Ampicillin	The bioavailability of atenolol may be decreased by impaired gastrointestinal absorption induced by ampicillin.
$\beta$ -blockers (carvedilol)	Cyclosporine	Unknown mechanism. Carvedilol may increase plasma concentrations of cyclosporine and dose reduction may be required.
$\beta$ -blockers (carvedilol)	Digoxin	Carvedilol may increase digoxin bioavailability. Possible additive depression of myocardial conduction and decreased renal tubular digoxin secretion.
$\beta$ -blockers (labetalol)	Inhalation anesthetics	Additive myocardial depressant effects possibly resulting in excessive hypotension.
$\beta$ -blockers (propranolol)	Mefloquine	Additive slowing of cardiac conduction possibly resulting in lengthening of the QT interval
$\beta$ -blockers (propranolol)	Triptans	Unknown mechanism. Possible inhibition of triptan metabolism (monoamine oxidase-A) by propranolol resulting in enhanced pharmacologic effects and plasma concentrations.
$\beta$ -blockers (sotalol)	Cisapride	Prolongation of the QT interval with possible development of cardiac arrhythmias, including torsades de pointes, should be considered when cisapride is co-administered with sotalol.
$\beta$ -blockers (sotalol)	H1 Antagonists	The rare occurrence of arrhythmias resulting from the potential for additive QT prolongation should

Generic Name(s)	Interaction	Mechanism
		be considered as a possibility when sotalol and H-1 antagonists are coadministered.
β-blockers (sotalol)	Iloperidone	Prolonged QT interval and cardiac arrhythmias are a potential when sotalol and iloperidone are used concomitantly.
β-blockers (sotalol)	Macrolides	The rare occurrence of arrhythmias resulting from the potential for additive QT prolongation should be considered as a possibility when sotalol and macrolides are coadministered.
β-blockers (sotalol)	Mefloquine	Co-administration of mefloquine and sotalol may cause cardiovascular toxicity, including electrocardiographic abnormalities such as QT interval prolongation
β-blockers (sotalol)	Mibefradil	Co-administration of sotalol and mibefradil may cause cardiovascular toxicity.
β-blockers (sotalol)	Paliperidone	Prolongation of the QT interval with possible development of cardiac arrhythmias, including torsades de pointes, should be considered when paliperidone is co-administered with sotalol.
β-blockers (sotalol)	Propafenone	The rare occurrence of arrhythmias resulting from the potential for additive QT prolongation should be considered when sotalol and propafenone are coadministered.
β-blockers (sotalol)	Saquinavir	Coadministration of sotalol with saquinavir/ritonavir may be associated arrhythmias due to potential additive effects on prolongation of the QT interval.
β-blockers (sotalol)	Tricyclic Antidepressants	The rare occurrence of arrhythmias resulting from the potential for additive QT prolongation should be considered as a possibility when tricyclic antidepressants and sotalol are coadministered.
β-blockers (acebutolol)	Ceritinib	Bradycardia causing agents may enhance the bradycardic effect of ceritinib.
β-blockers (acebutolol, atenolol, betaxolol, bisoprolol, carvedilol, labetalol, metoprolol, nadolol, nebivolol, pindolol, propranolol, timolol)	Rivastigmine	Concurrent use may result in additive bradycardic effects.
β-blockers (carvedilol, labetalol, nadolol, pindolol, propranolol, timolol)	Beta2-agonists (non-selective)	Nonselective beta-blockers may diminish the bronchodilatory effect of beta2-agonists
β-blockers (carvedilol)	Topotecan	P-glycoprotein/ABCB1 inhibitors may increase the serum concentration of topotecan
β-blockers (carvedilol)	Vincristine	P-glycoprotein/ABCB1 inhibitors may increase the serum concentration of vincristine
β-blockers (pindolol, propranolol, sotalol)	Thioridazine	Concurrent use may result in increased risk of thioridazine toxicity (e.g., QT prolongation, torsades de pointes, cardiac arrest)
β-blockers (sotalol)	Fingolimod	Concurrent use may result in increased risk of QT interval prolongation, bradycardia, or heart block

CYP=cytochrome P450 isoenzymes, HCTZ=hydrochlorothiazide

## VI. Adverse Drug Events

The most common adverse drug events reported with the  $\beta$ -adrenergic blocking agents are listed in Tables 8 and 9. The boxed warnings for the  $\beta$ -adrenergic blocking agents are listed in Tables 10 through 15.

**Table 8. Adverse Drug Events (%) Reported with the Beta-Adrenergic Blocking Agents<sup>1-22</sup>**

Adverse Events	Single Entity Agents (A-N)								
	Acebutolol	Atenolol	Betaxolol	Bisoprolol	Carvedilol	Labetalol	Metoprolol	Nadolol	Nebivolol

**Table 10. Boxed Warning for Atenolol<sup>1</sup>**

<b>WARNING</b>
Advise patients with coronary artery disease who are being treated with atenolol against abrupt discontinuation of therapy. Severe exacerbation of angina and the occurrence of myocardial infarction and ventricular arrhythmias have been reported in patients with angina following the abrupt discontinuation of therapy with $\beta$ -blockers. The last two complications may occur with or without preceding exacerbation of the angina pectoris. As with other $\beta$ -blockers, when discontinuation of atenolol is planned, observe the patient carefully and advise the patient to limit physical activity to a minimum. If the angina worsens or acute coronary insufficiency develops, it is recommended that atenolol be promptly reinstated, at least temporarily. Because coronary artery disease is common and may be unrecognized, it may be prudent not to discontinue atenolol therapy abruptly, even in patients treated only for hypertension.

**Table 11. Boxed Warning for Metoprolol<sup>1</sup>**

<b>WARNING</b>
Ischemic heart disease: Following abrupt cessation of therapy with certain $\beta$ -blocking agents, exacerbations of angina pectoris and, in some cases, myocardial infarction have occurred. When discontinuing chronically administered metoprolol, particularly in patients with ischemic heart disease, gradually reduce the dosage over a period of one to two weeks and carefully monitor the patient. If angina markedly worsens or acute coronary insufficiency develops, reinstate metoprolol administration promptly, at least temporarily, and take other measures appropriate for the management of unstable angina. Warn patients against interruption or discontinuation of therapy without their health care provider's advice. Because coronary artery disease is common and may be unrecognized, it may be prudent not to discontinue metoprolol tartrate therapy abruptly, even in patients treated only for hypertension.

**Table 12. Boxed Warning for Nadolol<sup>1</sup>**

<b>WARNING</b>
Exacerbation of ischemic heart disease following abrupt withdrawal: Hypersensitivity to catecholamines has been observed in patients withdrawn from $\beta$ -blocker therapy; exacerbation of angina and, in some cases, myocardial infarction have occurred after abrupt discontinuation of such therapy. When discontinuing chronically administered nadolol, particularly in patients with ischemic heart disease, gradually reduce the dosage over a period of one to two weeks and carefully monitor the patient. If angina markedly worsens or acute coronary insufficiency develops, reinstitute nadolol administration promptly, at least temporarily, and take other measures appropriate for the management of unstable angina. Warn patients against interruption or discontinuation of therapy without the physician's advice. Because coronary artery disease is common and may be unrecognized, it may be prudent not to discontinue nadolol therapy abruptly, even in patients treated only for hypertension.

**Table 13. Boxed Warning for Propranolol<sup>1</sup>**

<b>WARNING</b>
Angina pectoris: There have been reports of exacerbation of angina and, in some cases, myocardial infarction, following abrupt discontinuance of propranolol therapy. Therefore, when discontinuance of propranolol is planned, the dosage should be gradually reduced over at least a few weeks, and the patient should be cautioned against interruption or cessation of therapy without a health care provider's advice. If propranolol therapy is interrupted and exacerbation of angina occurs, it is usually advisable to reinstitute propranolol therapy and take other measures appropriate for the management of angina pectoris. Because coronary artery disease may be unrecognized, it may be prudent to follow the above advice in patients considered at risk of having occult atherosclerotic heart disease who are given propranolol for other indications.

**Table 14. Boxed Warning for Sotalol<sup>1</sup>**

<b>WARNING</b>
To minimize the risk of induced arrhythmia, place patients initiated or reinitiated on sotalol AF or sotalol for a minimum of three days (on their maintenance dose) in a facility that can provide cardiac resuscitation, continuous electrocardiographic monitoring, and calculations of creatinine clearance. Calculate creatinine clearance prior to dosing. Do not substitute sotalol for sotalol AF because of significant differences in labeling (i.e., patient package insert, dosing administration, safety information).

**Table 15. Boxed Warning for Timolol<sup>1</sup>**

<b>WARNING</b>
Exacerbation of ischemic heart disease following abrupt withdrawal: Hypersensitivity to catecholamines has been observed in patients withdrawn from $\beta$ -blocker therapy; exacerbation of angina and, in some cases, myocardial infarction have occurred after abrupt discontinuation of such therapy. When discontinuing chronically administered timolol, particularly in patients with ischemic heart disease, gradually reduce the dosage over a period of one to two weeks and carefully monitor the patient. If angina markedly worsens or acute coronary insufficiency develops, reinstitute timolol administration promptly, at least temporarily, and take other measures appropriate for the management of unstable angina. Warn patients against interruption of discontinuation of therapy without the physician's advice. Because coronary artery disease is common and may be unrecognized, it may be prudent not to discontinue timolol therapy abruptly, even in patients treated only for hypertension.

## VII. Dosing and Administration

The usual dosing regimens for the  $\beta$ -adrenergic blocking agents are listed in Table 16.

**Table 16. Usual Dosing Regimens for the Beta-Adrenergic Blocking Agents<sup>3-22</sup>**

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
<b>Single Entity Agents</b>			
Acebutolol	<p><u>Hypertension:</u> Capsule: initial, 400 mg/day, twice daily dosing may be required for adequate control; maintenance, 200 to 1,200 mg/day in two divided doses; maximum, 1,200 mg/day</p> <p><u>Ventricular arrhythmias:</u> Capsule: initial: 200 mg twice daily; maintenance, gradual increase until optimal response, usually 600 to 1,200 mg/day; maximum, 1,200 mg/day</p>	Safety and efficacy in children have not been established.	Capsule: 200 mg 400 mg
Atenolol	<p><u>Angina pectoris:</u> Tablet: initial, 50 mg once daily; maintenance, if optimal response not achieved after one week, increase to 100 mg daily; maximum, 200 mg/daily</p> <p><u>Hypertension:</u> Tablet: initial: 50 mg once daily; maintenance, if optimal response not achieved, increase dose to 100 mg once daily; maximum, 100 mg/day</p> <p><u>Myocardial infarction:</u></p>	Safety and efficacy in children have not been established.	Tablet: 25 mg 50 mg 100 mg

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
	Tablet: 50 mg twice daily, or 100 mg once daily for 6 to 9 days or until hospital discharge		
Betaxolol	<u>Hypertension:</u> Tablet: initial, 10 mg once daily; maintenance, if optimal response not seen after seven to 14 days, may increase the dose to 20 mg/day; maximum, 40 mg/day	Safety and efficacy in children have not been established.	Tablet: 10 mg 20 mg
Bisoprolol	<u>Hypertension:</u> Tablet: initial, 2.5 to 5 mg once daily; maintenance, if optimal control is not achieved, dose may be increased to 10 mg daily and again to 20 mg/day if needed; maximum, 20 mg/day	Safety and efficacy in children have not been established.	Tablet: 5 mg 10 mg
Carvedilol	<p><u>Heart failure:</u> Extended-release capsule: initial, 10 mg once daily; maintenance, if tolerated, double the dose at intervals of &gt;14 days as needed; maximum, 80 mg once daily</p> <p>Tablet: initial, 3.125 mg twice daily; maintenance, if tolerated, double the dose at intervals of &gt;14 days as needed up to 50 mg twice daily; maximum, 25 mg twice daily (patients ≤85 kg) or 50 mg twice daily (patients &gt;85 kg)</p> <p><u>Hypertension:</u> Extended-release capsule: initial, 20 mg once daily; maintenance, if tolerated, double the dose every seven to 14 days as needed; maximum, 80 mg once daily</p> <p>Tablet: initial, 6.25 mg twice daily; maintenance, if tolerated, double the dose every seven to 14 days as needed; maximum, 25 mg twice daily</p> <p><u>Myocardial Infarction:</u> Capsule ER: initial, 10 to 20 mg once daily; maintenance: if tolerated, double the dose every 3 to 10 days as needed up to a maximum of 80 mg once daily</p> <p>Tablet IR: initial, 6.25 mg twice daily; maintenance: if tolerated, double the dose every 3 to 10 days as needed up to a maximum of 25 mg twice daily</p>	Safety and efficacy in children have not been established.	<p>Extended-release capsule: 10 mg 20 mg 40 mg 80 mg</p> <p>Tablet: 3.125 mg 6.25 mg 12.5 mg 25 mg</p>
Labetalol	<u>Hypertension:</u> Injection, tablet: initial: 100 mg twice daily; maintenance, titrate by increments of 100 mg twice daily every two to three days, usual dose is 200 to 400 mg twice daily; larger doses may be administered three times daily to improve tolerability;	Safety and efficacy in children have not been established.	<p>Injection: 5 mg/mL</p> <p>Tablet: 100 mg 200 mg 300 mg</p>

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
	maximum, doses of 1,200 to 2,400 mg/day have been used		
Metoprolol	<p><u>Angina pectoris:</u> Extended-release capsule, tablet: initial, 100 mg once daily; maintenance, gradually increase dose in weekly intervals; maximum, 400 mg/day</p> <p>Injection, tablet: initial, 100 mg/day in two divided doses; maintenance, gradually increase dose in weekly intervals, usual dose is 100 to 400 mg/day; maximum, 400 mg/day</p> <p><u>Heart failure:</u> Extended-release capsule, tablet: initial, 25 mg/day; maintenance, double the dose every two weeks up to 200 mg/day or highest dose tolerated</p> <p><u>Hypertension:</u> Extended-release capsule, tablet: initial, 25 to 100 mg once daily; maintenance, gradually increase dose in weekly intervals up to 400 mg/day</p> <p>Injection, tablet: initial, 50 to 100 mg/day in single or divided doses; maintenance, gradually increase dose in weekly intervals, usual dose is 100 to 450 mg/day; maximum, 450 mg/day</p> <p><u>Myocardial infarction:</u> Injection, tablet: initial, 100 mg twice daily; maintenance, 100 mg twice daily for at least three months</p>	<p><u>Hypertension in children <math>\geq 6</math> years of age:</u> Extended-release capsule, tablet: initial: 1 mg/kg once daily (maximum: 50 mg once daily); maintenance, adjust dose to optimal response up to 2 mg/kg or 200 mg/day; maximum, 2 mg/kg/day or 200 mg/day</p> <p>Safety and efficacy in children &lt;6 years of age have not been established.</p>	<p>Extended-release capsule (succinate): 25 mg 50 mg 100 mg 200 mg</p> <p>Extended-release tablet (succinate): 25 mg 50 mg 100 mg 200 mg</p> <p>Injection (tartrate): 5 mg/5 mL</p> <p>Tablet (tartrate): 25 mg 37.5 mg 50 mg 75 mg 100 mg</p>
Nadolol	<p><u>Angina pectoris:</u> Tablet: initial, 40 mg once daily; maintenance, increase dose by 40 to 80 mg every three to seven days until optimal response; maximum, 240 mg/day</p> <p><u>Hypertension:</u> Tablet: initial, 40 mg once daily; maintenance, increase dose gradually by 40 to 80 mg increments every seven to 21 days until optimal response; maximum, 320 mg/day</p>	Safety and efficacy in children have not been established.	Tablet: 20 mg 40 mg 80 mg
Nebivolol	<u>Hypertension:</u> Tablet: initial: 5 mg once daily; maintenance, increase in two week intervals until optimal response; maximum, 40 mg/day	Safety and efficacy in children have not been established.	Tablet: 2.5 mg 5 mg 10 mg 20 mg
Penbutolol	<u>Hypertension:</u> Tablet: initial, 20 mg once daily;	Safety and efficacy in children have not been	Tablet: 20 mg

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
	maintenance, 20 mg once daily, usual dose 10 to 40 mg once daily; maximum, 80 mg/day	established.	
Pindolol	<u>Hypertension:</u> Tablet: initial, 5 mg twice daily; maintenance, after three to four weeks, may be increase by 10 mg/day increments as needed; maximum, 60 mg/day	Safety and efficacy in children have not been established.	Tablet: 5 mg 10 mg
Propranolol	<p><u>Angina pectoris:</u> Extended-release capsule (Inderal LA<sup>®</sup>): initial, 80 mg once daily; maintenance, may gradually increase dose in three to seven day increments up to 160 mg once daily or higher, usual dose is 160 mg daily; maximum, 320 mg/day</p> <p>Solution, tablet: maintenance, 80 to 320 mg/day administered in two, three or four divided doses; maximum, 320 mg/day</p> <p><u>Cardiac arrhythmias:</u> Injection (ventricular arrhythmias): usual dose, 1 to 3 mg</p> <p>Solution, tablet (atrial fibrillation): maintenance, 10 to 30 mg in three to four divided doses before meals and at bedtime</p> <p><u>Essential tremor:</u> Solution, tablet: initial, 40 mg twice daily; maintenance, usual dose is 120 mg/day; maximum, 320 mg/day</p> <p><u>Hypertension:</u> Extended-release capsule (Inderal LA<sup>®</sup>): initial, 80 mg once daily; maintenance, may titrate dose up to 120 mg/day or higher, usual dose is 120 to 160 mg/day; maximum, 640 mg/day</p> <p>Extended-release capsule (InnoPran XL<sup>®</sup>): initial, 80 mg once daily at bedtime (around 10 pm); maintenance, may titrate dose up to 120 mg/day; maximum, 120 mg/day</p> <p>Solution, tablet: initial, 40 mg twice daily; maintenance, gradually increase the dose up to 640 mg/day divided into two to three doses, usual dose is 120 to 240 mg/day divided into two to three doses; maximum, 640 mg/day</p> <p><u>Hypertrophic subaortic stenosis:</u> Extended-release capsule (Inderal LA<sup>®</sup>):</p>	<p>Infantile hemangioma: Solution (Hemangeol<sup>®</sup>): Initiate treatment at 5 weeks to 5 months; initial, 0.15 mL/kg (0.6 mg/kg) twice daily at least 9 hours apart; after one week increase to 0.3 mL/kg (1.1 mg/kg) twice daily; after another week increase the dose to 0.4 mL/kg (1.7 mg/kg) twice daily and maintain for six months, readjusting for weight changes</p> <p>Safety and effectiveness for infantile hemangioma have not been established in pediatric patients greater than one year of age</p>	<p>Extended-release capsule: 60 mg 80 mg 120 mg 160 mg</p> <p>Injection: 1 mg/mL</p> <p>Solution: 4.28 mg/mL 20 mg/5 mL 40 mg/5 mL</p> <p>Tablet: 10 mg 20 mg 40 mg 60 mg 80 mg</p>

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
	<p>maintenance, 80 to 160 mg once daily</p> <p>Solution, tablet: 20 to 40 mg three to four times daily before meals and at bedtime</p> <p><u>Migraine:</u> Extended-release capsule (Inderal LA<sup>®</sup>): initial, 80 mg once daily; maintenance, may increase dose gradually up to 160 to 240 mg once daily, usual dose is 160 to 240 mg once daily; maximum, 240 mg/day</p> <p>Solution, tablet: initial, 80 mg daily in divided doses; maintenance, increase dose gradually up to 160 to 240 mg/day; maximum, 240 mg/day</p> <p><u>Myocardial Infarction:</u> Solution, tablet: initial, 40 mg three times daily; maintenance, after one month, titrate up to 60 to 80 mg three times daily as tolerated, usual dose is 180 to 240 mg in divided doses; maximum, 240 mg/day</p> <p><u>Pheochromocytoma:</u> Solution, tablet (operable tumors): 60 mg/day in divided doses for three days preoperatively as adjunct to <math>\alpha</math>-adrenergic blockade</p> <p>Solution, tablet (inoperable tumors): 30 mg/day in divided doses as adjunct to <math>\alpha</math>-adrenergic blockade</p>		
Sotalol	<p><u>Cardiac arrhythmias:</u> Solution, tablet (Betapace AF<sup>®</sup>, Sotylize<sup>®</sup>; maintenance of normal sinus rhythm): initial, 80 mg twice daily; maintenance, increase dose gradually with three days between increments up to 120 mg twice daily; maximum, 160 mg twice daily</p> <p>Solution, tablet (Betapace<sup>®</sup>, Sotylize<sup>®</sup>; ventricular arrhythmias): initial, 80 mg twice daily; maintenance, increase dose gradually with three days between increments up to 120 to 160 mg twice daily; maximum, 480 to 640 mg/day</p>	<p><u>Cardiac arrhythmias in children &gt;2 years of age:</u> Solution, tablet (Betapace AF<sup>®</sup>, Sotylize<sup>®</sup>; maintenance of normal sinus rhythm): initial, 30 mg/m<sup>2</sup> three times daily; maintenance, increase dose gradually with three days between increments up to 60 mg/m<sup>2</sup> three times daily; maximum, 60 mg/m<sup>2</sup> three times daily; neonate dosing available for Sotylize<sup>®</sup></p> <p>Solution, tablet (Betapace<sup>®</sup>, Sotylize<sup>®</sup>; ventricular Arrhythmias): initial,</p>	<p>Solution: 5 mg/mL</p> <p>Tablet: 80 mg, 120 mg, 160 mg, 240 mg</p>

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
		30 mg/m <sup>2</sup> three times daily; maintenance, increase dose gradually with three days between increments up to 60 mg/m <sup>2</sup> three times daily; maximum, 60 mg/m <sup>2</sup> three times daily; neonate dosing available for Sotylize®	
Timolol	<p><u>Hypertension:</u> Tablet: initial, 10 mg twice daily; maintenance, increase dose gradually in seven day increments up to 60 mg/day, usual dose is 20 to 40 mg/day; maximum, 60 mg/day divided into two doses</p> <p><u>Migraine:</u> Tablet: initial, 10 mg twice daily; maintenance, may increase dose up to 30 mg/day; maximum, 30 mg/day divided into two doses</p> <p><u>Myocardial infarction:</u> Tablet: 10 mg twice daily</p>	Safety and efficacy in children have not been established.	Tablet: 5 mg 10 mg 20 mg
<b>Combination Products</b>			
Atenolol and chlorthalidone	<p><u>Hypertension:</u> Tablet: initial: 50-25 mg once daily; maintenance, if optimum response is not achieved after one to two weeks, may increase to 100-25 mg once daily</p>	Safety and efficacy in children have not been established.	Tablet: 50-25 mg 100-25 mg
Bisoprolol and HCTZ	<p><u>Hypertension:</u> Tablet: initial, 2.5-6.25 mg once daily; maintenance, may titrate dose every seven to 14 days; maximum, 20-12.5 mg once daily</p>	Safety and efficacy in children have not been established.	Tablet: 2.5-6.25 mg 5-6.25 mg 10-6.25 mg
Metoprolol and HCTZ	<p><u>Hypertension:</u> Extended-release tablet: dosing must be individualized, the usual dose of metoprolol is 25 to 100 mg/day, and the usual dose of HCTZ is 12.5 to 50 mg/day</p> <p>Tablet: initial, 100-25 mg/day in single or divided doses; maintenance, may titrate dose gradually until desired effect is achieved, usual dose of metoprolol is 100 to 450 mg/day, and usual dose of HCTZ is 12.5 to 50 mg/day, may be administered in single or divided doses</p>	Safety and efficacy in children have not been established.	Tablet: 50-25 mg 100-25 mg 100-50 mg
Nadolol and bendroflumethiazide	<p><u>Hypertension:</u> Tablet: initial, 40-5 mg once daily; maintenance, if desired effect is not achieved, may increase dose to 80-5 mg once daily</p>	Safety and efficacy in children have not been established.	Tablet: 80-5 mg

HCTZ=hydrochlorothiazide, NYHA=New York Heart Association

## VIII. Effectiveness

Clinical studies evaluating the safety and efficacy of the  $\beta$ -adrenergic blocking agents are summarized in Table 17.

**Table 17. Comparative Clinical Trials with the Beta-Adrenergic Blocking Agents**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<b>Angina</b>				
<p>Pandhi et al.<sup>57</sup> (1985)</p> <p>Acebutolol 100 to 400 mg TID</p> <p>vs</p> <p>propranolol 40 to 160 mg TID</p> <p>vs</p> <p>placebo</p>	<p>DB, XO</p> <p>Patients with classical anginal symptoms of effort with <math>\geq 7</math> attacks per week and angina being stable for <math>\geq 8</math> to 12 weeks</p>	<p>N=24</p> <p>18 weeks</p>	<p>Primary: Incidence of anginal attack, number of nitroglycerin tablets used, exercise tolerance, side effects</p> <p>Secondary: Not reported</p>	<p>Primary: Both acebutolol and propranolol significantly reduced the incidence of anginal attacks per week compared to placebo (<math>P &lt; 0.001</math> for both groups), but the difference between the two groups was not significant (<math>P &gt; 0.05</math>).</p> <p>Both acebutolol and propranolol significantly reduced the number of nitroglycerin tablets used per week compared to placebo (<math>P &lt; 0.001</math> for both groups), but the difference between the two groups was not significant (<math>P &gt; 0.05</math>).</p> <p>Both acebutolol and propranolol significantly improved exercise tolerance compared to placebo (<math>P &lt; 0.001</math>), but the difference between the two groups was not significant (<math>P &gt; 0.05</math>).</p> <p>Side effects reported (i.e., insomnia, sweating, bitter taste, heart burn, muscle weakness) were similar between the two treatment groups. Clinical significance of the side effects was not reported.</p> <p>Secondary: Not reported</p>
<p>Jackson et al.<sup>58</sup> (1980)</p> <p>Atenolol 25, 50, 100, and 200 mg/day, each dose administered for a 2 week period</p> <p>vs</p>	<p>XO</p> <p>Adult patients with clinically stable exercise-induced angina for <math>\geq 3</math> months</p>	<p>N=10</p> <p>12 weeks</p>	<p>Primary: Anginal attack rate, nitroglycerin consumption, exercise data</p> <p>Secondary: Not reported</p>	<p>Primary: Compared to placebo, atenolol reduced the angina attack rate during all periods (<math>P &lt; 0.001</math>). A dose response was present with a decreasing number of attacks with increasing dosage. Doses of 100 and 200 mg were significantly more effective to 25 mg (<math>P &lt; 0.001</math> for both), but there was no significant difference between the 50 and 100 mg, or 100 and 200 mg (<math>P</math> values not reported).</p> <p>Nitroglycerin consumption declined in a parallel, dose-related fashion. Compared to placebo, all doses of atenolol decreased nitroglycerin consumption significantly (<math>P &lt; 0.001</math>), with no significant difference</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>placebo</p> <p>All patients received SB placebo for the first 4 weeks of the trial.</p>				<p>between 50 vs 100 and 200 mg, or 100 vs 200 mg (P values not reported).</p> <p>All doses of atenolol significantly reduced resting and exercise heart rate at three hours (P&lt;0.001) and 24 hours (P&lt;0.001) after ingestion. Atenolol was significantly more effective at 100 and 200 mg, with no significant difference between the two doses (P value not reported). The maximal exercise double product (heart rate times SBP) at the occurrence of chest pain was significantly reduced at peak and trough testing with all atenolol doses (P&lt;0.001 for all), but 100 and 200 mg were significantly more effective than 25 and 50 mg (P&lt;0.001 for both). The amount of exercise necessary to produce angina three hours after drug ingestion was increased by all atenolol doses; however, only 50 (P&lt;0.001), 100 (P&lt;0.005) and 200 mg (P&lt;0.001) showed significant improvement compared to placebo.</p> <p>Secondary: Not reported</p>
<p>Oh et al.<sup>59</sup> (2016)</p> <p>Atenolol 25 mg BID</p> <p>vs</p> <p>carvedilol 12.5 mg BID</p> <p>After a week of treatment, the initial dose of the study medication could be doubled</p>	<p>OL, PG, PRO, RCT</p> <p>Patients 20 to 80 years of age with stable angina pectoris who had a positive exercise treadmill test according to American College of Cardiology Foundation and American Heart Association guidelines</p>	<p>N=89</p> <p>6 months</p>	<p>Primary: BP, heart rate, treadmill exercise test, Seattle Angina Questionnaire, metabolic parameters</p> <p>Secondary: Not reported</p>	<p>Primary: Office SBP and DBP at baseline was similar between the two groups and had not changed at the end of the study. Both carvedilol and atenolol significantly reduced heart rate from baseline (76 ± 11 to 66 ± 9 beat/min, P&lt;0.001; 74 ± 9 to 64 ± 9 beat/min, P&lt;0.001, respectively). Improvement of time to ST-segment depression during the treadmill exercise and the Seattle Angina Questionnaire scores for angina stability and frequency after six months of treatment were similar between groups. There was no significant change from baseline in the level of fasting glucose, insulin, or glycated hemoglobin in either group. However, TC and LDL-C levels significantly reduced to a greater extent with carvedilol than with atenolol (-23 vs -10 and -38 vs -24%, respectively, P&lt;0.05 for both), although the rate of statin use was comparable. No changes were seen in HDL cholesterol and triglyceride levels after six months of treatment in both groups compared with baseline.</p> <p>Secondary: Not reported</p>
<p>Kardas et al.<sup>60</sup> (2007)</p>	<p>OL, PG, RCT</p> <p>Patients 40 to 75</p>	<p>N=112</p> <p>8 weeks</p>	<p>Primary: Overall compliance</p>	<p>Primary: The overall compliance significantly higher in the betaxolol group compared to the metoprolol group (86.5±21.3 vs 76.1±26.3%,</p>

				robust than the nonselective agents (P=0.049).  Secondary: Not reported
Brophy et al. <sup>92</sup> (2001)  β-blockers (bisoprolol, bucindolol, carvedilol, metoprolol and nebivolol)  vs  placebo	MA (22 trials)  Patients with CHF of various etiologies	N=10,135  3 to 23 months	Primary: Overall mortality, hospitalizations for CHF  Secondary: Not reported	Primary: β-blockers significantly reduced mortality compared to placebo (444 vs 624; OR, 0.65; 95% CI, 0.53 to 0.80).  β-blockers significantly reduced hospitalizations due to CHF compared to placebo (540 vs 754; RR, 0.64; 95% CI, 0.53 to 0.79).  The probability that β-blocker therapy reduced total mortality and hospitalizations for congestive heart failure was almost 100%. The best estimates of these advantages are 3.8 lives saved and four fewer hospitalizations per 100 patients treated in the first year after therapy. The probability that these benefits are clinically significant (>2 lives saved or >2 fewer hospitalizations per 100 patients treated) is 99%.
Whorlow et al. <sup>93</sup> (2000)  β-blockers (bisoprolol, bucindolol, carvedilol metoprolol, nebivolol)  vs  placebo	MA (18 trials)  Patients with NYHA class IV heart failure currently taking background therapy (ACE inhibitors and diuretics with or without digoxin)	N=8,119  3 to 21 months	Primary: Mortality in NYHA class IV patients  Secondary: Not reported	Primary: β-blockers demonstrated a 29% reduction in mortality compared to placebo in patients with NYHA class IV (RR, 0.71; 95% CI, 0.52 to 0.96).  The 29% risk reduction is similar to risk reduction seen with β-adrenergic blockers in other NYHA classes.  β-blockers demonstrated a 32% reduction in mortality compared to placebo in patients with NYHA class I to IV (HR, 0.68; 95% CI, 0.61 to 0.77).  Secondary: Not reported
Bouzamondo et al. <sup>94</sup> (2003)  β-blockers (bisoprolol, bucindolol,	MA  Randomized controlled evaluating patients with heart failure depending on	N=not specified  Duration varied	Primary: Overall mortality, hospitalized for worsening heart failure  Secondary:	Primary: β-blockers reduced overall mortality by 22% compared to placebo (95% CI, 16% to 28%).  β-blockers reduced hospitalizations due to worsening heart failure by 24% compared to placebo (95% CI, 20% to 29%).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
carvedilol, and metoprolol)  vs  placebo	NYHA class		Not reported	Benefits were similar for bisoprolol, metoprolol, and carvedilol regardless of NYHA class.  Secondary: Not reported
Jabbour et al. <sup>95</sup> (2010)  β-blockers (bisoprolol, carvedilol, metoprolol)	OL, XO  Patients with NYHA class I to III heart failure with a subgroup of patients with coexisting COPD	N=51  16 weeks	Primary: Post-bronchodilator FEV <sub>1</sub>  Secondary: Not reported	Primary: FEV <sub>1</sub> was significantly higher in patients receiving bisoprolol vs carvedilol, both in those with coexisting COPD (P<0.01) and without (P=0.02).  There was a significant difference between all patients receiving carvedilol versus those receiving metoprolol (P=0.04), however, when compared for coexisting COPD, there was no difference in FEV <sub>1</sub> .  There was no significant difference for all patients, those with COPD, or those with CHF only when metoprolol and bisoprolol were compared.
MERIT-HF Study Group <sup>96</sup> (1999) MERIT-HF  Metoprolol CR/XL 12.5 mg up to 200 mg QD  vs  placebo	DB, MC, PC, RCT  Symptomatic patients 40 to 80 years in NYHA class II to IV, with LVEF of 40% or less stabilized on standard therapy (diuretic and vasodilator)	N=3,991  1 year	Primary: All-cause mortality, all-cause mortality in combination with all-cause admission to hospital (time to first event)  Secondary: Not reported	Primary: Study was stopped early on the recommendation of the independent safety committee. All-cause mortality was significantly lower in the metoprolol CR/XL group than in the placebo group (145 [7.2%] vs 217 [11.0 %] deaths, RR, 0.66; 95% CI, 0.53 to 0.81; P=0.00009).  There were significantly fewer sudden deaths in the metoprolol CR/XL group than in the placebo group (79 vs 132; RR, 0.59; 95% CI, 0.45 to 0.78; P=0.0002) and deaths from worsening heart failure (30 vs 58; RR, 0.51; 95% CI, 0.33 to 0.79; P=0.0023).  Study drug was permanently stopped early in 13.9% of the patients in the metoprolol CR/XL group and in 15.3% of patients in the placebo group (RR, 0.90; 95% CI, 0.77 to 1.06).  Secondary: Not reported
Goldstein et al. <sup>97</sup> (2001) MERIT-HF	Sub group analysis of MERIT-HF	N=795  1 year	Primary: All-cause mortality,	Primary: There were 45 deaths (11.7% per patient year of follow-up) with metoprolol and 72 deaths (19.1%) with placebo. Metoprolol decreased

There was a reduction in systolic and diastolic load also (P&lt;0.01).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs placebo				The combination was well tolerated. The scores from the overall QOL questionnaire indicated an improvement with the combination (P=0.02).
Benetos et al. <sup>120</sup> (2000)  Bisoprolol and HCTZ 2.5-6.25 mg QD (fixed-dose combination product)  vs  amlodipine 5 mg QD	DB, MC, PG, RCT  Patients over 60 years with supine SBP 160 to 210 mm Hg and DBP <90 mm Hg	N=164  12 weeks	Primary: Changes in blood pressure, heart rate, adverse events, QOL scores  Secondary: Not reported	Primary: Both bisoprolol and HCTZ and amlodipine significantly reduced SBP (-20.0±13.7 and -19.6±14.2 mm Hg, respectively; P<0.001) and DBP (-4.5±7.4 and -2.4±8.4 mm Hg, respectively from baseline to week 12, but there was not a significant difference between the agents (SBP; P=0.85 and DBP; P=0.09).  Bisoprolol and HCTZ significantly reduced heart rate from baseline, but amlodipine did not (-7.6±8.4 [P<0.001] and -0.2±11.4 bpm, respectively).  Bisoprolol and HCTZ significantly reduced heart rate when compared to amlodipine (P=0.0001).  Overall adverse events were not significantly different between the amlodipine and the bisoprolol and HCTZ group (39 and 40%, respectively). Adverse events reported included headache, leg edema, fatigue and bradycardia but severity of events was not reported.  Overall QOL scores were not significantly different between the amlodipine and the bisoprolol and HCTZ group.  Secondary: Not reported
Prisant et al. <sup>121</sup> (1995)  Bisoprolol and HCTZ 2.5-6.25, 5-6.25, or 10-6.25 mg/day (fixed-dose combination product)  vs	DB, MC, PG, RCT  Patients ≥21 years with mild to moderate essential HTN, (average sitting DBP 95 to 114 mm Hg) each treatment was once daily and titrated to effect	N=218  17 weeks	Primary: Mean change from baseline in SBP and DBP, lab measurements, adverse events, QOL questionnaire  Secondary: Not reported	Primary: Mean decreases in SBP and DBP from baseline were 13.4/10.7 mm Hg for bisoprolol and HCTZ patients, 12.8/10.2 mm Hg for amlodipine patients, and 7.3/6.6 mm Hg for enalapril patients. The hypotensive effects were significant for all three groups (P<0.001).  SBP and DBP mean changes from baseline for the bisoprolol and HCTZ group and the amlodipine group were greater than the change from baseline for the enalapril group (P<0.01).  Response rates (DBP ≤90 mm Hg or ≥10 mm Hg decrease from baseline)

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>enalapril 5, 10, or 20 mg</p> <p>vs</p> <p>amlodipine 2.5, 5, or 10 mg</p>				<p>were 71% for the bisoprolol and HCTZ group, 69% for the amlodipine group, and 45% for the enalapril group. The response rates for the bisoprolol and HCTZ and the amlodipine groups differed significantly from the enalapril group (P&lt;0.01).</p> <p>Twenty nine percent of bisoprolol patients had adverse experiences compared to 42% of amlodipine patients (P=0.12). Nearly 47% of enalapril patients had adverse experience compared to bisoprolol (P=0.04). Adverse events reported included headache, fatigue, peripheral edema, and dizziness.</p> <p>Drug related adverse events were 16% for the bisoprolol and HCTZ patients, 21% for the amlodipine patients, and 23% for the enalapril patients. There was no significant difference between the groups.</p> <p>Enalapril demonstrated a mean decrease from baseline of 7.9 mg/dL for TC (P=0.02 vs amlodipine) and 6.6 mg/dL for LDL-C (P=0.04 vs amlodipine) which were not significantly different from the increase from the bisoprolol and HCTZ group of 1.7 mg/dL (P=0.07 vs enalapril) for TC and +0.6 mg/dL in LDL-C. However, the increase in TGs was highest for bisoprolol and HCTZ-treated patients compared to amlodipine- and enalapril-treated patients (P=0.08, for bisoprolol and HCTZ vs enalapril).</p> <p>There was not a significant difference from baseline or between treatment groups in QOL scores: 0.9 for the bisoprolol and HCTZ group, 0.5 for the amlodipine group, and 2.3 for the enalapril group.</p>
<p>Frishman et al.<sup>122</sup> (1994)</p> <p>Bisoprolol 2, 5, 10, or 40 mg QD</p> <p>vs</p> <p>HCTZ 6.25 or 25 mg QD</p>	<p>DB, MC, PC, RCT</p> <p>Patients 21 years and older with mild to moderate essential HTN whose weight was 35% of the ideal for height and frame and mean sitting DBP was stable and</p>	<p>N=512</p> <p>12 weeks</p>	<p>Primary: Changes in DBP and SBP</p> <p>Secondary: Not reported</p>	<p>Primary: All treatment groups (all doses) of bisoprolol, HCTZ and the combination of bisoprolol and HCTZ significantly reduced sitting DBP from baseline (P&lt;0.01).</p> <p>The reduction in blood pressure was significantly greater as the doses of the bisoprolol, HCTZ and the combination of bisoprolol-HCTZ were increased (P&lt;0.05).</p> <p>The combination bisoprolol and HCTZ significantly reduced sitting DBP compared to the separate agents as monotherapy (P&lt;0.01).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs  bisoprolol plus HCTZ, all possible combinations	between 95 to 115 mm Hg			<p>With higher doses of HCTZ, there was a significantly higher incidence of hypokalemia, defined as potassium &lt;3.5 mmol/L (P&lt;0.01). Incidence of hyperuricemia also significantly increased with the increase in HCTZ dose (P&lt;0.01). Adverse events associated with hypokalemia and hyperuricemia were not reported.</p> <p>As the dose of bisoprolol was increased, the frequency and severity of adverse events reported significantly increased (P&lt;0.05). Adverse events reported included asthenia, diarrhea, dyspepsia and somnolence, but severity of effects was not reported.</p> <p>Secondary: Not reported</p>
Frishman et al. <sup>123</sup> (1995)  Bisoprolol 5 mg QD  vs  HCTZ 25 mg QD  vs  bisoprolol and HCTZ 5-6.25 mg QD (fixed-dose combination product)  vs  placebo	DB, MC, PC, PG, RCT  Patients ≥21 years with mild to moderate (stage II or II) systemic HTN whose body weight was not >10% below or 35% above the ideal weight for height and frame, and were off all antihypertensive medications before study entry and sitting DBP was 95 to 115 mm Hg on 3 consecutive weekly visits	N=547  10 weeks	Primary: Changes in blood pressure and adverse events  Secondary: Not reported	Primary: All active treatment groups significantly reduced sitting DBP and SBP from baseline compared to placebo (P<0.01).  Addition of HCTZ 6.25 mg contributed significantly to the blood pressure lowering effects of bisoprolol 5 mg.  The combination bisoprolol and HCTZ 5-6.25 mg produced a significantly greater reduction in mean sitting DBP from baseline (-12.6±0.5 mm Hg) compared to bisoprolol 5 mg alone (-10.5±0.5 mm Hg; P=0.02) and HCTZ 25 mg alone (-8.5±0.5 mm Hg; P<0.01). Bisoprolol 5 mg monotherapy was significantly better a reducing DBP compared to HCTZ 25 mg alone (P=0.03).  The combination bisoprolol and HCTZ 5-6.25 mg produced a significantly greater reduction in mean sitting SBP from baseline (-15.8 mm Hg) compared to bisoprolol 5 mg alone (-10 mm Hg; P<0.01) and HCTZ 25 mg alone (-15.8 mm Hg; P<0.01). There was not a significant difference in mean reduction between bisoprolol 5 mg alone and HCTZ 25 mg alone.  Bisoprolol and HCTZ 5-6.25 mg in combination had a 73% response rate compared to 61% for the bisoprolol group and 47% for the HCTZ group.

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>Bisoprolol and HCTZ 5-6.25 mg in combination was found to be significantly more effective compared to bisoprolol 5 mg or HCTZ 25 mg in all subgroups of patients regardless of age, race, gender, or smoking history (<math>P&gt;0.05</math> for all comparisons).</p> <p>Bisoprolol and HCTZ 5-6.25 mg in combination did not have an increase in frequency or severity of adverse events. The adverse events were comparable to that in the placebo group and frequency among groups was not significant. The most common adverse events reported were headache, dizziness, fatigue, and cough.</p> <p>Significantly greater number patients in the HCTZ 25 mg group (6.5%) experienced hypokalemia (potassium <math>&lt;3.4</math> mEq/L) compared to the bisoprolol 5 mg group (0.7%; <math>P&lt;0.01</math>), the bisoprolol and HCTZ combination group (0.7%; <math>P&lt;0.01</math>), and placebo (0%; <math>P&lt;0.01</math>).</p> <p>Hyperglycemia occurred in 7.4% of patients in the HCTZ 25 mg group, which was significantly higher than in the placebo group (5.2%; <math>P=0.03</math>). Also, the incidence of hyperuricemia (uric acid <math>&gt;7.5</math> mg/dL) was significantly higher in the HCTZ 25 mg group (24.4%) compared to placebo (2.7%; <math>P&lt;0.01</math>).</p> <p>Secondary: Not reported</p>
<p>Williams et al.<sup>124</sup> (2015) PATHWAY-2</p> <p>Twelve weeks of once daily treatment with each of spironolactone (25 to 50 mg), bisoprolol (5 to 10 mg), doxazosin modified release (4</p>	<p>DB, PC, XO</p> <p>Patients 18 to 79 years of age with seated clinic SBP <math>\geq 140</math> mmHg (or <math>\geq 135</math> mmHg for patients with diabetes) and home SBP (18 readings over four days) <math>\geq 130</math> mmHg, despite treatment for at least three</p>	<p>N=335</p> <p>12 months</p>	<p>Primary: Average home SBP, recorded in the morning and the evening in triplicate, on four consecutive days before study visits</p> <p>Secondary: Clinic SBP, BP control rates, adverse events</p>	<p>Primary: The average reduction in home SBP by spironolactone was significantly greater compared to placebo (<math>-8.70</math> mmHg; 95% CI, <math>-9.72</math> to <math>-7.69</math>; <math>P&lt;0.0001</math>), compared to the mean of the other two active treatments (doxazosin and bisoprolol; <math>-4.26</math>; 95% CI, <math>-5.13</math> to <math>-3.38</math>; <math>P&lt;0.0001</math>), and compared to the individual treatments; versus doxazosin (<math>-4.03</math>; 95% CI, <math>-5.04</math> to <math>-3.02</math>; <math>P&lt;0.0001</math>) and versus bisoprolol (<math>-4.48</math>; 95% CI, <math>-5.50</math> to <math>-3.46</math>; <math>P&lt;0.0001</math>).</p> <p>Secondary: The results for seated clinic SBP largely mirror those seen with home SBP except that there was a large placebo effect on clinic BP that was not seen with home BP measurement.</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs propranolol  vs other (not specified)				13.21 to 13.84), atenolol 13.41% (CI, 12.91 to 13.93), propranolol 15.91% (CI, 14.83 to 17.05), and other 15.17% (CI, 13.88 to 16.56). There were no differences between atenolol and metoprolol at the end of the two years, both of which were statistically better than propranolol.  Compared to metoprolol, patients discharged on propranolol had 15% increased mortality at one year and 18% increased mortality at two years, which were significantly higher than metoprolol.  Secondary: Not reported
Testa et al. <sup>150</sup> (2014)  Patients taking atenolol  vs  Patients not taking atenolol	Observational  Patients aged ≥65 years with isolated HTN	N=972  12 years	Primary: Mortality  Secondary: Not reported	Primary: Univariate analysis shows that elderly participants taking atenolol show greater mortality than those not taking atenolol (52.4 vs 66.7%; P=0.047).  Cox regression analysis on 12-year mortality showed that age, number of diseases, number of drugs, basic activity of daily living ≥1%, and social support score were predictive; whereas female sex and Mini-Mental State Examination score were protective of long-term mortality. Additionally, pulse arterial pressure (HR, 1.02; 95% CI, 1.01 to 1.03; P=0.035) and atenolol use (HR, 1.89; 95% CI, 1.03 to 4.25; P<0.05) were predictive of long-term mortality.  Secondary: Not reported
Black et al. <sup>151</sup> (2003) CONVINCE  Atenolol 50 mg QD  vs  verapamil ER 180 mg QD	AC, DB, MC, RCT  Patients 55 years of age and older with HTN and ≥1 risk factor for cardiovascular disease	N=16,476  3 years	Primary: Composite first occurrence of acute MI, stroke or cardiovascular disease-related death  Secondary: Cardiovascular endpoints expanded, all-	Primary: There was no significant difference between the verapamil treatment group and the atenolol or HCTZ treatment groups in the composite primary endpoint (HR, 1.02; 95% CI, 0.88 to 1.18; P=0.77).  Secondary: There was no significant difference between the verapamil treatment group and the atenolol or HCTZ treatment group in rates of cardiovascular-related hospitalization (P=0.31), death (all-cause mortality) (P=0.32) and cancer rates (P=0.46).  Patients treated with verapamil experienced a significantly higher rate of

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs HCTZ 12.5 mg QD			cause mortality, cancer, hospitalization for bleeding, incidence of primary endpoints between 6AM and noon, adverse events	death or bleeding unrelated to stroke (HR, 1.54; 95% CI, 1.15 to 2.04; P=0.003).  Primary endpoints did not differ significantly based on time of day (P=0.43).  Patients treated with verapamil were more likely to withdraw for adverse events or symptoms than those treated with atenolol or HCTZ (P=0.02).
Dahlöf et al. <sup>152</sup> (2002) LIFE Atenolol 50 to 100 mg QD vs losartan 50 to 100 mg QD  HCTZ 12.5 to 25 mg QD was added if needed for blood pressure control.	DB, DD, PG, RCT  Patients 55 to 80 years old with essential HTN (sitting SBP/DBP 160 to 200 to 95 to 115 mm Hg) and left ventricular hypertrophy	N=9,193  ≥4 years	Primary: Composite of cardiovascular death, MI and stroke  Secondary: All-cause mortality, hospitalization for angina or heart failure, revascularization procedures, resuscitated cardiac arrest, new-onset diabetes	Primary: SBP fell by 30.2 and 29.1 mm Hg in the losartan and atenolol groups, respectively (treatment difference, P=0.017) and DBP fell by 16.6 and 16.8 mm Hg, respectively (treatment difference, P=0.37). MAP was 102.2 and 102.4 mm Hg, respectively (P value not significant). Heart rate decreased more in patients assigned to atenolol than losartan (-7.7 vs -1.8 beats/minute, respectively; P<0.0001).  Compared to atenolol, the primary composite occurred in 13.0% fewer patients receiving losartan (RR, 0.87; 95% CI, 0.77 to 0.98; P=0.021).  While there was no difference in the incidence cardiovascular mortality (P=0.206) and MI (P=0.491), losartan treatment resulted in a 24.9% relative risk reduction in stroke compared to atenolol (P=0.001).  Secondary: A 25% lower incidence of new-onset diabetes was reported with losartan compared to atenolol (P=0.001). There was no significant difference among the other secondary end points between the two treatment groups.  Note: At end point or end of follow-up, 18 and 26% of patients on losartan were receiving HCTZ alone or with other drugs, respectively. In the atenolol group, 16 and 22% of patients were receiving HCTZ alone or with other drugs, respectively.
Julius et al. <sup>153</sup> (2004) LIFE Black Subset Atenolol 50 to 100	Post hoc analysis  Patients 55 to 80 years old with essential HTN	N=523  ≥4 years	Primary: Composite of cardiovascular death, MI and stroke	Primary: Compared to atenolol (11.2%), losartan in the United States African American population resulted in a greater incidence of the composite end point (17.4%; P=0.033).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
mg QD vs losartan 50 to 100 mg QD  HCTZ 12.5 to 25 mg QD was added if needed for blood pressure control.	(sitting SBP/DBP 160 to 200/95 to 115 mm Hg) and left ventricular hypertrophy		Secondary: Not reported	HRs favored atenolol across all parameters (P=0.246 for cardiovascular mortality, P=0.140 for MI, and P=0.030 for stroke).  In African American patients, blood pressure reduction was similar in both groups, and regression of electrocardiographic-left ventricular hypertrophy was greater with losartan.  Secondary: Not reported
Lindholm et al. <sup>154</sup> (2002) LIFE Diabetic Subset  Atenolol 50 to 100 mg QD vs losartan 50 to 100 mg QD  HCTZ 12.5 to 25 mg QD was added if needed for blood pressure control.	Post hoc analysis  Patients 55 to 80 years old with essential HTN (sitting SBP/DBP 160 to 200/95 to 115 mm Hg) and left ventricular hypertrophy	N=1,195  ≥4 years	Primary: Composite of cardiovascular death, MI and stroke  Secondary: All-cause mortality	Primary: Compared to atenolol, losartan resulted in a 24% decrease in the primary composite end point (P=0.031).  Losartan treatment resulted in a 37% risk reduction in cardiovascular deaths vs atenolol (P=0.028).  Losartan treatment resulted in a 39% risk reduction in all-cause mortality vs atenolol (P=0.002).  Mean blood pressure fell to 146/79 mm Hg in losartan patients and 148/79 mm Hg in atenolol patients.  Secondary: Mortality from all causes was 63 and 104 in the losartan and atenolol groups, respectively (RR, 0.61; P=0.002).
Kjeldsen et al. <sup>155</sup> (2002) LIFE Isolated Systolic Hypertension Subset  Atenolol 50 to 100 mg QD	Post hoc analysis  Patients 55 to 80 years old with isolated systolic HTN (SBP of 160 to 200 mm Hg and DBP <90 mm Hg) and left ventricular	N=1,326  ≥4 years	Primary: Composite of cardiovascular death, MI, or stroke  Secondary: All-cause mortality	Primary: Compared to atenolol, losartan resulted in a trend towards a 25% reduction in the primary end point (P=0.06).  Losartan treatment resulted in a 46% risk reduction in cardiovascular mortality (P=0.01) and 40% risk reduction in stroke compared to atenolol (P=0.02). There was no difference in the incidence of MI.  Blood pressure was reduced by 28/9 and 28/9 mm Hg in the losartan and

mg BID	and a confirmed diagnosis with significant increase in cardiac enzymes		Not reported	atenolol groups after adjustment for diuretic use (0.247 vs 0.299; RR, 0.83; 95% CI, 0.56 to 1.23; P=0.39).  Of the nonserious adverse events reported, a greater incidence of colds hand and feet were reported in the atenolol group (38 [33.3%]) compared to the carvedilol group (24 [20%]; P=0.025).  Secondary: Not reported
Pasternak et al. <sup>168</sup> (2014)  Carvedilol  vs  metoprolol succinate	RETRO  Danish patients aged 50 to 84 years with HF and LVEF ≤40% who received carvedilol or metoprolol succinate treatment	N=11,664  Up to 3 years (Median 2.4)	Primary: All-cause mortality  Secondary: Cardiovascular mortality	Primary: The cumulative incidence of all-cause mortality was 18.3 and 18.8% in the carvedilol and metoprolol groups, respectively. After adjustment for propensity score, the risk of mortality did not differ significantly between carvedilol and metoprolol users (aHR, 0.99; 95% CI, 0.88 to 1.11).  Secondary: The risk of cardiovascular mortality was not significantly different between carvedilol and metoprolol users (aHR, 1.05; 95% CI, 0.88 to 1.26).
Seo et al. <sup>169</sup> (2015)  Carvedilol  vs  β1-selective β blockers (bisoprolol, metoprolol, and nebivolol)	PRO, propensity-score matched cohort  Patients ≥18 years of age with acute MI undergoing percutaneous coronary intervention	N=7,863  mean follow-up of 243 ± 144 days	Primary: All-cause death or MI during follow-up  Secondary: All-cause death, cardiac death, and MI	Primary: Of the 7,863 patients examined, 6,231 (79.2%) were treated with carvedilol and 1,632 (20.7%) were treated with β1-selective β-blockers. During the follow-up period, the primary end point of all-cause death or MI occurred in 94 patients (1.5%) in the carvedilol group and 31 patients (1.9%) in the β1-selective β-blockers group. In the multivariate Cox regression model, no differences in the risk of all-cause death or MI were observed between the carvedilol and β1-selective β-blocker groups.  Secondary: The risks of all-cause death, cardiac death, and MI were also similar between the carvedilol and β1-selective β-blocker groups during the follow-up period.
Olsson et al. <sup>170</sup> (1992)  Metoprolol 100 mg BID	MA (5 trials)  Patients with a past history of MI	N=5,474  3 months to 3 years	Primary: All-cause mortality, sudden deaths	Primary: Metoprolol significantly reduced all-cause mortality compared to placebo (188 vs 223 deaths; P=0.036).  Metoprolol significantly reduced sudden deaths compared to placebo (62

vs placebo			Secondary: Not reported	vs 104 deaths; P=0.002).  Secondary: Not reported
Piccini et al. <sup>171</sup> (2014)  Amiodarone  vs  sotalol  vs  no antiarrhythmic drug (AAD)	RETRO  Patients with CAD and AF	N=2,838  Median follow-up 4.2 years	Primary: All-cause mortality  Secondary: Not reported	Primary: In unadjusted and adjusted settings, mortality rates were lower in patients treated with sotalol compared with amiodarone or no AAD. After adjustment for baseline characteristics only, the 1-year mortality rate was 10% in those treated with sotalol, 20% in those treated with amiodarone, and 14% in those treated with no AAD (no P-value reported).  Landmark analysis at 60 days and one year was also performed. After adjustment and weighting, sotalol was associated with improved survival from 0 to 60 days compared with amiodarone (HR, 0.14; 95% CI, 0.06 to 0.32) but not at later time points ( $\geq 60$ days or $\geq 1$ year). Similarly, compared with no AAD therapy, sotalol was not associated with improved survival beyond 60 days. Cumulative survival after one year in patients treated with sotalol vs no AAD was also not improved (P=0.64).  Secondary: Not reported
No authors listed <sup>172</sup> (abstract) (1983)  Timolol  vs  placebo	DB, MC, PC, RCT  Patients <75 years of age surviving an acute MI	N=1,884  12 to 33 months	Primary: All-cause mortality  Secondary: Not reported	Primary: Long term treatment with timolol improved prognosis. A significant difference in life table mortality of 39.3% between treatments was observed (13.3 vs 21.9%; P=0.0003). The difference was due to a lower rate of sudden cardiac death with timolol compared to placebo (7.7 vs 13.9%; P=0.0001).  Secondary: Not reported
Patel et al. <sup>173</sup> (2014)  $\beta$ -blocker therapy (carvedilol, metoprolol)	RETRO  Medicare patients in the OPTIMIZE-HF registry (having a primary discharge)	N=2,198 (1099 propensity-matched pairs)  Up to 6 years	Primary: composite endpoint of all-cause mortality or HF rehospitalization	Primary: Discharge prescriptions for $\beta$ -blockers to older HF with preserved ejection fraction patients who were not receiving these drugs prior to admission had no association with the primary composite endpoint during a median of 2.2 years of follow-up (HR, 1.03; 95% CI, 0.94 to 1.13; P=0.569). This association was homogeneous across various clinically relevant

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
succinate, and bisoprolol at their respective guideline-recommended target doses of 50, 200, and 10 mg/day)  vs  no $\beta$ -blocker therapy	diagnosis of HF), aged $\geq 65$ years with EF $\geq 40\%$ who were eligible for new discharge prescriptions of $\beta$ -blockers	(Median 2.2)	Secondary: All-cause mortality, HF rehospitalization, and all-cause rehospitalization	subgroups.  Secondary: HRs for all-cause mortality and HF rehospitalization associated with a prescription for initiation of $\beta$ -blocker therapy were 0.99 (95% CI, 0.90 to 1.10; P=0.897) and 1.17 (95% CI, 1.03 to 1.34; P=0.014), respectively. The latter association lost significance when higher EF cutoffs of $\geq 45\%$ , $\geq 50\%$ and $\geq 55\%$ were used.
Hansson et al. <sup>174</sup> (2000) NORDIL  Conventional therapy (diuretic, $\beta$ -blocker or both)  vs  diltiazem 180 to 360 mg QD	BE, MC, OL, PRO, RCT  Patients 50 to 74 years of age with DBP $\geq 100$ mm Hg and previously untreated	N=10,881  4.5 years	Primary: Combined fatal and nonfatal stroke, fatal and nonfatal MI, other cardiovascular death  Secondary: Fatal plus nonfatal stroke and fatal plus nonfatal MI	Primary: The primary endpoint occurred in 403 of the diltiazem patients and 400 of the diuretic/ $\beta$ -blocker patients (RR, 1.00; 95% CI, 0.87 to 1.15; P=0.97).  Secondary: Rates of secondary endpoints were similar between the groups. Fatal plus nonfatal stroke occurred in 159 of the diltiazem patients and 196 of the diuretic/ $\beta$ -blocker patients (P=0.04).  Fatal plus nonfatal MI occurred in 183 of the diltiazem patients and 157 of the diuretic/ $\beta$ -blocker patients (P=0.17).  Other endpoints were not statistically different between the groups including cardiovascular death (P=0.41), all cardiac events (P=0.57) and congestive heart failure (P=0.42).
Messerli et al. <sup>175</sup> (1998)  $\beta$ -blockers (atenolol, metoprolol or pindolol)  vs	MA  10 RCTs lasting $\geq 1$ year, which used as first line agents diuretics and/or $\beta$ -blockers and reported morbidity and	N=16,164  1 year	Primary: Cardiovascular morbidity and mortality, all-cause morbidity  Secondary: Not reported	Primary: Diuretic treatment significantly reduced the odds for cardiovascular mortality by 25% (OR, 0.75; 95% CI, 0.64 to 0.87), while $\beta$ -blockers did not reduce cardiovascular mortality (OR, 0.98; 95% CI, 0.78 to 1.23; P values not reported).  Diuretic treatment significantly reduced the odds for all-cause mortality by 14% (OR, 0.86; 95% CI, 0.77 to 0.96), while $\beta$ -blockers did not reduce all-cause mortality (OR, 1.05; 95% CI, 0.88 to 1.25; P values not

or placebo				
Freemantle et al. <sup>178</sup> (1999)  β-blockers (acebutolol, alprenolol, atenolol, betaxolol, carvedilol, labetalol, oxprenolol*, pindolol, practolol*, propranolol, sotalol, timolol and xamoterol*)  vs  control (agents were not specified)	MA (82 trials)  Patients with acute or past MI	N=54,234  6 to 48 months	Primary: All-cause mortality  Secondary: Nonfatal reinfarction and withdrawal from treatment	Primary: The pooled random effects in short term trials demonstrated a mortality rate of 10.5% (3,062 out of 29,260 patients) which is a 4% reduction compared to the controlled groups (OR, 0.96; 95% CI, 0.85 to 1.08).  The pooled random effects in long term trials demonstrated a mortality rate of 9.7% (2415 out of 24974 patients) which is 23% reduction when compared to the controlled groups (OR, 0.77; 95% CI, 0.69 to 0.85).  Individually, only four drugs achieved a statistically significant reduction in the death: propranolol (OR, 0.71; CI, 0.59 to 0.85]), timolol (OR, 0.59; CI, 0.46 to 0.77), metoprolol (OR, 0.80; CI, 0.66 to 0.96; and acebutolol (OR, 0.49; CI, 0.25 to 0.93).  Secondary: A reduction in nonfatal re-infarctions of 0.9 events in every 100 (0.3 to 1.6) annually is suggested by this analysis; therefore about 107 patients would require treatment for one year to avoid one nonfatal reinfarction.  Overall, 5,151 of 21,954 patients (23.5%) withdrew from treatment. with withdrawal occurring more often in the β-blocker groups. When comparing to placebo, the difference in annualized rate of withdrawal was 1.16 in 100 patients treated (1.16; 95% CI, 0.56 to 1.76).

Drug regimen abbreviations: BID=twice daily, CR=controlled-release, ER=extended-release, QD=once daily, SR=sustained-release, TID=three times daily, XL=extended-release

Study design abbreviations: AC=active comparator, BE=blinded endpoint, DB=double blind, DD=double dummy, MA=meta analysis, MC=multicenter, OL=open label, PC=placebo controlled, PG=parallel group, PRO=prospective, RCT=randomized controlled trial, RETRO=retrospective, SB=single blind, XO=cross over

Miscellaneous abbreviations: ACE inhibitor=angiotensin converting enzyme inhibitor, AF=atrial fibrillation, Aix=augmentation index, aPWV=aortic pulse wave velocity, ARB=angiotensin II receptor blocker, CABG=coronary artery bypass graft, CAD=coronary artery disease, CHD=coronary heart disease, CHF=congestive heart failure, CI=confidence interval, COPD=chronic obstructive pulmonary disease, DBP=diastolic blood pressure, ECG=electrocardiogram, ESRD=end stage renal disease, FEV<sub>1</sub>=forced expiratory volume in one second, GFR=glomerular filtration rate, HDL-C=high-density lipoprotein cholesterol, HR=hazard ratio, HTN=hypertension, LDL-C=low-density lipoprotein cholesterol, LVEF=left ventricular ejection fraction, MAP=mean arterial pressure, MI=myocardial infarction, NYHA=New York Heart Association, OR=odds ratio, PAD=peripheral arterial disease, pro-BNP= pro-B-type natriuretic peptide, PVD=peripheral vascular disease, QOL=quality of life, RMSSD=root mean square of successive RR intervals, RR=relative risk, SBP=systolic blood pressure, SDNN=standard deviation of the normal RR intervals, TC=total cholesterol, TG=triglyceride, TIA=transient ischemic attack, WHO=World Health Organization

**Additional Evidence**

Dose Simplification

Nissinen et al. evaluated newly diagnosed hypertensive patients who received atenolol 100 mg and chlorthalidone 25 mg given as single entity products or as a fixed-dose combination. Each of the active drug combinations significantly lowered standing, supine and postexercise blood pressure. There was no significant difference among the treatment regimens.<sup>114</sup>

Stable Therapy

A search of Medline and PubMed did not reveal data pertinent to this topic.

Impact on Physician Visits

A search of Medline and PubMed did not reveal data pertinent to this topic.

**IX. Cost**

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of '\$' signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 18. Relative Cost of the Beta-Adrenergic Blocking Agents**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost

\*Generic is available in at least one dosage form or strength.

†Product was discontinued by manufacturer, but remains active in pharmacy system. Pricing information not available.

HCTZ=hydrochlorothiazide, N/A=not available

## X. Conclusions

All of the beta-adrenergic blocking agents ( $\beta$ -blockers) are approved for the treatment of hypertension, with the exception of sotalol.<sup>1-22</sup> Some of the products are also approved for the treatment of angina, arrhythmias, essential tremor, heart failure, hypertension, hypertrophic aortic stenosis, infantile hemangiomas, migraine prophylaxis, myocardial infarction, and pheochromocytoma.<sup>1-22</sup> These agents differ with regards to their adrenergic-receptor blockade, membrane stabilizing and intrinsic sympathomimetic activities, as well as lipophilicity.<sup>1,2,25</sup> All of the agents are available in a generic formulation, with the exception of penbutolol.

Several national and international guidelines address the use of  $\beta$ -blockers.<sup>26-56</sup> Due to improvements in cardiovascular morbidity and mortality, treatment guidelines recommend the use of a  $\beta$ -blocker in patients with the following conditions: acute coronary syndromes, angina, arrhythmias, coronary artery disease, heart failure, left ventricular dysfunction, post-myocardial infarction, and infantile hemangiomas.<sup>26-56</sup> There are several published guidelines on the treatment of hypertension. Thiazide-type diuretics are frequently recommended as initial therapy in patients with uncomplicated hypertension.<sup>40-48</sup> According to the National Heart, Lung, and Blood Institute's Eighth Report of The Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 8), thiazide-type diuretics should be utilized first-line for most patients with hypertension, either alone or in combination with another hypertensive from a different medication class (e.g., ACE inhibitors, ARBs,  $\beta$ -blockers, calcium channel blockers).<sup>42</sup> Several guidelines consistently recommend that the selection of an antihypertensive agent be based on compelling indications for use.<sup>40-48</sup> Most patients will require more than one antihypertensive medication to achieve blood pressure goals.<sup>40-47</sup>  $\beta$ -blockers are recommended as one of several initial options for the prevention of migraine headaches (metoprolol and propranolol), as well as for the treatment of essential tremor (propranolol).<sup>50-52,54,55</sup> The Clinical Practice Guideline for the Management of Infantile Hemangiomas was published in January 2019 and recommends the use of oral propranolol as the first-line agent for the treatment.<sup>56</sup> The oral solution formulation of propranolol, under the brand name Hemangeol<sup>®</sup>, is the first agent to gain FDA-approval for this indication.<sup>12</sup>

Numerous clinical trials have shown that the  $\beta$ -blockers can effectively lower blood pressure when administered alone or in combination with other antihypertensive agents. Comparative studies have demonstrated similar efficacy among the  $\beta$ -blockers.<sup>102-148</sup> Most patients will require more than one antihypertensive agent to achieve blood pressure goals.<sup>40-47</sup> The use of a fixed-dose combination product may simplify the treatment regimen and improve adherence.<sup>43,44</sup> However, there are no prospective, randomized trials that have demonstrated better clinical outcomes with a fixed-dose combination product compared to the coadministration of the individual components as separate formulations.<sup>105</sup>

In patients with chronic stable angina,  $\beta$ -blockers improve exercise tolerance and reduce the frequency of attacks. Head-to-head trials have demonstrated similar efficacy among several of the  $\beta$ -blockers.<sup>57-65</sup> In patients with heart

failure,  $\beta$ -blockers (bisoprolol, carvedilol, and metoprolol succinate) have been shown to reduce mortality, sudden death, cardiovascular deaths, and death due to heart failure. Clinical trials supporting the use of carvedilol in patients with mild-to-severe heart failure were conducted with the immediate-release formulation.<sup>76-83,86,87,91-94,96-98</sup> Data to support the use of the extended-release capsules for the treatment of heart failure is based on pharmacokinetic and pharmacodynamic parameters that demonstrated bioequivalence with the immediate-release formulation.<sup>6</sup>

In general, adverse events are similar among the  $\beta$ -blockers. Common adverse effects include fatigue, cold hands, dizziness, and weakness.<sup>1-22</sup>  $\beta$ -blockers that are more selective for the  $\beta_1$ -receptors (atenolol and metoprolol) may be safer to use in those with reactive airway disease as they are less likely to cause bronchospasm.<sup>23,25</sup>

There is insufficient evidence to support that one brand beta-adrenergic blocking agent is safer or more efficacious than another. Formulations without a generic alternative should be managed through the medical justification portion of the prior authorization process.

Therefore, all brand beta-adrenergic blocking agents within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

## **XI. Recommendations**

No brand beta-adrenergic blocking agent is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Dihydropyridines  
AHFS Class 242808  
May 4, 2022**

**I. Overview**

The movement of calcium ions is essential for the function of all types of muscle, including cardiac and vascular smooth muscle. When this flow is reduced, the result is a weakening of muscle contraction and relaxation of muscle tissue.<sup>1-3</sup> Relaxation of coronary vascular smooth muscle increases the flow of oxygenated blood into the myocardium, while relaxation of arteriolar smooth muscle decreases peripheral vascular resistance.<sup>3-5</sup> Both coronary and systemic vasodilation serve to reduce cardiac workload. The calcium-channel blocking agents include dihydropyridines and nondihydropyridines. Although they have different binding sites on the L-type calcium channel, both block the transmembrane influx of calcium ions into cardiac and vascular smooth muscle. The nondihydropyridines also block the T-type calcium channel in the atrioventricular node.<sup>1-5</sup>

The dihydropyridines are approved for the treatment of angina and hypertension. Amlodipine is also indicated to reduce the risk of hospitalization due to angina and to reduce the risk of a coronary revascularization procedure in patients with recently documented coronary artery disease.<sup>1,2,6-17</sup> They are potent vasodilators and have little effect on cardiac muscle contractility or conduction. The dihydropyridines are available in a variety of single entity formulations. Amlodipine is also available in combination with benazepril, olmesartan, valsartan, or valsartan-hydrochlorothiazide. Angiotensin converting enzyme (ACE) inhibitors block the conversion of angiotensin I to angiotensin II, and also inhibit the breakdown of bradykinin, a potent vasodilator. Angiotensin II receptor antagonists block the angiotensin II receptor subtype AT<sub>1</sub>, preventing the negative effects of angiotensin II, regardless of its origin. Hydrochlorothiazide inhibits the reabsorption of sodium and chloride in the cortical thick ascending limb of the loop of Henle and the early distal tubules. This action leads to an increase in the urinary excretion of sodium and chloride.<sup>1,2</sup>

The dihydropyridines that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. All of the products with the exception of clevidipine is available in a generic formulation. This class was last reviewed in February 2020.

**Table 1. Dihydropyridines Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
<b>Single Entity Agents</b>			
Amlodipine	suspension, tablet	Katerzia <sup>®</sup> , Norvasc <sup>®*</sup>	amlodipine
Clevidipine	injection <sup>^</sup>	Cleviprex <sup>®</sup>	none
Felodipine	extended-release tablet	N/A	felodipine
Isradipine	capsule	N/A	isradipine
Nicardipine	capsule*, injection*	Cardene-NACL <sup>®^*</sup>	nicardipine
Nifedipine	capsule, extended-release tablet	Adalat CC <sup>®*</sup> , Procardia XL <sup>®*</sup>	nifedipine
Nimodipine	capsule*, solution	Nymalize <sup>®</sup>	nimodipine
Nisoldipine	extended-release tablet*	Sular ER <sup>®*</sup>	nisoldipine
<b>Combination Products</b>			
Amlodipine and benazepril	capsule	Lotrel <sup>®*</sup>	amlodipine and benazepril
Amlodipine and olmesartan	tablet	Azor <sup>®*</sup>	amlodipine and olmesartan
Amlodipine and valsartan	tablet	Exforge <sup>®*</sup>	amlodipine and valsartan
Amlodipine, valsartan, and hydrochlorothiazide	tablet	Exforge HCT <sup>®*</sup>	amlodipine, valsartan, and hydrochlorothiazide

\*Generic is available in at least one dosage form or strength.

<sup>^</sup>Product is primarily administered in an institution.

N/A=Not available

## II. Evidence-Based Medicine and Current Treatment Guidelines

Current treatment guidelines that incorporate the use of the dihydropyridines are summarized in Table 2.

**Table 2. Treatment Guidelines Using the Dihydropyridines**

Clinical Guideline	Recommendations
<p>American College of Cardiology/American Heart Association: <b>2007 Chronic Angina Focused Update of the 2002 Guidelines for the Management of Patients With Chronic Stable Angina (2007)</b><sup>18</sup></p>	<ul style="list-style-type: none"> <li>• Aspirin should be started at 75 to 162 mg/day and continued indefinitely in all patients, unless contraindicated.</li> <li>• Use of warfarin in conjunction with aspirin and/or clopidogrel is associated with an increased risk of bleeding and should be monitored closely.</li> <li>• Patients with hypertension and established coronary artery disease (CAD) should be treated with blood pressure medication(s) as tolerated, including angiotensin converting enzyme (ACE) inhibitors and/or <math>\beta</math>-adrenergic antagonists (<math>\beta</math>-blockers) with the addition of other medications as needed to achieve blood pressure goals of &lt;140/90 or &lt;130/80 mm Hg for patients with chronic kidney disease or diabetes.</li> <li>• Long-acting calcium channel blocking agents or long-acting nitrates may be used if <math>\beta</math>-blockers are contraindicated. Immediate-release and short-acting dihydropyridine calcium channel blockers can increase adverse cardiac events and should not be used.</li> <li>• Long-acting calcium channel blockers or long-acting nitrates may be used with <math>\beta</math>-blockers if initial treatment is not successful.</li> <li>• ACE inhibitors should be used indefinitely in patients with a left ventricular ejection fraction (LVEF) <math>\leq</math>40% and in those with hypertension, diabetes or chronic kidney disease, unless contraindicated.</li> <li>• ACE inhibitors should also be used indefinitely in patients at lower risk (mildly reduced or normal LVEF in whom cardiovascular risk factors remain well controlled and revascularization has been performed), unless contraindicated.</li> <li>• Angiotensin II receptor blockers (ARBs) are recommended in patients with hypertension, those who have an indication for an ACE inhibitor and are intolerant to them, who have heart failure, or who have had a myocardial infarction (MI) and have a LVEF <math>\leq</math>40%.</li> <li>• ARBs may be considered in combination with an ACE inhibitor for heart failure due to left ventricular systolic dysfunction.</li> <li>• Aldosterone blockade is recommended in patients post-MI without significant renal dysfunction or hyperkalemia who are already receiving therapeutic doses of an ACE inhibitor and a <math>\beta</math>-blocker, have a LVEF <math>\leq</math>40% and have either diabetes or heart failure.</li> <li>• It is beneficial to start and continue <math>\beta</math>-blocker therapy indefinitely in all patients who have had a MI, acute coronary syndrome or left ventricular dysfunction with or without heart failure symptoms, unless contraindicated.</li> <li>• Annual influenza vaccination is recommended in patients with cardiovascular disease.</li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Diagnosis and Management of Chronic Coronary Syndromes (2019)</b><sup>19</sup></p>	<p><u>Pharmacological management of stable coronary artery disease (CAD) patients</u></p> <ul style="list-style-type: none"> <li>• The two aims of the pharmacological management of stable CAD patients are to obtain relief of symptoms and to prevent CV events.</li> <li>• Optimal medical treatment indicates at least one drug for angina/ischaemia relief plus drugs for event prevention.</li> <li>• It is recommended to educate patients about the disease, risk factors and treatment strategy.</li> <li>• It is indicated to review the patient's response soon after starting therapy.</li> <li>• Concomitant use of a proton pump inhibitor is recommended in patients receiving aspirin monotherapy, DAPT, or DOAC monotherapy who are at high risk of gastrointestinal bleeding.</li> <li>• Lipid-lowering drugs: if goals are not met on maximum tolerated dose of a statin,</li> </ul>

Clinical Guideline	Recommendations
	<p>consideration of combination therapy with ezetimibe or a PCSK9 inhibitor is recommended</p> <ul style="list-style-type: none"> <li>• ACE inhibitors should be considered in patients at a very high risk of cardiovascular adverse events</li> <li>• Angina/ischemia relief: <ul style="list-style-type: none"> <li>○ Short-acting nitrates are recommended.</li> <li>○ First-line treatment is indicated with <math>\beta</math>-blockers and/or calcium channel blockers to control heart rate and symptoms.</li> <li>○ Long-acting nitrates should be considered as a second-line treatment option when initial therapy with a <math>\beta</math>-blocker and/or a non-DHP-calcium channel blocker is contraindicated, poorly tolerated, or inadequate in controlling angina symptoms</li> <li>○ Nicorandil, ranolazine, ivabradine, or trimetazidine should be considered as a second-line treatment to reduce angina frequency and improve exercise tolerance in subjects who cannot tolerate, have contraindications to, or whose symptoms are not adequately controlled by beta-blockers, CCBs, and long-acting nitrates.</li> <li>○ According to comorbidities/tolerance, it is indicated to use second-line therapies as first-line treatment in selected patients.</li> <li>○ In asymptomatic patients with large areas of ischaemia (&gt;10%) <math>\beta</math>-blockers should be considered.</li> <li>○ In patients with vasospastic angina, calcium channel blockers and nitrates should be considered and beta-blockers avoided.</li> </ul> </li> <li>• Event prevention: <ul style="list-style-type: none"> <li>○ Low-dose aspirin daily is recommended in all stable CAD patients.</li> <li>○ Clopidogrel is indicated as an alternative in case of aspirin intolerance.</li> <li>○ Statins are recommended in all stable CAD patients.</li> <li>○ It is recommended to use ACE inhibitors (or ARBs) if presence of other conditions (e.g., heart failure, hypertension or diabetes).</li> </ul> </li> </ul> <p><u>Treatment in patients with microvascular angina</u></p> <ul style="list-style-type: none"> <li>• It is recommended that all patients receive secondary prevention medications including aspirin and statins.</li> <li>• <math>\beta</math>-blockers are recommended as a first-line treatment.</li> <li>• Calcium antagonists are recommended if <math>\beta</math>-blockers do not achieve sufficient symptomatic benefit or are not tolerated.</li> <li>• ACE inhibitors or nicorandil may be considered in patients with refractory symptoms.</li> <li>• Xanthine derivatives or nonpharmacological treatments such as neurostimulatory techniques may be considered in patients with symptoms refractory to the above listed drugs.</li> </ul> <p><u>Stenting and peri-procedural antiplatelet strategies in stable CAD patients</u></p> <ul style="list-style-type: none"> <li>• Drug-eluting stent (DES) is recommended in stable CAD patients undergoing stenting if there is no contraindication to prolonged dual antiplatelet therapy (DAPT).</li> <li>• Aspirin is recommended for elective stenting.</li> <li>• Clopidogrel is recommended for elective stenting.</li> <li>• Prasugrel or ticagrelor should be considered in patients with stent thrombosis on clopidogrel without treatment interruption.</li> <li>• GP IIb/IIIa antagonists should be considered for bailout situation only.</li> <li>• Platelet function testing or genetic testing may be considered in specific or high risk situations (e.g., prior history of stent thrombosis; compliance issue; suspicion of resistance; high bleeding risk) if results may change the treatment strategy.</li> <li>• Prasugrel or ticagrelor may be considered in specific high-risk situations of</li> </ul>

Clinical Guideline	Recommendations
	<p>elective stenting (e.g., left main stenting, high risk of stent thrombosis, diabetes).</p> <ul style="list-style-type: none"> <li>• Pretreatment with clopidogrel (when coronary anatomy is not known) is not recommended.</li> <li>• Routine platelet function testing (clopidogrel and aspirin) to adjust antiplatelet therapy before or after elective stenting is not recommended.</li> <li>• Prasugrel or ticagrelor is not recommended in low-risk elective stenting.</li> <li>• After uncomplicated PCI, early cessation (<math>\leq 1</math> week) of aspirin, and continuation of dual therapy with oral anticoagulation therapy and clopidogrel should be considered if the risk of stent thrombosis is low</li> <li>• Triple therapy with aspirin, clopidogrel, and a DOAC for <math>\geq 1</math> month should be considered when the risk of stent thrombosis outweighs the bleeding risk, with a total of no more than six months</li> </ul> <p><u>Follow-up of revascularized stable coronary artery disease patients</u></p> <ul style="list-style-type: none"> <li>• It is recommended that all revascularized patients receive a secondary prevention and be scheduled for follow-up visit.</li> <li>• It is recommended to instruct patients before discharge about return to work and resumption of full activities. Patients have to be advised to seek immediate medical contact if symptoms (re-) occur.</li> <li>• Single antiplatelet therapy, usually aspirin, is recommended indefinitely.</li> <li>• DAPT is indicated after bare metal stent (BMS) for at least one month.</li> <li>• DAPT is indicated for six to 12 months after second generation DES.</li> <li>• DAPT may be used for more than one year in patients at high ischemic risk (e.g., stent thrombosis, recurrent acute coronary syndrome on DAPT, post MI/diffuse CAD) and low bleeding risk.</li> <li>• DAPT for one to three months may be used after DES implantation in patients at high bleeding risk or with undeferrable surgery or concomitant anticoagulant treatment.</li> </ul> <p><u>Antithrombotic therapy in patients with chronic coronary syndrome:</u></p> <ul style="list-style-type: none"> <li>• Addition of a second antithrombotic drug to aspirin for long-term secondary prevention should be considered in patients with at least a moderately increased risk of ischemic events and without high bleeding risk</li> <li>• When oral anticoagulation is initiated in patients with AF, a DOAC is recommended in preference to VKA therapy.</li> </ul>
<p>American College of Physicians/ American College of Cardiology Foundation/ American Heart Association/ American Association for Thoracic Surgery/ Preventive Cardiovascular Nurses Association/ Society of Thoracic Surgeons: <b>Management of Stable Ischemic Heart Disease (2012)</b><sup>20</sup></p>	<p><u>Medical therapy to prevent MI and death in patients with stable IHD</u></p> <ul style="list-style-type: none"> <li>• Aspirin 75 to 162 mg daily should be continued indefinitely in the absence of contraindications.</li> <li>• Treatment with clopidogrel is a reasonable option when aspirin is contraindicated.</li> <li>• Dipyridamole should not be used as antiplatelet therapy.</li> <li>• Beta-blocker therapy should be initiated and continued for three years in all patients with normal left ventricular (LV) function following MI or acute coronary syndromes.</li> <li>• Metoprolol succinate, carvedilol, or bisoprolol should be used for all patients with systolic LV dysfunction (ejection fraction <math>\leq 40\%</math>) with heart failure or prior MI, unless contraindicated.</li> <li>• ACE inhibitors should be prescribed in all patients with stable IHD who also have hypertension, diabetes, LV systolic dysfunction (ejection fraction <math>\leq 40\%</math>), and/or chronic kidney disease, unless contraindicated.</li> <li>• Angiotensin-receptor blockers (ARBs) are recommended for patients with stable IHD who have hypertension, diabetes, LV systolic dysfunction, or chronic kidney disease and have indications for, but are intolerant of, ACE inhibitors.</li> <li>• Patients should receive an annual influenza vaccine.</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Medical therapy for relief of symptoms in patients with stable IHD</u></p> <ul style="list-style-type: none"> <li>• Beta-blockers are recommended as initial therapy for relief of symptoms.</li> <li>• Calcium channel blockers or long-acting nitrates should be prescribed for relief of symptoms when <math>\beta</math>-blockers are contraindicated or cause unacceptable side effects.</li> <li>• Calcium channel blockers or long-acting nitrates, in combination with <math>\beta</math>-blockers, should be prescribed for relief of symptoms when initial treatment with <math>\beta</math>-blockers is unsuccessful.</li> <li>• Nitroglycerin or nitroglycerin spray should be used for immediate relief of angina.</li> <li>• Ranolazine is a fourth-line agent reserved for patients who have contraindications to, do not respond to, or cannot tolerate <math>\beta</math>-blockers, calcium-channel blockers, or long-acting nitrates.</li> </ul>
<p>American College of Cardiology Foundation/American Heart Association: <b>2014 American Heart Association/ American College of Cardiology Foundation Guideline for the Management of Patients With Non–ST-Elevation Acute Coronary Syndromes (2014)</b><sup>21</sup></p>	<p><u>Early hospital care- standard medical therapies</u></p> <ul style="list-style-type: none"> <li>• Supplemental oxygen should be administered to patients with non-ST-elevation acute coronary syndrome (NSTEMI-ACS) with arterial oxygen saturation &lt;90%, respiratory distress, or other high risk features of hypoxemia.</li> <li>• Anti-ischemic and analgesic medications <ul style="list-style-type: none"> <li>○ Nitrates <ul style="list-style-type: none"> <li>▪ Patients with NSTEMI-ACS with continuing ischemic pain should receive sublingual nitroglycerin (0.3 to 0.4 mg) every 5 minutes for up to three doses, after which an assessment should be made about the need for intravenous nitroglycerin.</li> <li>▪ Intravenous nitroglycerin is indicated for patients with NSTEMI-ACS for the treatment of persistent ischemia, heart failure, or hypertension.</li> <li>▪ Nitrates should not be administered to patients who recently received a phosphodiesterase inhibitor, especially within 24 hours of sildenafil or vardenafil, or within 48 hours of tadalafil.</li> </ul> </li> <li>○ Analgesic therapy <ul style="list-style-type: none"> <li>▪ In the absence of contraindications, it may be reasonable to administer morphine sulphate intravenously to patients with NSTEMI-ACS if there is continued ischemic chest pain despite treatment with maximally tolerated anti-ischemic medications.</li> <li>▪ Nonsteroidal anti-inflammatory drugs (NSAIDs) (except aspirin) should not be initiated and should be discontinued during hospitalization due to the increased risk of major adverse cardiac event associated with their use</li> </ul> </li> <li>○ Beta-adrenergic blockers <ul style="list-style-type: none"> <li>▪ Oral <math>\beta</math>-blocker therapy should be initiated within the first 24 hours in patients who do not have any of the following: 1) signs of HF, 2) evidence of low-output state, 3) increased risk for cardiogenic shock, or 4) other contraindications to <math>\beta</math>-blockade (e.g., PR interval &gt;0.24 second, second- or third-degree heart block without a cardiac pacemaker, active asthma, or reactive airway disease)</li> <li>▪ In patients with concomitant NSTEMI-ACS, stabilized heart failure, and reduced systolic function, it is recommended to continue <math>\beta</math>-blocker therapy with one of the three drugs proven to reduce mortality in patients with heart failure: sustained-release metoprolol succinate, carvedilol, or bisoprolol.</li> <li>▪ Patients with documented contraindications to <math>\beta</math>-blockers in the first 24 hours should be re-evaluated to determine subsequent eligibility.</li> </ul> </li> <li>○ Calcium channel blockers (CCBs) <ul style="list-style-type: none"> <li>▪ In patients with NSTEMI-ACS, continuing or frequently recurring ischemia, and a contraindication to <math>\beta</math>-blockers, a nondihydropyridine CCB (e.g., verapamil or diltiazem) should be given as initial therapy in the absence of clinically significant LV dysfunction, increased risk for cardiogenic shock, PR interval &gt;0.24 seconds, or second or third degree</li> </ul> </li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>atrioventricular block without a cardiac pacemaker.</p> <ul style="list-style-type: none"> <li>▪ Oral nondihydropyridine calcium antagonists are recommended in patients with NSTEMI-ACS who have recurrent ischemia in the absence of contraindications, after appropriate use of <math>\beta</math>-blockers and nitrates.</li> <li>▪ CCBs are recommended for ischemic symptoms when <math>\beta</math>-blockers are not successful, are contraindicated, or cause unacceptable side effects.</li> <li>▪ Long-acting CCBs and nitrates are recommended in patients with coronary artery spasm.</li> <li>▪ Immediate-release nifedipine should not be administered to patients with NSTEMI-ACS in the absence of <math>\beta</math>-blocker therapy.</li> </ul> <ul style="list-style-type: none"> <li>○ Other anti-ischemic interventions <ul style="list-style-type: none"> <li>▪ Ranolazine is currently indicated for treatment of chronic angina; however, it may also improve outcomes in NSTEMI-ACS patients due to a reduction in recurrent ischemia.</li> </ul> </li> <li>○ Cholesterol management <ul style="list-style-type: none"> <li>▪ High-intensity statin therapy should be initiated or continued in all patients with NSTEMI-ACS and no contraindications to its use. Treatment with statins reduces the rate of recurrent MI, coronary heart disease mortality, need for myocardial revascularization, and stroke.</li> <li>▪ It is reasonable to obtain a fasting lipid profile in patients with NSTEMI-ACS, preferably within 24 hours of presentation.</li> </ul> </li> </ul> <ul style="list-style-type: none"> <li>• Inhibitors of renin-angiotensin-aldosterone system <ul style="list-style-type: none"> <li>○ ACE inhibitors should be started and continued indefinitely in all patients with LVEF &lt;0.40 and in those with hypertension, diabetes mellitus, or stable CKD, unless contraindicated.</li> <li>○ ARBs are recommended in patients with heart failure or myocardial infarction with LVEF &lt;0.40 who are ACE inhibitor intolerant.</li> <li>○ Aldosterone-blockade is recommended in patients post-MI without significant renal dysfunction (creatinine &gt;2.5 mg/dL in men or &gt;2.0 mg/dL in women) or hyperkalemia (K &gt;5.0 mEq/L) who are receiving therapeutic doses of ACE inhibitor and <math>\beta</math>-blocker and have a LVEF &lt;0.40, diabetes mellitus, or heart failure.</li> </ul> </li> <li>• Initial antiplatelet/anticoagulant therapy in patients with definite or likely NSTEMI-ACS treated with an initial invasive or ischemia-guided strategy <ul style="list-style-type: none"> <li>○ Non-enteric coated, chewable aspirin (162 to 325 mg) should be given to all patients with NSTEMI-ACS without contraindications as soon as possible after presentation, and a maintenance dose of aspirin (81 to 162 mg/day) should be continued indefinitely.</li> <li>○ In patients who are unable to take aspirin because of hypersensitivity or major gastrointestinal intolerance, a loading dose of clopidogrel followed by a daily maintenance dose should be administered.</li> <li>○ A P2Y<sub>12</sub> receptor inhibitor (clopidogrel or ticagrelor) in addition to aspirin should be administered for up to 12 months to all patients with NSTEMI-ACS without contraindications who are treated with an early invasive or ischemia-guided strategy. Options include: <ul style="list-style-type: none"> <li>▪ Clopidogrel: 300 or 600 mg loading dose, then 75 mg daily.</li> <li>▪ Ticagrelor: 180 mg loading dose, then 90 mg twice daily.</li> <li>▪ It is reasonable to use ticagrelor in preference to clopidogrel for P2Y<sub>12</sub> treatment in patients with NSTEMI-ACS who undergo an early invasive or ischemia-guided strategy.</li> <li>▪ In patients with NSTEMI-ACS treated with an early invasive strategy and dual antiplatelet therapy (DAPT) with intermediate/high-risk features (e.g., positive troponin), a GP IIb/IIIa inhibitor may be considered as part of initial antiplatelet therapy. Preferred options are eptifibatid or tirofiban.</li> </ul> </li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p><u>Percutaneous coronary intervention (PCI)- Antiplatelet and anticoagulant therapy</u></p> <ul style="list-style-type: none"> <li>• Antiplatelet agents               <ul style="list-style-type: none"> <li>○ Patients already taking daily aspirin before PCI should take 81 to 325 mg non-enteric coated aspirin before PCI</li> <li>○ Patients not on aspirin therapy should be given non-enteric coated aspirin 325 mg as soon as possible before PCI.</li> <li>○ After PCI, aspirin should be continued indefinitely.</li> <li>○ A loading dose of a P2Y<sub>12</sub> inhibitor should be given before the procedure in patients undergoing PCI with stenting. Options include clopidogrel 600 mg, prasugrel 60 mg, or ticagrelor 180 mg.</li> <li>○ In patients with NSTEMI-ACS and high-risk features (e.g., elevated troponin) not adequately pretreated with clopidogrel or ticagrelor, it is useful to administer a GP IIb/IIIa inhibitor (abciximab, double-bolus eptifibatide, or high-dose bolus tirofiban) at the time of PCI.</li> <li>○ In patients receiving a stent (bare metal or drug eluting) during PCI, P2Y<sub>12</sub> inhibitor therapy should be given for at least 12 months. Options include clopidogrel 75 mg daily, prasugrel 10 mg daily, or ticagrelor 90 mg twice daily.</li> </ul> </li> <li>• Anticoagulant therapy               <ul style="list-style-type: none"> <li>○ An anticoagulant should be administered to patients with NSTEMI-ACS undergoing PCI to reduce the risk of intracoronary and catheter thrombus formation.</li> <li>○ Intravenous unfractionated heparin (UFH) is useful in patients with NSTEMI-ACS undergoing PCI.</li> <li>○ Bivalirudin is useful as an anticoagulant with or without prior treatment with UFH.</li> <li>○ An additional dose of 0.3 mg/kg intravenous enoxaparin should be administered at the time of PCI to patients with NSTEMI-ACS who have received fewer than two therapeutic subcutaneous doses or received the last subcutaneous enoxaparin dose eight to 12 hours before PCI.</li> <li>○ If PCI is performed while the patient is on fondaparinux, an additional 85 IU/kg of UFH should be given intravenously immediately before PCI because of the risk of catheter thrombosis (60 IU/kg IV if a GP IIb/IIIa inhibitor used with UFH dosing based on the target-activated clotting time).</li> <li>○ Anticoagulant therapy should be discontinued after PCI unless there is a compelling reason to continue.</li> </ul> </li> <li>• Timing of CABG in relation to use of antiplatelet agents               <ul style="list-style-type: none"> <li>○ Non-enteric coated aspirin (81 to 325 mg daily) should be administered preoperatively to patients undergoing CABG.</li> <li>○ In patients referred for elective CABG, clopidogrel and ticagrelor should be discontinued for at least five days before surgery and prasugrel for at least seven days before surgery.</li> <li>○ In patients referred for urgent CABG, clopidogrel and ticagrelor should be discontinued for at least 24 hours to reduce major bleeding.</li> <li>○ In patients referred for CABG, short-acting intravenous GP IIb/IIIa inhibitors (eptifibatide or tirofiban) should be discontinued for at least 2 to 4 hours before surgery and abciximab for at least 12 hours before to limit blood loss and transfusion.</li> </ul> </li> </ul> <p><u>Late hospital care, hospital discharge, and posthospital discharge care</u></p> <ul style="list-style-type: none"> <li>• Medications at discharge               <ul style="list-style-type: none"> <li>○ Medications required in the hospital to control ischemia should be continued after hospital discharge in patients with NSTEMI-ACS who do not undergo coronary revascularization, patients with incomplete or unsuccessful</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>revascularization, and patients with recurrent symptoms after revascularization. Titration of the doses may be required.</p> <ul style="list-style-type: none"> <li>○ All patients who are post–NSTEMI-ACS should be given sublingual or spray nitroglycerin with verbal and written instructions for its use.</li> <li>○ Before hospital discharge, patients with NSTEMI-ACS should be informed about symptoms of worsening myocardial ischemia and MI and should be given verbal and written instructions about how and when to seek emergency care for such symptoms.</li> <li>○ Before hospital discharge, patients who are post–NSTEMI-ACS and/or designated responsible caregivers should be provided with easily understood and culturally sensitive verbal and written instructions about medication type, purpose, dose, frequency, side effects, and duration of use.</li> <li>○ For patients who are post–NSTEMI-ACS and have initial angina lasting more than one minute, nitroglycerin (one dose sublingual or spray) is recommended if angina does not subside within three to five minutes; call 9-1-1 immediately to access emergency medical services.</li> <li>○ If the pattern or severity of angina changes, suggesting worsening myocardial ischemia (e.g., pain is more frequent or severe or is precipitated by less effort or occurs at rest), patients should contact their clinician without delay to assess the need for additional treatment or testing.</li> <li>○ Before discharge, patients should be educated about modification of cardiovascular risk factors.</li> </ul> <ul style="list-style-type: none"> <li>● Late hospital and post-hospital oral antiplatelet therapy <ul style="list-style-type: none"> <li>○ Aspirin should be continued indefinitely. The dose should be 81 mg daily in patients treated with ticagrelor and 81 to 325 mg daily in all other patients.</li> <li>○ In addition to aspirin, a P2Y<sub>12</sub> inhibitor (either clopidogrel or ticagrelor) should be continued for up to 12 months in all patients with NSTEMI-ACS without contraindications who are treated with an ischemia-guided strategy.</li> <li>○ In patients receiving a stent (bare-metal stent or DES) during PCI for NSTEMI-ACS, P2Y<sub>12</sub> inhibitor therapy should be given for at least 12 months.</li> </ul> </li> <li>● Combined oral anticoagulant therapy and antiplatelet therapy in patients with NSTEMI-ACS <ul style="list-style-type: none"> <li>○ The duration of triple antithrombotic therapy with a vitamin K antagonist, aspirin, and a P2Y<sub>12</sub> receptor inhibitor in patients with NSTEMI-ACS should be minimized to the extent possible to limit the risk of bleeding.</li> <li>○ Proton pump inhibitors should be prescribed in patients with NSTEMI-ACS with a history of gastrointestinal bleeding who require triple antithrombotic therapy with a vitamin K antagonist, aspirin, and a P2Y<sub>12</sub> receptor inhibitor.</li> </ul> </li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Management of Acute Coronary Syndromes in Patients Presenting without Persistent ST-Segment Elevation</b> (2020)<sup>22</sup></p>	<p><u>Pharmacological treatment of ischemia</u></p> <ul style="list-style-type: none"> <li>● Sublingual or intravenous nitrates and early initiation of <math>\beta</math>-blocker treatment is recommended in patients with ongoing ischemic symptoms and without contraindications.</li> <li>● Continuation of chronic <math>\beta</math>-blocker therapy is recommended unless the patient is in overt heart failure</li> <li>● Sublingual or intravenous nitrates are recommended to relieve angina; intravenous treatment is recommended in patients with recurrent angina, uncontrolled hypertension, or signs of heart failure.</li> <li>● In patients with suspected/confirmed vasospastic angina, calcium channel blockers, and nitrates should be considered and <math>\beta</math>-blockers avoided.</li> </ul> <p><u>Recommendations for platelet inhibition in non-ST-elevation acute coronary syndromes</u></p> <ul style="list-style-type: none"> <li>● Aspirin is recommended for all patients without contraindications at an initial oral loading dose of 150 to 300 mg (in aspirin-naïve patients) and a maintenance dose of 75 to 100 mg/day long-term regardless of treatment strategy.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• A P2Y<sub>12</sub> inhibitor is recommended, in addition to aspirin, for 12 months unless there are contraindications such as excessive risks of bleeds.               <ul style="list-style-type: none"> <li>○ Ticagrelor (180 mg loading dose, 90 mg twice daily) is recommended, in the absence of contraindication, for all patients at moderate-to-high risk of ischemic events (e.g., elevated cardiac troponins), regardless of initial treatment strategy and including those pretreated with clopidogrel (which should be discontinued when ticagrelor is started).</li> <li>○ Prasugrel (60 mg loading dose, 10 mg daily dose) is recommended in patients who are proceeding to PCI if no contraindication. Prasugrel should be considered in preference to ticagrelor in NSTEMI-ACS patients who proceed to PCI.</li> <li>○ Clopidogrel (300 to 600 mg loading dose, 75 mg daily dose) is recommended for patients who cannot receive ticagrelor or prasugrel or who require oral anticoagulation.</li> </ul> </li> <li>• P2Y<sub>12</sub> inhibitor administration for a shorter duration of three to six months after DES implantation may be considered in patients deemed at high bleeding risk.</li> <li>• Pre-treatment with a P2Y<sub>12</sub> inhibitor may be considered in patients with NSTEMI-ACS who are not planned to undergo an early invasive strategy.</li> <li>• It is not recommended to administer routine pre-treatment with a P2Y<sub>12</sub> inhibitor in patients in whom coronary anatomy is not known.</li> <li>• It is not recommended to administer prasugrel in patients whom coronary anatomy is not known.</li> <li>• GPIIb/IIIa inhibitors during PCI should be considered for bailout situations or thrombotic complications.</li> <li>• Cangrelor may be considered in P2Y<sub>12</sub> inhibitor-naïve patients undergoing PCI.</li> <li>• It is not recommended to administer GPIIb/IIIa inhibitors in patients whom coronary anatomy is not known.</li> <li>• P2Y<sub>12</sub> inhibitor administration in addition to aspirin beyond one year may be considered after careful assessment of the ischemic and bleeding risks of the patient.</li> </ul> <p><u>Recommendations for anticoagulation in non-ST-elevation acute coronary syndromes</u></p> <ul style="list-style-type: none"> <li>• Parenteral anticoagulation is recommended at the time of diagnosis according to both ischemic and bleeding risks.</li> <li>• Fondaparinux is recommended as having the most favorable efficacy-safety profile regardless of the management strategy.</li> <li>• Bivalirudin is recommended as an alternative to UFH plus GPIIb/IIIa inhibitors during PCI.</li> <li>• UFH is recommended in patients undergoing PCI who did not receive any anticoagulant.</li> <li>• In patients on fondaparinux undergoing PCI, a single intravenous bolus of UFH is recommended during the procedure.</li> <li>• Enoxaparin or UFH are recommended when fondaparinux is not available.</li> <li>• Enoxaparin should be considered as an anticoagulant for PCI in patients pretreated for PCI with subcutaneous enoxaparin.</li> <li>• Additional activated clotting time-guided intravenous boluses of UFH during PCI may be considered following initial UFH treatment.</li> <li>• Discontinuation of anticoagulation should be considered after PCI, unless otherwise indicated.</li> <li>• Crossover between UFH and LMWH is not recommended.</li> <li>• In NSTEMI patients with no prior stroke/TIA and at high ischemic risk as well as low bleeding risk receiving aspirin and clopidogrel, low-dose rivaroxaban (2.5 mg twice daily for approximately one year) may be considered after discontinuation of parenteral anticoagulation.</li> </ul>

Clinical Guideline	Recommendations
	<p><b>Recommendations for combining antiplatelet agents and anticoagulants in non-ST-elevation acute coronary syndrome patients requiring chronic oral anticoagulation</b></p> <ul style="list-style-type: none"> <li>• In patients with a firm indication for oral anticoagulation (e.g., atrial fibrillation with a CHADS<sub>2</sub>-VASc score <math>\geq 2</math>, recent VTE, mechanical valve prosthesis), oral anticoagulation is recommended in addition to antiplatelet therapy.</li> <li>• An early invasive coronary angiography (within 24 hours) should be considered in moderate- to high-risk patients, irrespective of oral anticoagulant exposure, to expedite treatment allocation (medical vs PCI vs CABG) and to determine optimal antithrombotic regimen.</li> <li>• Initial dual antiplatelet therapy with aspirin plus a P2Y<sub>12</sub> inhibitor in addition to oral anticoagulation before coronary angiography is not recommended.</li> <li>• During PCI, additional parenteral anticoagulation is recommended, irrespective of the timing of the last dose of all non-vitamin K antagonist oral anticoagulants (NOACs) and if INR is <math>&lt; 2.5</math> in VKA-treated patients.</li> <li>• Uninterrupted therapeutic anticoagulation with VKA or NOACs should be considered during the periprocedural phase.</li> <li>• Periprocedural DAPT administration consisting of aspirin and clopidogrel up to one week is recommended</li> <li>• Discontinuation of antiplatelet treatment in patients treated with an oral anticoagulant is recommended after 12 months</li> <li>• Following coronary stenting, dual (oral) antiplatelet therapy (DAPT) including new P2Y<sub>12</sub> inhibitors should be considered as an alternative to triple therapy for patients with non-ST-elevation acute coronary syndromes and atrial fibrillation with a CHADS<sub>2</sub>-VASc score of 1 (in males) or 2 (in females).</li> <li>• If at low bleeding risk (HAS-BLED <math>\leq 2</math>), triple therapy with oral anticoagulant, aspirin, and clopidogrel should be considered for six months, followed by oral anticoagulant and aspirin or clopidogrel continued up to 12 months.</li> <li>• If at high bleeding risk (HAS-BLED <math>\geq 3</math>), triple therapy with oral anticoagulant, aspirin, and clopidogrel should be considered for one month, followed by oral anticoagulant and aspirin or clopidogrel continued up to 12 months irrespective of the stent type.</li> <li>• Dual therapy with oral anticoagulant and clopidogrel may be considered as an alternative to triple antithrombotic therapy in selected patients (HAS-BLED <math>\geq 3</math> and low risk of stent thrombosis).</li> <li>• The use of ticagrelor or prasugrel as part of triple therapy is not recommended.</li> <li>• In medically managed patients, one antiplatelet agent in addition to oral anticoagulant should be considered for up to one year.</li> </ul> <p><b>Recommendations for post-interventional and maintenance treatment</b></p> <ul style="list-style-type: none"> <li>• In patients with NSTEMI-ACS with coronary stent implantation, DAPT with a P2Y<sub>12</sub> inhibitor on top of aspirin is recommended for 12 months unless there are contraindications such as excessive risk of bleeding.</li> <li>• Adding a second anti-thrombotic agent to aspirin for extended long-term secondary prevention should be considered in patients with a moderate to high risk of ischemic events and without increased risk of major bleeding.</li> <li>• After stent implantation with high risk of bleeding, discontinuation of P2Y<sub>12</sub> inhibitor therapy after three months should be considered</li> <li>• After stent implantation in patients undergoing DAPT, stopping aspirin after three to six months should be considered, depending on balance between ischemic and bleeding risk.</li> <li>• De-escalation of P2Y<sub>12</sub> inhibitor treatment may be considered as an alternative DAPT strategy, especially for ACS patients deemed unsuitable for potent platelet inhibition.</li> </ul>

Clinical Guideline	Recommendations
<p>American College of Cardiology/American Heart Association: <b>Guideline for the Management of ST-Elevation Myocardial Infarction (2013)</b><sup>23</sup></p>	<p><u>Routine medical therapies: calcium channel blockers</u></p> <ul style="list-style-type: none"> <li>Evidence demonstrates that beneficial effect on infarct size or the rate of reinfarction when calcium channel blocker therapy was initiated during either the acute or convalescent phase of ST-segment elevation myocardial infarction (STEMI). However, calcium channel blockers may be useful to relieve ischemia, lower blood pressure, or control the ventricular response rate to atrial fibrillation in patients who are intolerant to <math>\beta</math>-blockers.</li> <li>Use of immediate-release nifedipine is contraindicated in patients with STEMI due to hypotension and reflex sympathetic activation with tachycardia.</li> </ul> <p><u>Routine medical therapies: <math>\beta</math>-blockers</u></p> <ul style="list-style-type: none"> <li>Oral <math>\beta</math>-blockers should be initiated within the first 24 hours in patients with an ST-segment elevation myocardial infarction (STEMI) who do not have any of the following: 1) signs of heart failure, 2) evidence of a low-output state, 3) increased risk of cardiogenic shock, 4) other contraindications to use of oral <math>\beta</math>-blockers (e.g., PR interval &gt;24 seconds, second or third degree heart block, active asthma, reactive airway disease).</li> <li><math>\beta</math>-blockers should be continued during and after hospitalization for all patients with STEMI and with no contraindications to their use.</li> <li>Patients with initial contraindications to the use of <math>\beta</math>-blockers in the first 24 hours after STEMI should be re-evaluated to determine their subsequent eligibility.</li> <li>It is reasonable to administer intravenous <math>\beta</math>-blockers at the time of presentation to patients with STEMI and no contraindications to their use who are hypertensive or have ongoing ischemia.</li> </ul> <p><u>Routine medical therapies: Renin-Angiotensin-Aldosterone System Inhibitors</u></p> <ul style="list-style-type: none"> <li>An angiotensin-converting enzyme (ACE) inhibitor should be administered within the first 24 hours to all patients with STEMI with anterior location, HF, or ejection fraction (EF) <math>\leq 40\%</math>, unless contraindicated.</li> <li>An angiotensin receptor blocker (ARB) should be given to patients with STEMI who have indications for but are intolerant of ACE inhibitors.</li> <li>An aldosterone antagonist should be given to patients with STEMI and no contraindications who are already receiving an ACE inhibitor and <math>\beta</math>-blocker and who have an EF <math>\leq 40\%</math> and either symptomatic heart failure or diabetes.</li> </ul> <p><u>Routine medical therapies: Lipid management</u></p> <ul style="list-style-type: none"> <li>High-intensity statin therapy should be initiated or continued in all patients with STEMI and no contraindications to its use.</li> <li>It is reasonable to obtain a fasting lipid profile in patients with STEMI, preferably within 24 hours of presentation.</li> </ul>
<p>European Society of Cardiology: <b>Management of Acute Myocardial Infarction in Patients Presenting with ST-segment Elevation (2017)</b><sup>24</sup></p>	<p><u>Routine therapies in the acute, subacute and long term phase of ST-elevation myocardial infarction (STEMI)</u></p> <ul style="list-style-type: none"> <li>Antiplatelet therapy with low dose aspirin (75 to 100 mg) is indicated indefinitely after STEMI.</li> <li>Dual antiplatelet therapy with a combination of aspirin and prasugrel or aspirin and ticagrelor is recommended for 12 months after percutaneous coronary intervention (PCI), unless there are contraindications such as excessive risk of bleeding.</li> <li>A proton pump inhibitor (PPI) in combination with dual antiplatelet therapy is recommended in patients at high risk of gastrointestinal bleeding.</li> <li>In patients with an indication for oral anticoagulation, oral anticoagulants are indicated in addition to antiplatelet therapy.</li> <li>In patients who are at high risk of severe bleeding complications, discontinuation of P2Y<sub>12</sub> inhibitor therapy after six months should be considered.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In STEMI patients with stent implantation and an indication for oral anticoagulation, triple therapy (oral anticoagulant, aspirin, and clopidogrel) should be considered for one to six months (according a balance between the estimated risk of recurrent coronary events and bleeding).</li> <li>• In patients with left ventricular thrombus, anticoagulation should be instituted for a minimum of six months, guided by repeated imaging.</li> <li>• In selected patients who receive aspirin and clopidogrel, low-dose rivaroxaban (2.5 mg twice daily) may be considered if the patient is at low bleeding risk.</li> <li>• Dual antiplatelet therapy should be used up to one year in patients with STEMI who did not receive a stent unless there are contraindications such as excessive risk of bleeding.</li> <li>• In high ischemic-risk patients (age <math>\geq 50</math> years, and at least one of the following risk factors: age <math>\geq 65</math> years, diabetes mellitus on medication, prior spontaneous MAI, multivessel CAD, or chronic renal dysfunction with eGFR <math>&lt; 60</math> mL/min) who have tolerated dual antiplatelet therapy without a bleeding complication, treatment with dual antiplatelet therapy in the form of ticagrelor 60 mg twice a day on top of aspirin for longer than 12 months may be considered for up to three years.</li> <li>• The use of ticagrelor or prasugrel is not recommended as part of triple antithrombotic therapy with aspirin and oral anticoagulation.</li> <li>• Oral treatment with <math>\beta</math>-blockers should be considered during hospital stay and continued thereafter in all patients without contraindications.</li> <li>• Oral treatment with <math>\beta</math>-blockers is indicated in patients with heart failure or left ventricular dysfunction, LVEF <math>\leq 40\%</math> unless contraindicated.</li> <li>• Intravenous <math>\beta</math>-blockers must be avoided in patients with hypotension or acute heart failure or AV block or severe bradycardia.</li> <li>• Intravenous <math>\beta</math>-blockers should be considered at the time of presentation in patients undergoing primary PCI without contraindications, with high blood pressure, tachycardia, and no signs of heart failure.</li> <li>• A fasting lipid profile must be obtained in all STEMI patients, as soon as possible after presentation.</li> <li>• It is recommended to initiate or continue high dose statins early after admission in all STEMI patients without contraindication or history of intolerance, regardless of initial cholesterol values and maintain it long-term.</li> <li>• An LDL-C goal of <math>&lt; 1.8</math> mmol/L (70 mg/dL) or a reduction of at least 50% if the baseline LDL-C is between 1.8 to 3.5 mmol/L (70 to 135 mg/dL) is recommended.</li> <li>• In patients with LDL-C <math>&gt; 1.8</math> mmol/L (<math>&gt; 70</math> mg/dL) despite a maximally tolerated statin dose who remain at high risk, further therapy to reduce LDL-C should be considered.</li> <li>• ACE inhibitors are indicated starting within the first 24 hours of STEMI in patients with evidence of heart failure, LV systolic dysfunction, diabetes or an anterior infarct.</li> <li>• An ARB, preferably valsartan, is an alternative to ACE inhibitors in patients with heart failure or LV systolic dysfunction, particularly those who are intolerant to ACE inhibitors.</li> <li>• ACE inhibitors should be considered in all patients in the absence of contraindications.</li> <li>• Aldosterone antagonists, e.g. eplerenone, are indicated in patients with an ejection fraction <math>\leq 40\%</math> and heart failure or diabetes, provided no renal failure or hyperkalemia.</li> </ul>
American College of Cardiology/ American Heart Association:	<p><u>Top 10 messages for the primary prevention of cardiovascular disease</u></p> <ul style="list-style-type: none"> <li>• The most important way to prevent atherosclerotic vascular disease, heart failure, and atrial fibrillation is to promote a healthy lifestyle throughout life.</li> </ul>

Clinical Guideline	Recommendations
<p><b>Guideline on the Primary Prevention of Cardiovascular Disease (2019)</b><sup>25</sup></p>	<ul style="list-style-type: none"> <li>• A team-based care approach is an effective strategy for the prevention of cardiovascular disease. Clinicians should evaluate the social determinants of health that affect individuals to inform treatment decisions.</li> <li>• Adults who are 40 to 75 years of age and are being evaluated for cardiovascular disease prevention should undergo 10-year atherosclerotic cardiovascular disease (ASCVD) risk estimation and have a clinician–patient risk discussion before starting on pharmacological therapy, such as antihypertensive therapy, a statin, or aspirin. In addition, assessing for other risk-enhancing factors can help guide decisions about preventive interventions in select individuals, as can coronary artery calcium scanning.</li> <li>• All adults should consume a healthy diet that emphasizes the intake of vegetables, fruits, nuts, whole grains, lean vegetable or animal protein, and fish and minimizes the intake of trans fats, processed meats, refined carbohydrates, and sweetened beverages. For adults with overweight and obesity, counseling and caloric restriction are recommended for achieving and maintaining weight loss.</li> <li>• Adults should engage in at least 150 minutes per week of accumulated moderate-intensity physical activity or 75 minutes per week of vigorous-intensity physical activity.</li> <li>• For adults with type 2 diabetes mellitus, lifestyle changes, such as improving dietary habits and achieving exercise recommendations, are crucial. If medication is indicated, metformin is first-line therapy, followed by consideration of a sodium-glucose cotransporter 2 inhibitor or a glucagon-like peptide-1 receptor agonist.</li> <li>• All adults should be assessed at every healthcare visit for tobacco use, and those who use tobacco should be assisted and strongly advised to quit.</li> <li>• Aspirin should be used infrequently in the routine primary prevention of ASCVD because of lack of net benefit.</li> <li>• Statin therapy is first-line treatment for primary prevention of ASCVD in patients with elevated low-density lipoprotein cholesterol levels (<math>\geq 190</math> mg/dL), those with diabetes mellitus, who are 40 to 75 years of age, and those determined to be at sufficient ASCVD risk after a clinician–patient risk discussion.</li> <li>• Nonpharmacological interventions are recommended for all adults with elevated blood pressure or hypertension. For those requiring pharmacological therapy, the target blood pressure should generally be <math>&lt; 130/80</math> mm Hg.</li> </ul> <p><u>Adults with Type 2 Diabetes Mellitus</u></p> <ul style="list-style-type: none"> <li>• For all adults with T2DM, a tailored nutrition plan focusing on a heart-healthy dietary pattern is recommended to improve glycemic control, achieve weight loss if needed, and improve other ASCVD risk factors.</li> <li>• Adults with T2DM should perform at least 150 minutes per week of moderate-intensity physical activity or 75 minutes of vigorous-intensity physical activity to improve glycemic control, achieve weight loss if needed, and improve other ASCVD risk factors.</li> <li>• For adults with T2DM, it is reasonable to initiate metformin as first-line therapy along with lifestyle therapies at the time of diagnosis to improve glycemic control and reduce ASCVD risk.</li> <li>• For adults with T2DM and additional ASCVD risk factors who require glucose-lowering therapy despite initial lifestyle modifications and metformin, it may be reasonable to initiate a sodium-glucose cotransporter 2 (SGLT-2) inhibitor or a glucagon-like peptide-1 receptor (GLP-1R) agonist to improve glycemic control and reduce CVD risk.</li> </ul> <p><u>Adults with high blood cholesterol</u></p> <ul style="list-style-type: none"> <li>• In adults at intermediate risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk), statin therapy reduces risk of ASCVD, and in the context of a risk discussion, if a</li> </ul>

Clinical Guideline	Recommendations
	<p>decision is made for statin therapy, a moderate-intensity statin should be recommended.</p> <ul style="list-style-type: none"> <li>• In intermediate risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk) patients, LDL-C levels should be reduced by 30% or more, and for optimal ASCVD risk reduction, especially in patients at high risk (<math>\geq 20\%</math> 10-year ASCVD risk), levels should be reduced by 50% or more.</li> <li>• In adults 40 to 75 years of age with diabetes, regardless of estimated 10-year ASCVD risk, moderate-intensity statin therapy is indicated.</li> <li>• In patients 20 to 75 years of age with an LDL-C level of 190 mg/dL (<math>\geq 4.9</math> mmol/L) or higher, maximally tolerated statin therapy is recommended.</li> <li>• In adults with diabetes mellitus who have multiple ASCVD risk factors, it is reasonable to prescribe high-intensity statin therapy with the aim to reduce LDL-C levels by 50% or more.</li> <li>• In intermediate-risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk) adults, risk-enhancing factors favor initiation or intensification of statin therapy.</li> <li>• In intermediate-risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk) adults or selected borderline-risk (5% to <math>&lt; 7.5\%</math> 10-year ASCVD risk) adults in whom a coronary artery calcium score is measured for the purpose of making a treatment decision, AND <ul style="list-style-type: none"> <li>○ If the coronary artery calcium score is zero, it is reasonable to withhold statin therapy and reassess in five to 10 years, as long as higher-risk conditions are absent (e.g., diabetes, family history of premature CHD, cigarette smoking);</li> <li>○ If coronary artery calcium score is one to 99, it is reasonable to initiate statin therapy for patients <math>\geq 55</math> years of age;</li> <li>○ If coronary artery calcium score is 100 or higher or in the 75th percentile or higher, it is reasonable to initiate statin therapy.</li> </ul> </li> <li>• In patients at borderline risk (5% to <math>&lt; 7.5\%</math> 10-year ASCVD risk), in risk discussion, the presence of risk-enhancing factors may justify initiation of moderate-intensity statin therapy.</li> </ul> <p><u>Adults with high blood pressure or hypertension</u></p> <ul style="list-style-type: none"> <li>• In adults with elevated blood pressure (BP) or hypertension, including those requiring antihypertensive medications nonpharmacological interventions are recommended to reduce BP. These include: <ul style="list-style-type: none"> <li>○ weight loss;</li> <li>○ a heart-healthy dietary pattern;</li> <li>○ sodium reduction;</li> <li>○ dietary potassium supplementation;</li> <li>○ increased physical activity with a structured exercise program; and</li> <li>○ limited alcohol.</li> </ul> </li> <li>• In adults with an estimated 10-year ASCVD risk (ACC/AHA pooled cohort equations to estimate 10-year risk of ASCVD) of 10% or higher and an average systolic BP (SBP) of 130 mm Hg or higher or an average diastolic BP (DBP) of 80 mm Hg or higher, use of BP-lowering medications is recommended for primary prevention of CVD.</li> <li>• In adults with confirmed hypertension and a 10-year ASCVD event risk of 10% or higher, a BP target of less than 130/80 mm Hg is recommended.</li> <li>• In adults with hypertension and chronic kidney disease, treatment to a BP goal of less than 130/80 mm Hg is recommended.</li> <li>• In adults with T2DM and hypertension, antihypertensive drug treatment should be initiated at a BP of 130/80 mm Hg or higher, with a treatment goal of less than 130/80 mm Hg.</li> <li>• In adults with an estimated 10-year ASCVD risk <math>&lt; 10\%</math> and an SBP of 140 mm Hg or higher or a DBP of 90 mm Hg or higher, initiation and use of BP-lowering</li> </ul>

Clinical Guideline	Recommendations
	<p>medication are recommended.</p> <ul style="list-style-type: none"> <li>In adults with confirmed hypertension without additional markers of increased ASCVD risk, a BP target of less than 130/80 mm Hg may be reasonable.</li> </ul> <p><u>Recommendations for treatment of tobacco use</u></p> <ul style="list-style-type: none"> <li>All adults should be assessed at every healthcare visit for tobacco use and their tobacco use status recorded as a vital sign to facilitate tobacco cessation.</li> <li>To achieve tobacco abstinence, all adults who use tobacco should be firmly advised to quit.</li> <li>In adults who use tobacco, a combination of behavioral interventions plus pharmacotherapy is recommended to maximize quit rates.</li> <li>In adults who use tobacco, tobacco abstinence is recommended to reduce ASCVD risk.</li> <li>To facilitate tobacco cessation, it is reasonable to dedicate trained staff to tobacco treatment in every healthcare system.</li> <li>All adults and adolescents should avoid secondhand smoke exposure to reduce ASCVD risk.</li> </ul> <p><u>Recommendations for aspirin use</u></p> <ul style="list-style-type: none"> <li>Low-dose aspirin (75 to 100 mg orally daily) might be considered for the primary prevention of ASCVD among select adults 40 to 70 years of age who are at higher ASCVD risk but not at increased bleeding risk.</li> <li>Low-dose aspirin (75 to 100 mg orally daily) should not be administered on a routine basis for the primary prevention of ASCVD among adults &gt;70 years of age.</li> <li>Low-dose aspirin (75 to 100 mg orally daily) should not be administered for the primary prevention of ASCVD among adults of any age who are at increased risk of bleeding.</li> </ul>
<p>American Heart Association/American College of Cardiology/Heart Failure Society of America: 2022 AHA/ACC/HFSA Guideline for the Management of Heart Failure (2022)<sup>26</sup></p>	<p><u>Treatment of Stage A heart failure (HF)</u></p> <ul style="list-style-type: none"> <li>Hypertension should be controlled in accordance with guideline-directed medication therapy for hypertension to prevent symptomatic HF. (LoE: A)</li> <li>In patients with type 2 diabetes and either established CVD or at high cardiovascular risk, SGLT-2 inhibitors should be used to prevent hospitalizations for HF. (LoE: A)</li> <li>In the general population, healthy lifestyle habits such as regular physical activity, maintaining normal weight, healthy dietary patterns, and avoiding smoking are helpful to reduce future risk of HF. (LoE: B)</li> <li>Patients at risk of developing HF, natriuretic peptide biomarker-based screening followed by team-based care, including a cardiovascular specialist optimizing therapy, can be useful to prevent the development of LV dysfunction (systolic or diastolic) or new-onset HF. (LoE: B)</li> </ul> <p><u>Treatment of Stage B heart failure</u></p> <ul style="list-style-type: none"> <li>In patients with LVEF≤40%, ACE inhibitors should be used to prevent HF and reduce mortality. (LoE: A)</li> <li>In patients with a recent or remote history of MI or ACS, statins should be used to prevent symptomatic HF and adverse cardiovascular events. (LoE: A)</li> <li>In patients with a recent MI and LVEF≤40% who are intolerant to ACE inhibitors, ARB should be used to prevent symptomatic HF and reduce mortality. (LoE: B)</li> <li>In patients with a recent or remote history of MI or ACS and LVEF≤40%, evidence-based beta blockers should be used to reduce mortality. (LoE: B)</li> <li>In patients who are at least 40 days post-MI with LVEF ≤30% and NYHA class I symptoms while receiving guideline-directed medication therapy and have</li> </ul>

Clinical Guideline	Recommendations
	<p>reasonable expectation of meaningful survival for greater than one year, an implantable cardioverter-defibrillator is recommended for primary prevention of sudden cardiac death to reduce total mortality. (LoE: B)</p> <ul style="list-style-type: none"> <li>• In patients with LVEF <math>\leq 40\%</math>, beta blockers should be used to prevent symptomatic HF. (LoE: C)</li> <li>• In patients with LVEF <math>\leq 50\%</math>, thiazolidinediones should not be used because they increase the risk of HF, including hospitalizations. (LoE: B)</li> <li>• In patients with LVEF <math>\leq 50\%</math>, nondihydropyridine calcium channel blockers with negative inotropic effects may be harmful. (LoE: C)</li> </ul> <p><b>Treatment for Stage C Heart Failure with Reduced Ejection Fraction (HFrEF)</b></p> <ul style="list-style-type: none"> <li>• For patients with stage C HF, avoiding excessive sodium intake is reasonable to reduce congestive symptoms. (LoE: C)</li> <li>• In patients with HF who have fluid retention, diuretics are recommended to relieve congestion, improve symptoms, and prevent worsening HF. (LoE: B)</li> <li>• For patients with HF and congestive symptoms, addition of a thiazide (e.g., metolazone) to treatment with a loop diuretic should be reserved for patients who do not respond to moderate or high dose loop diuretics to minimize electrolyte abnormalities. (LoE: B)</li> <li>• In patients with HFrEF and NYHA class II to III symptoms, the use of an ARNI is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, the use of an ACE inhibitor is beneficial to reduce morbidity and mortality when the use of an ARNI is not feasible. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, who are intolerant to an ACE inhibitor because of cough or angioedema, and when the use of an ARNI is not feasible, the use of an ARB is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with chronic symptomatic HFrEF NYHA class II or III who tolerate an ACE inhibitor or ARB, replacement by an ARNI is recommended to further reduce morbidity and mortality. (LoE: B)</li> <li>• ARNIs should not be administered concomitantly with ACE inhibitors or within 36 hours of the last dose of an ACE inhibitor. (LoE: B)</li> <li>• ARNI or ACE inhibitors should not be administered in patients with a history of angioedema. (LoE: C)</li> <li>• In patients with HFrEF, with current or previous symptoms, use of one of the three <math>\beta</math>-blockers proven to reduce mortality (e.g., bisoprolol, carvedilol, sustained-release metoprolol succinate) is recommended to reduce mortality and hospitalizations. (LoE: A)</li> <li>• In patients with HFrEF and NYHA class II to IV symptoms, a mineralocorticoid receptor antagonist (spironolactone or eplerenone) is recommended to reduce morbidity and mortality, if eGFR is <math>&gt;30</math> mL/min/1.73 m<sup>2</sup> and serum potassium is <math>&lt;5.0</math> mEq/L. Careful monitoring of potassium, renal function, and diuretic dosing should be performed at initiation and closely followed thereafter to minimize risk of hyperkalemia and renal insufficiency. (LoE: A)</li> <li>• In patients taking a mineralocorticoid receptor antagonist whose serum potassium cannot be maintained at <math>&lt;5.5</math> mEq/L, mineralocorticoid receptor antagonist should be discontinued to avoid life threatening hyperkalemia. (LoE: B)</li> <li>• In patients with symptomatic chronic HFrEF, SGLT-2 an inhibitor is recommended to reduce hospitalization for HF and cardiovascular mortality, irrespective of the presence of type 2 diabetes. (LoE: A)</li> <li>• The combination of hydralazine and isosorbide dinitrate is recommended to improve symptoms and reduce morbidity and mortality for patients self-identified as African Americans with NYHA class III to IV HFrEF receiving optimal</li> </ul>

Clinical Guideline	Recommendations
	<p>therapy. (LoE: A)</p> <ul style="list-style-type: none"> <li>• In patients with current or previous symptomatic HFrEF who cannot be given first-line agents, such as an ARNI, ACE inhibitor or ARB because of drug intolerance or renal insufficiency, a combination of hydralazine and isosorbide dinitrate might be considered to reduce morbidity and mortality. (LoE: C)</li> <li>• In patients with HF class II to IV symptoms, omega-3 polyunsaturated fatty acid supplementation may be reasonable to use as adjunctive therapy to reduce mortality and cardiovascular hospitalizations. (LoE: B)</li> <li>• In patients with chronic HFrEF without specific indication (e.g., venous thromboembolism, atrial fibrillation, a previous thromboembolic event, or a cardioembolic source, anticoagulation is not recommended. (LoE: B)</li> <li>• Dihydropyridine and non-dihydropyridine calcium channel blockers are not recommended for patients with HFrEF. (LoE: A)</li> <li>• In patients with HFrEF, vitamins, nutritional supplements, and hormonal therapy are not recommended other than to correct specific deficiencies. (LoE: B)</li> <li>• In patients with HFrEF, class IC antiarrhythmic medication and dronedarone may increase risk of mortality. (LoE: A)</li> <li>• In patients with HFrEF, thiazolidinediones increase the risk of worsening HF symptoms and hospitalizations. (LoE: A)</li> <li>• In patients with type 2 diabetes and high cardiovascular risk, the DPP-4 inhibitors, saxagliptin and alogliptin, increase the risk of HF hospitalization and should be avoided in patients with HF. (LoE: B)</li> <li>• In patients with HFrEF, nonsteroidal anti-inflammatory drugs worsen HF symptoms and should be avoided or withdrawn whenever possible. (LoE: B)</li> <li>• For patients with symptomatic (NYHA class II to III) stable chronic HFrEF (LVEF <math>\leq 35\%</math>) who are receiving guideline-directed medical therapy, including a maximally tolerated dose of a beta blocker, and who are in sinus rhythm with a heart rate of <math>\geq 70</math> beats per minute at rest, ivabradine can be beneficial to reduce HF hospitalizations and cardiovascular death. (LoE: B)</li> <li>• In patients with symptomatic HFrEF despite guideline-directed medical therapy or who are unable to tolerate guideline-directed medical therapy, digoxin might be considered to decrease hospitalizations for HF. (LoE: B)</li> <li>• In select high-risk patients with HFrEF and recent worsening of HF already on guideline-directed medical therapy, an oral soluble guanylate cyclase stimulator (vericiguat) may be considered to reduce HF hospitalization and cardiovascular death. (LoE: B)</li> </ul> <p><u>Pharmacological treatment for Stage C HF with mildly reduced EF and improved EF</u></p> <ul style="list-style-type: none"> <li>• In patients with HF with mildly reduced EF, SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• Among patients with current or previous symptomatic HF with mildly reduced EF (LVEF, 41 to 49%), use of evidence-based beta blockers for HFrEF, ARNI, ACE inhibitor or ARB, and mineralocorticoid receptor antagonists may be considered to reduce the risk of HF hospitalization and cardiovascular mortality, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• In patients with HF with improved EF after treatment, guideline-directed medical therapy should be continued to prevent relapse of HF and LV dysfunction, even in patients who may become asymptomatic. (LoE: B)</li> </ul> <p><u>Pharmacological treatment for Stage C HF with preserved EF (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• Patients with hypertension and HFpEF should have medication titrated to attain blood pressure targets in accordance with published clinical practice guidelines to prevent morbidity. (LoE: C)</li> <li>• SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and</li> </ul>

Clinical Guideline	Recommendations
	<p>cardiovascular mortality. (LoE: B)</p> <ul style="list-style-type: none"> <li>In patients with HFpEF, the use of a mineralocorticoid receptor antagonist, ARB, or ARNI may be considered to decrease hospitalizations, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>Routine use of nitrates or phosphodiesterase-5 inhibitors to increase activity or quality of life in patients with HFpEF is ineffective. (LoE: B)</li> </ul> <p><b>Treatment of Stage D (advanced/refractory) HF</b></p> <ul style="list-style-type: none"> <li>For patients with advanced HF and hyponatremia, the benefit of fluid restriction to reduce congestive symptoms is uncertain. (LoE: C)</li> <li>Continuous intravenous inotropic support is reasonable as “bridge therapy” in patients with HF (Stage D) refractory to guideline-directed medical therapy and device therapy who are eligible for and awaiting mechanical circulatory support or cardiac transplantation. (LoE: B)</li> <li>In select patients with HF Stage D, despite optimal guideline-directed medical therapy and device therapy who are ineligible for either mechanical circulatory support or cardiac transplantation, continuous intravenous inotropic support may be considered as palliative therapy for symptom control and improvement in functional status. (LoE: B)</li> <li>Long-term use of either continuous or intermittent, intravenous inotropic agents, for reasons other than palliative care or as a bridge to advanced therapies, is potentially harmful. (LoE: B)</li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure (2021)</b><sup>27</sup></p>	<p><b>Pharmacological treatments indicated in patients with (NYHA Class II-IV) heart failure with reduced ejection fraction</b></p> <ul style="list-style-type: none"> <li>An ACE inhibitor is recommended, in addition to a <math>\beta</math>-blocker, for symptomatic patients with HF<sub>r</sub>EF to reduce the risk of HF hospitalization and death.</li> <li>A mineralocorticoid receptor antagonist (MRA) is recommended for patients with HF<sub>r</sub>EF, who remain symptomatic despite treatment with an ACE inhibitor and a <math>\beta</math>-blocker, to reduce the risk of HF hospitalization and death.</li> <li>Dapagliflozin or empagliflozin are recommended for patients with HF<sub>r</sub>EF to reduce the risk of HF hospitalization and death. Dapagliflozin or empagliflozin are recommended, in addition to optimal medical therapy with an ACE-I/ARNI, a <math>\beta</math>-blocker and an MRA, for patients with HF<sub>r</sub>EF regardless of diabetes status.</li> <li>Sacubitril-valsartan is recommended as a replacement for an ACE inhibitor to further reduce the risk of HF hospitalization and death in ambulatory patients with HF<sub>r</sub>EF who remain symptomatic despite optimal treatment with an ACE inhibitor, a <math>\beta</math>-blocker, and a mineralocorticoid receptor antagonist.</li> <li>Diuretics are recommended in order to improve symptoms and exercise capacity in patients with signs and/or symptoms of congestion.</li> <li>Ivabradine should be considered to reduce the risk of HF hospitalization or cardiovascular death in symptomatic patients with LVEF <math>\leq</math>35%, in sinus rhythm and a resting heart rate <math>\geq</math>70 bpm despite treatment with an evidence-based dose of <math>\beta</math>-blocker (or maximum tolerated dose below that), ACE inhibitor (or ARB), and a mineralocorticoid receptor antagonist (or ARB).</li> <li>Ivabradine should be considered to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients with LVEF <math>\leq</math>35%, in sinus rhythm and a resting heart rate <math>\geq</math>70 bpm who are unable to tolerate or have contraindications for a <math>\beta</math>-blocker. Patients should also receive an ACE inhibitor (or ARB) and a mineralocorticoid receptor antagonist (or ARB).</li> <li>An ARB is recommended to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients unable to tolerate an ACE inhibitor (patients should also receive a <math>\beta</math>-blocker and mineralocorticoid receptor antagonist).</li> <li>An ARB may be considered to reduce the risk of HF hospitalization and death in</li> </ul>

Clinical Guideline	Recommendations
	<p>patients who are symptomatic despite treatment with a <math>\beta</math>-blocker who are unable to tolerate a mineralocorticoid receptor antagonist.</p> <ul style="list-style-type: none"> <li>• Vericiguat may be considered in NYHA class II-IV who have had worsening HF despite treatment with an ACE-I (or ARNI), a <math>\beta</math>-blocker and an MRA to reduce the risk of CV mortality or HF hospitalization.</li> <li>• Hydralazine and isosorbide dinitrate should be considered in self-identified black patients with LVEF <math>\leq 35\%</math> or with an LVEF <math>&lt; 45\%</math> combined with a dilated LV in NYHA Class III-IV despite treatment with an ACE-I a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist to reduce the risk of HF hospitalization and death.</li> <li>• Hydralazine and isosorbide dinitrate may be considered in symptomatic patients with HFrEF who can tolerate neither an ACE inhibitor nor an ARB (or they are contraindicated) to reduce the risk of death.</li> <li>• Digoxin is a treatment with less-certain benefits and may be considered in symptomatic patients in sinus rhythm despite treatment with an ACE inhibitor (or ARB), a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist, to reduce the risk of hospitalization (both all-cause and HF-hospitalizations).</li> </ul> <p><u>Recommendations for treatment of patients with (NYHA class II-IV) heart failure with mildly reduced ejection fraction (HFmrEF)</u></p> <ul style="list-style-type: none"> <li>• Diuretics are recommended in patients with congestion and HFmrEF in order to alleviate symptoms and signs.</li> <li>• An ACE inhibitor may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An ARB may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• A <math>\beta</math>-blocker may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An MRA may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• Sacubitril/valsartan may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> </ul> <p><u>Recommendations for treatment of patients with heart failure with preserved ejection fraction (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• It is recommended to screen patients with HFpEF for both cardiovascular and noncardiovascular comorbidities, which, if present, should be treated provided safe and effective interventions exist to improve symptoms, well-being and/or prognosis.</li> <li>• Diuretics are recommended in congested patients with HFpEF in order to alleviate symptoms and signs.</li> </ul> <p><u>Recommendations for the primary prevention of heart failure in patients with risk factors for its development</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension is recommended to prevent or delay the onset of HF and prolong life.</li> <li>• Treatment with statins is recommended in patients at high risk of CV disease or with CV disease in order to prevent or delay the onset of HF, and to prevent HF hospitalizations.</li> <li>• SGLT2 inhibitors (canagliflozin, dapagliflozin, empagliflozin, ertugliflozin, sotagliflozin) are recommended in patients with diabetes at high risk of CV disease or with CV disease in order to prevent HF hospitalizations.</li> <li>• Counselling against sedentary habit, obesity, cigarette smoking, and alcohol abuse is recommended to prevent or delay the onset of HF.</li> </ul>

Clinical Guideline	Recommendations
	<p><b>Recommendations for the initial management of patients with acute heart failure – pharmacotherapy</b></p> <ul style="list-style-type: none"> <li>• Intravenous loop diuretics are recommended for all patients with acute HF admitted with signs/symptoms of fluid overload to improve symptoms. It is recommended to regularly monitor symptoms, urine output, renal function and electrolytes during use of intravenous diuretics.</li> <li>• Combination of a loop diuretic with thiazide type diuretic should be considered in patients with resistant oedema who do not respond to an increase in loop diuretic doses.</li> <li>• In patients with acute HF and SBP &gt;110 mmHg, intravenous vasodilators may be considered as initial therapy to improve symptoms and reduce congestion.</li> <li>• Inotropic agents may be considered in patients with SBP &lt;90 mmHg and evidence of hypoperfusion who do not respond to standard treatment, including fluid challenge, to improve peripheral perfusion and maintain end-organ function.</li> <li>• Inotropic agents are not recommended routinely, due to safety concerns, unless the patient has symptomatic hypotension and evidence of hypoperfusion.</li> <li>• A vasopressor, preferably norepinephrine, may be considered in patients with cardiogenic shock to increase blood pressure and vital organ perfusion.</li> <li>• Thromboembolism prophylaxis (e.g. with LMWH) is recommended in patients not already anticoagulated and with no contraindication to anticoagulation, to reduce the risk of deep venous thrombosis and pulmonary embolism.</li> <li>• Routine use of opiates is not recommended, unless in selected patients with severe/intractable pain or anxiety.</li> </ul>
<p>Eighth Joint National Committee (JNC 8): <b>2014 Evidence-based Guideline for the Management of High Blood Pressure in Adults (2014)</b><sup>28</sup></p>	<ul style="list-style-type: none"> <li>• Pharmacologic treatment should be initiated in patients ≥60 years of age to lower blood pressure at systolic blood pressure ≥150 mm Hg or diastolic blood pressure ≥90 mm Hg and to a goal systolic blood pressure &lt;150 mm Hg and goal diastolic blood pressure &lt;90 mm Hg. Adjustment of treatment is not necessary if treatment results in lower blood pressure and treatment is well tolerated and without adverse effects on health or quality of life.</li> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at diastolic blood pressure ≥90 mm Hg to a goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥150 mm Hg to a goal diastolic blood pressure &lt;140 mm Hg.</li> <li>• For patients ≥18 years of age with chronic kidney disease or diabetes, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥140 mm Hg or diastolic blood pressure ≥90 mm Hg and to a goal systolic blood pressure &lt;140 mm Hg and goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• Initial antihypertensive treatment for the general nonblack population, including those with diabetes, should include thiazide-type diuretic, calcium channel blocker (CCB), ACE inhibitor, or ARB.</li> <li>• Initial antihypertensive treatment for the general black population, including those with diabetes, should include thiazide-type diuretic or CCB.</li> <li>• For patients ≥18 years of age with chronic kidney disease regardless of race or diabetes status, initial (or add-on) treatment should include an ACE inhibitor or ARB to improve kidney outcomes.</li> <li>• The main goal of antihypertensive treatment is to attain and maintain goal blood pressure.</li> <li>• If goal blood pressure is not attained within a month of treatment, the dose of the initial drug should be increased or second drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• If goal is not achieved with two drugs, a third drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• An ACE inhibitor and ARB should not be used together.</li> <li>• Antihypertensive classes can be used if the patient is unable to achieve goal blood pressure with three agents or had a contraindication to a preferred class.</li> <li>• If blood pressure is not able to be achieved or in complicated patients, referral to a hypertension specialist may be indicated.</li> </ul>
<p>International Society of Hypertension: Global Hypertension Practice Guidelines (2020)<sup>29</sup></p>	<p><b>Lifestyle modifications</b></p> <ul style="list-style-type: none"> <li>• Lifestyle modification is the first line of antihypertensive treatment.</li> <li>• Salt reduction: Reduce salt added when preparing foods, and at the table. Avoid or limit consumption of high salt foods such as soy sauce, fast foods and processed food including breads and cereals high in salt.</li> <li>• Healthy diet: Eating a diet that is rich in whole grains, fruits, vegetables, polyunsaturated fats and dairy products and reducing food high in sugar, saturated fat and trans fats, such as the DASH diet.</li> <li>• Healthy drinks: Moderate consumption of coffee, green and black tea. Other beverages that can be beneficial include karkadé (hibiscus) tea, pomegranate juice, beetroot juice and cocoa.</li> <li>• Moderation of alcohol consumption: The recommended daily limit for alcohol consumptions is 2 standard drinks for men and 1.5 for women (10 g alcohol/standard drink). Avoid binge drinking.</li> <li>• Weight reduction: Body weight control is indicated to avoid obesity. Particularly abdominal obesity should be managed. Ethnic-specific cut-offs for BMI and waist circumference should be used. Alternatively, a waist-to-height ratio &lt;0.5 is recommended for all populations.</li> <li>• Smoking cessation: Smoking is a major risk factor for cardiovascular disease (CVD), COPD and cancer. Smoking cessation and referral to smoking cessation programs are advised.</li> <li>• Regular physical activity: Studies suggest that regular aerobic and resistance exercise may be beneficial for both the prevention and treatment of hypertension. Moderate intensity aerobic exercise (walking, jogging, cycling, yoga, or swimming) for 30 minutes on five to seven days per week Strength training also can help reduce blood pressure. Performance of resistance/strength exercises on two to three days per week.</li> <li>• Reduce stress and induce mindfulness: Stress should be reduced and mindfulness or meditation introduced into the daily routine.</li> <li>• Reduce exposure to air pollution and cold temperature: Evidence from studies support a negative effect of air pollution on blood pressure in the long-term.</li> </ul> <p><b>Pharmacological Treatment</b></p> <ul style="list-style-type: none"> <li>• Ideal characteristics of drug treatment <ul style="list-style-type: none"> <li>○ Treatments should be evidence-based in relation to morbidity/mortality prevention.</li> <li>○ Use a once-daily regimen which provides 24-hour blood pressure control.</li> <li>○ Treatment should be affordable and/or cost-effective relative to other agents.</li> <li>○ Treatments should be well-tolerated.</li> <li>○ Evidence of benefits of use of the medication in populations to which it is to be applied.</li> </ul> </li> <li>• General scheme for drug treatment <ul style="list-style-type: none"> <li>○ Lifestyle modification is the first line of antihypertensive treatment.</li> <li>○ Grade 1 hypertension (BP 140 to 159/ 90 to 99): Immediate drug treatment in high-risk patients or those with CVD, chronic kidney disease (CKD), diabetes mellitus (DM), or hypertension-mediated organ damage</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>(HMOD). Drug treatment after three to six months of lifestyle intervention if BP still not controlled in low to moderate risk patients.</p> <ul style="list-style-type: none"> <li>○ Grade 2 hypertension (BP <math>\geq</math>160/100): Immediated drug treatment in all patients.</li> <li>● Core drug-treatment strategy <ul style="list-style-type: none"> <li>○ Step 1: Dual low-dose combination (ACE inhibitor or ARB plus dihydropyridine-calcium channel blockers (DHP-CCB)); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance; consider ACE/ARB plus DHP-CCB or DHP-CCB plus thiazide-like diuretics in black patients.</li> <li>○ Step 2: Dual full-dose combination (ACE inhibitor or ARB plus DHP-CCB); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq</math>80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance.</li> <li>○ Step 3: Triple combination (ACE/ARB plus DHP-CCB plus thiazide-like diuretic).</li> <li>○ Step 4, resistant hypertension: triple combination plus spironolactone or other drug, alternatives include amiloride, doxazosin, eplerenone, clonidine, or <math>\beta</math>-blocker. Caution with spironolactone or other potassium sparing diuretics when estimated GFR <math>&lt;</math>45 mL/min/1.73m<sup>2</sup> or K<sup>+</sup> <math>&gt;</math>4.5 mmol/L.</li> <li>○ Consider <math>\beta</math>-blockers at any treatment step when there is a specific indications for their use, e.g., heart failure, angina, post-MI, atrial fibrillation, or younger women planning pregnancy or pregnant.</li> </ul> </li> </ul>
<p>Hypertension Canada: 2020 Guidelines for the Prevention, Diagnosis, Risk Assessment, and Treatment of Hypertension in Adults and Children (2020)<sup>30</sup></p>	<p><u>Indications for drug therapy for adults with hypertension without compelling indications for specific agents</u></p> <ul style="list-style-type: none"> <li>● Antihypertensive therapy should be prescribed for average diastolic blood pressure (DBP) measurements of <math>\geq</math>100 mmHg or average systolic blood pressure (SBP) measurements of <math>\geq</math>160 mmHg in patients without macrovascular target organ damage or other cardiovascular risk factors.</li> <li>● Antihypertensive therapy should be strongly considered for average DPB readings <math>\geq</math>90 mmHg or for average SBP readings <math>\geq</math>140 mmHg in the presence of macrovascular target organ damage or other independent cardiovascular risk factors.</li> <li>● For high-risk patients, aged 50 years or older, with SBP levels <math>\geq</math>130 mmHg, intensive management to target a SBP <math>&lt;</math>120 mmHg should be considered. Patient selection for intensive management is recommended and caution should be taken in certain high-risk groups.</li> </ul> <p><u>Indications for drug therapy for adults with diastolic and with or without systolic hypertension</u></p> <ul style="list-style-type: none"> <li>● Initial therapy should be with either monotherapy or single pill combination (SPC). <ul style="list-style-type: none"> <li>○ Recommended monotherapy choices are: <ul style="list-style-type: none"> <li>▪ A thiazide/thiazide-like diuretic, with longer-acting diuretics preferred;</li> <li>▪ A <math>\beta</math>-blocker (in patients <math>&lt;</math>60 years of age);</li> <li>▪ An angiotensin-converting enzyme (ACE) inhibitor (in nonblack patients);</li> <li>▪ An angiotensin receptor blocker (ARB); or</li> <li>▪ A long-acting calcium channel blocker (CCB).</li> </ul> </li> <li>○ Recommended SPC choices are those in which an ACE inhibitor is combined with a CCB, ARB with a CCB, or ACE inhibitor or ARB with a diuretic.</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>○ Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line choices. Useful choices include a thiazide/thiazide-like diuretic or CCB with either: ACE inhibitor, ARB, or <math>\beta</math>-blocker. Caution should be exercised in combining a nondihydropyridine CCB and a <math>\beta</math>-blocker. The combination of an ACE inhibitor and an ARB is not recommended.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other antihypertensive drugs may be added.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated hypertension; <math>\beta</math>-blockers are not recommended as first-line therapy for uncomplicated hypertension in patients <math>\geq 60</math> years of age; and ACE inhibitors are not recommended as first-line therapy for uncomplicated hypertension in black patients. However, these agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Indications for drug therapy for adults with isolated systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be single-agent therapy with a thiazide/thiazide-like diuretic, a long-acting dihydropyridine CCB, or an ARB. If there are adverse effects, another drug from this group should be substituted. Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line options.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other classes of drugs (such as <math>\alpha</math>-blockers, ACE inhibitors, centrally acting agents, or nondihydropyridine CCBs) may be combined or substituted.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated isolated systolic hypertension; and <math>\beta</math>-blockers are not recommended as first-line therapy for isolated systolic hypertension in patients <math>\geq 60</math> years of age. However, both agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Guidelines for hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• For most hypertensive patients with CAD, an ACE inhibitor or ARB is recommended.</li> <li>• For hypertensive patients with CAD, but without coexisting systolic heart failure, the combination of an ACE inhibitor and ARB is not recommended.</li> <li>• For high-risk hypertensive patients, when combination therapy is being used, choices should be individualized. The combination of an ACE inhibitor and a dihydropyridine CCB is preferable to an ACE inhibitor and a thiazide/thiazide-like diuretic in selected patients.</li> <li>• For patients with stable angina pectoris but without previous heart failure, myocardial infarction, or coronary artery bypass surgery, either a <math>\beta</math>-blocker or CCB can be used as initial therapy.</li> <li>• Short-acting nifedipine should not be used.</li> <li>• When decreasing SBP to target levels in patients with established CAD (especially if isolated systolic hypertension is present), be cautious when the DBP is <math>\leq 60</math> mmHg because of concerns that myocardial ischemia might be exacerbated, especially in patients with left ventricular hypertrophy (LVH).</li> </ul>

Clinical Guideline	Recommendations
	<p><b>Guidelines for patients with hypertension who have had a recent myocardial infarction</b></p> <ul style="list-style-type: none"> <li>• Initial therapy should include a <math>\beta</math>-blocker as well as an ACE inhibitor.</li> <li>• An ARB can be used if the patient is intolerant of an ACE inhibitor.</li> <li>• CCBs may be used in patients after myocardial infarction when <math>\beta</math>-blockers are contraindicated or not effective. Nondihydropyridine CCBs should not be used when there is heart failure, evidenced by pulmonary congestion on examination or radiography.</li> </ul> <p><b>Treatment of hypertension in association with heart failure</b></p> <ul style="list-style-type: none"> <li>• In patients with systolic dysfunction (ejection fraction &lt;40%), ACE inhibitors and <math>\beta</math>-blockers are recommended for initial therapy. Aldosterone antagonists (mineralocorticoid receptor antagonists) may be combined in treatment for patients with a recent cardiovascular hospitalization, acute myocardial infarction, elevated B-type natriuretic peptide or N-terminal pro-B-type natriuretic peptide level, or New York Heart Association (NYHA) Class II-IV symptoms. Careful monitoring for hyperkalemia is recommended when combining an aldosterone antagonist with ACE inhibitor or ARB treatment. Other diuretics are recommended as additional therapy if needed. Beyond considerations of BP control, doses of ACE inhibitors or ARBs should be titrated to those reported to be effective in trials unless adverse effects become manifest.</li> <li>• An ARB is recommended if ACE inhibitors are not tolerated.</li> <li>• A combination of hydralazine and isosorbide dinitrate is recommended if ACE inhibitors and ARBs are contraindicated or not tolerated.</li> <li>• For hypertensive patients whose BP is not controlled, an ARB may be combined with an ACE inhibitor and other antihypertensive drug treatment. Careful monitoring should be used if combining an ACE inhibitor and an ARB because of potential adverse effects such as hypotension, hyperkalemia, and worsening renal function. Additional therapies may also include dihydropyridine CCBs.</li> <li>• An angiotensin receptor-neprilysin inhibitor (ARNI) should be used in place of an ACE inhibitor or ARB for patients with HFrEF (&lt;40%) who remain symptomatic despite treatment with appropriate dose of guideline directed HF therapy. Eligible patients must have a serum potassium &lt;5.2 mmol/L, an eGFR <math>\leq</math>30 mL/min/1.73m<sup>2</sup> and close surveillance of serum potassium and creatinine.</li> </ul> <p><b>Treatment of hypertension in association with stroke</b></p> <ul style="list-style-type: none"> <li>• BP management in acute ischemic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> <li>• BP management after acute ischemic stroke <ul style="list-style-type: none"> <li>○ Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack.</li> <li>○ After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently &lt;140/90 mmHg.</li> <li>○ Treatment with an ACE inhibitor and thiazide/thiazide-like diuretic combination is preferred.</li> <li>○ For patients with stroke, the combination of an ACE inhibitor and ARB is not recommended.</li> </ul> </li> <li>• BP management in hemorrhagic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> </ul> <p><b>Treatment of hypertension in association with LVH</b></p> <ul style="list-style-type: none"> <li>• Hypertensive patients with LVH should be treated with antihypertensive therapy to decrease the rate of subsequent cardiovascular events.</li> <li>• The choice of initial therapy can be influenced by the presence of LVH. Initial therapy can be drug treatment using ACE inhibitors, ARBs, long-acting CCBs, or thiazide/thiazide-like diuretics. Direct arterial vasodilators such as hydralazine or</li> </ul>

Clinical Guideline	Recommendations
	<p><b>minoxidil should not be used.</b></p> <p><b>Treatment of hypertension in association with nondiabetic chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>• Individualize BP targets in patients with chronic kidney disease. Consider intensive targets (SBP &lt;120 mmHg) in appropriate patients.</li> <li>• For patients with hypertension and proteinuric chronic kidney disease (urinary protein &gt;150 mg per 24 hours or albumin to creatinine ratio &gt;30 mg/mmol), initial therapy should be an ACE inhibitor or an ARB if there is intolerance to ACE inhibitors.</li> <li>• In most cases, combination therapy with other antihypertensive agents might be needed to reach target BP levels.</li> <li>• The combination of an ACE inhibitor and ARB is not recommended for patients with nonproteinuric chronic kidney disease.</li> </ul> <p><b>Treatment of hypertension in association with renovascular disease</b></p> <ul style="list-style-type: none"> <li>• Patients with hypertension attributable to atherosclerotic renal artery stenosis should be primarily medically managed because renal angioplasty and stenting offers no benefit over optimal medical therapy alone.</li> <li>• Renal artery angioplasty and stenting for atherosclerotic hemodynamically significant renal artery stenosis could be considered for patients with uncontrolled hypertension resistant to maximally tolerated pharmacotherapy, progressive renal function loss, and acute pulmonary edema.</li> <li>• Patients with confirmed renal fibromuscular dysplasia (FMD) should be referred to a hypertension specialist.</li> <li>• Renal artery angioplasty without stenting is recommended for treatment of FMD-related renal artery stenosis. Stenting is not recommended unless needed because of a periprocedural dissection. Surgical revascularization should be considered in cases of complex lesions less amendable to angioplasty, stenosis associated with complex aneurysm, and restenosis despite two unsuccessful attempts of angioplasty.</li> </ul> <p><b>Treatment of hypertension in association with diabetes mellitus</b></p> <ul style="list-style-type: none"> <li>• Persons with diabetes mellitus should be treated to attain SBP of &lt;130 mmHg and DBP of &lt;80 mmHg.</li> <li>• For persons with cardiovascular or kidney disease, including microalbuminuria, or with cardiovascular risk factors in addition to diabetes and hypertension, an ACE inhibitor or an ARB is recommended as initial therapy.</li> <li>• For persons with diabetes and hypertension not included in other guidelines in this section, appropriate choices include (in alphabetical order): ACE inhibitors, ARBs, dihydropyridine CCBs, and thiazide/thiazide-like diuretics.</li> <li>• If target BP levels are not achieved with standard-dose monotherapy, additional antihypertensive therapy should be used. For persons in whom combination therapy with an ACE inhibitor is being considered, a dihydropyridine CCB is preferable to a thiazide/thiazide-like diuretic.</li> </ul> <p><b>Resistant hypertension</b></p> <ul style="list-style-type: none"> <li>• Resistant hypertension is defined as BP above target despite three or more BP-lowering drugs at optimal doses preferably including a diuretic (and usually a renin-angiotensin-aldosterone system blocker and a CCB).</li> <li>• Accurate office and out-of-office BP measurement is essential.</li> <li>• Other reasons for apparent resistant hypertension should be eliminated before diagnosing true resistant hypertension, including nonadherence, white coat effect, and secondary hypertension.</li> <li>• Pharmacotherapy with the additional use of spironolactone, bisoprolol, doxazosin,</li> </ul>

Clinical Guideline	Recommendations
	<p>amiloride, eplerenone, or clonidine with the baseline regimen decreases BP significantly, with the greatest BP-lowering shown with spironolactone.</p> <ul style="list-style-type: none"> <li>Patients with resistant hypertension should be referred to providers with expertise in diagnosis and management of hypertension.</li> </ul> <p><u>Hypertension and pediatrics</u></p> <ul style="list-style-type: none"> <li>BP should be measured regularly in children three years of age or older; the auscultatory method is the gold-standard at present.</li> <li>Initial therapy should be monotherapy, with an ACE inhibitor or ARB (not first-line in black children), or a long-acting dihydropyridine CCB.</li> <li>The treatment goal is systolic and diastolic office BP and/or ABPM &lt; 95th percentile or &lt;90<sup>th</sup> percentile in children with risk factors or target organ damage.</li> <li>Complex cases should be referred to an expert in pediatric hypertension.</li> </ul> <p><u>Hypertension and pregnancy</u></p> <ul style="list-style-type: none"> <li>Up to 7% of pregnancies are complicated by a hypertensive disorder of pregnancy, and approximately 5% of women will have chronic hypertension when they become pregnant.</li> <li>The prevalence of hypertension in pregnancy is expected to increase with women becoming pregnant later in their reproductive years and the increasing prevalence of cardiovascular comorbidities such as increased preconception body mass index and maternal diabetes.</li> <li>The possibility of pregnancy should be considered when managing women with hypertension who are of reproductive age.</li> <li>Preconception counselling should be offered to all women with hypertension who are considering pregnancy.</li> <li>ACE inhibitor and ARB therapy should be avoided before conception and during pregnancy unless there is a compelling indication for their use (i.e., proteinuric kidney disease).</li> <li>Hypertension during pregnancy can increase the risk of adverse maternal and fetal outcomes, including an increased risk of preeclampsia, placental abruption, prematurity, small for gestational age infants, stillbirth, and maternal renal and retinal injury, thus generally requires involvement of an interdisciplinary team including obstetrical care providers.</li> <li>Antihypertensive therapy is recommended for average SBP measurements of <math>\geq 140</math> mmHg or DBP measurements of <math>\geq 90</math> mmHg in pregnant women with chronic hypertension, gestational hypertension, or preeclampsia. Initial antihypertensive therapy should be monotherapy from the following first-line drugs: oral labetalol, oral methyldopa, long-acting oral nifedipine, or other oral <math>\beta</math>-blockers (acebutolol, metoprolol, pindolol, and propranolol). Other antihypertensive drugs can be considered as second-line drugs including: clonidine, hydralazine, and thiazide diuretics.</li> <li>Women with severe hypertension with SBP <math>\geq 160</math> mmHg or DBP <math>\geq 110</math> mmHg in pregnancy or postpartum require urgent antihypertensive therapy because it is considered an obstetrical emergency.</li> <li>Antihypertensive drugs used in breastfeeding women include: labetalol, methyldopa, long-acting nifedipine, enalapril, or captopril.</li> </ul>
<p>European Society of Hypertension/ European Society of Cardiology: <b>2018 Guidelines for the management of arterial hypertension (2018)</b><sup>31</sup></p>	<p><u>Treatment strategies and choice of antihypertensive drugs</u></p> <ul style="list-style-type: none"> <li>Diuretics (including thiazides, chlorthalidone, and indapamide), <math>\beta</math>-blockers, calcium channel blocker (CCB), angiotensin-converting enzyme (ACE) inhibitors, and angiotensin receptor blockers (ARBs) are all suitable for the initiation and maintenance of antihypertensive treatment, either as monotherapy or in some combinations.</li> <li>Some agents should be considered as the preferential choice in specific conditions</li> </ul>

Clinical Guideline	Recommendations
	<p>because used in trials in those conditions or because of greater effectiveness in specific types of organ damage. Preferred combinations should comprise a renin-angiotensin system (RAS) blocker (either an ACE inhibitor or an ARB) with a CCB or diuretic.</p> <ul style="list-style-type: none"> <li>• It is recommended that beta-blockers are combined with any of the other major drug classes when there are specific clinical situations, e.g. angina, post-myocardial infarction, heart failure, or heart rate control.</li> <li>• Initiation of antihypertensive therapy with a two-drug combination may be considered in patients with markedly high baseline blood pressure (BP) or at high cardiovascular (CV) risk.</li> <li>• The combination of two antagonists of the RAS is not recommended and should be discouraged.</li> <li>• Other drug combinations should be considered and probably are beneficial in proportion to the extent of BP reduction. However, combinations that have been successfully used in trials may be preferable.</li> <li>• Combinations of two antihypertensive drugs at fixed doses in a single tablet may be recommended and favored, because reducing the number of daily pills improves adherence, which is low in patients with hypertension. Exceptions are frail older patients and those at low risk and with grade one hypertension (particularly if systolic BP is &lt;150 mmHg).</li> <li>• It is recommended that if BP is not controlled with a three-drug combination, treatment should be increased by the addition of spironolactone or, if not tolerated, other diuretics such as amiloride or higher doses of other diuretics, a beta-blocker, or an alpha-blocker.</li> </ul> <p><u>Treatment strategies in white-coat and masked hypertension</u></p> <ul style="list-style-type: none"> <li>• In white-coat hypertensives without additional risk factors, therapeutic intervention may be limited to lifestyle changes only, but this decision should be accompanied by close follow-up.</li> <li>• In white-coat hypertensives with a higher CV risk or hypertension-mediated organ damage, drug treatment may be considered in addition to lifestyle changes.</li> <li>• In masked hypertension, both lifestyle measures and antihypertensive drug treatment should be considered, because this type of hypertension has been consistently found to have a CV risk very close to that of in- and out-of-office hypertension.</li> <li>• Antihypertensive drug up-titration should be considered in treated patients whose out-of-office BP is not controlled (i.e., masked uncontrolled hypertension), because of the high CV risk of these patients.</li> </ul> <p><u>Antihypertensive treatment strategies in the elderly</u></p> <ul style="list-style-type: none"> <li>• It is recommended that older patients (<math>\geq 65</math> years) are treated with the same recommendations in non-older patient population. In very old patients (<math>\geq 80</math> years), it may be appropriate to initiate treatment with monotherapy.</li> <li>• In all older patients, when combination therapy is used, it is recommended that this is initiated at the lowest available doses. In all older patients, and especially very old or frail patients, the possible occurrence of postural BP should be closely monitored and symptoms of possible hypotensive episodes checked by ambulatory blood pressure monitoring.</li> <li>• Unless required for concomitant diseases, loop diuretics and alpha-blockers should be avoided because of their association with injurious falls.</li> <li>• Renal function should be frequently assessed to detect possible increases in serum creatinine and reductions in estimated glomerular filtration rate (eGFR) as a result of BP-related reductions in renal perfusion.</li> <li>• When treated, BP should be lowered to a systolic value of 130 to 139 mmHg and a diastolic value of &lt;80 mmHg if tolerated. Treated values of &lt;130 mmHg should</li> </ul>

Clinical Guideline	Recommendations
	<p>be avoided.</p> <p><u>Treatment strategies in hypertensive women</u></p> <ul style="list-style-type: none"> <li>• Hormone therapy and selective estrogen receptor modulators are not recommended and should not be used for primary or secondary prevention of CVD.</li> <li>• In women with gestational hypertension, pre-existing hypertension superimposed by gestational hypertension, or with hypertension and subclinical organ damage or symptoms, initiation of drug treatments is recommended when SBP is <math>\geq 140</math> mmHg or DBP <math>\geq 90</math> mmHg. In all other cases, initiation of drug treatment is recommended when SBP is <math>\geq 150</math> mmHg or DBP is <math>\geq 95</math> mmHg.</li> <li>• Methyldopa, labetalol, and CCBs are recommended as the drugs of choice for the treatment of hypertension in pregnancy.</li> <li>• ACE inhibitors, ARBs, or direct renin inhibitors are not recommended during pregnancy.</li> <li>• SBP <math>\geq 170</math> mmHg or DBP <math>\geq 110</math> mmHg in a pregnant woman is an emergency, and admission to hospital is recommended.</li> <li>• In severe hypertension, drug treatment with intravenous (IV) labetalol, oral methyldopa, or nifedipine is recommended.</li> <li>• The recommended treatment for hypertensive crisis is IV labetalol or nicardipine and magnesium.</li> <li>• In pre-eclampsia associated with pulmonary edema, nitroglycerin given as an IV infusion is recommended.</li> <li>• In women with gestational hypertension or mild-pre-eclampsia, delivery is recommended at 37 weeks.</li> <li>• It is recommended to expedite delivery in pre-eclampsia with adverse conditions, such as visual disturbances or hemostatic disorders</li> <li>• In women at high risk of pre-eclampsia, provided they are at low risk of gastrointestinal hemorrhage, treatment with low dose aspirin from 12 weeks until delivery may be considered.</li> <li>• Methyldopa, labetalol, and nifedipine should be considered preferential antihypertensive drugs in pregnancy. Intravenous labetalol or infusion of nitroprusside should be considered in case of emergency (pre-eclampsia).</li> </ul> <p><u>Treatment strategies in patients with diabetes</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive drug treatment is recommended for people with diabetes when office BP is <math>\geq 140/90</math> mmHg.</li> <li>• A SBP goal <math>&lt; 130</math> mmHg is recommended in patients with diabetes and <math>&lt; 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg.</li> <li>• In older people, the target SBP range is 130 to 139 mmHg.</li> <li>• The DBP target in patients with diabetes is recommended to be <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• It is recommended to initiate treatment with a combination of a RAS blocker with a CCB or thiazide/thiazide-like diuretic.</li> <li>• It is recommended that individual drug choice takes comorbidities into account.</li> <li>• Simultaneous administration of two blockers of the RAS is not recommended and should be avoided in patients with diabetes.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with nephropathy</u></p> <ul style="list-style-type: none"> <li>• In patients with diabetic and non-diabetic CKD, it is recommended that an office BP of <math>\geq 140/90</math> mmHg be treated with lifestyle advice and BP-lowering medication.</li> <li>• In patients with diabetic or non-diabetic CKD, it is recommended to lower SBP to a range of 130 to 139 mmHg. And individualized treatments should be considered</li> </ul>

Clinical Guideline	Recommendations
	<p>according to its tolerability and impact on renal function and electrolytes.</p> <ul style="list-style-type: none"> <li>• A combination of a RAS blocker with a CCB or a diuretic is recommended as initial therapy.</li> <li>• RAS blockers are more effective in reducing albuminuria than other antihypertensive agents, and are indicated in hypertensive patients in the presence of microalbuminuria or overt proteinuria.</li> <li>• Combination of two RAS blockers, though potentially more effective in reducing proteinuria, is not recommended.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with cerebrovascular disease</u></p> <ul style="list-style-type: none"> <li>• In patients with acute intracerebral hemorrhage, immediate BP lowering is not recommended for patients with SBP &lt;220 mmHg. In patients with SBP <math>\geq</math>220 mmHg, care acute BP lowering with IV therapy to &lt;180 mmHg should be considered.</li> <li>• In acute ischemic stroke, routine BP lowering with antihypertensive therapy is not recommended with the exceptions with the exceptions: in patients with acute ischemic stroke who are eligible for IV thrombolysis, BP should be carefully lowered and maintained at &lt;180/105 mmHg for at least the first 24 hours after thrombolysis; In patients with markedly elevated BP who do not receive fibrinolysis, drug therapy may be considered, based on clinical judgement, to reduce BP by 15% during the first 24 hours after the stroke onset.</li> <li>• In hypertensive patients with an acute cerebrovascular event, antihypertensive treatment is recommended immediately for transient ischemic attack (TIA) and after several days in ischemic stroke.</li> <li>• In all hypertensive patients with ischemic stroke or TIA, an SBP target range of 120 to 130 mmHg should be considered.</li> <li>• The recommended antihypertensive drug treatment strategy for stroke prevention is a RAS blocker plus a CCB or a thiazide-like diuretic.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with heart failure (HF) or left ventricular hypertrophy (LVH)</u></p> <ul style="list-style-type: none"> <li>• In hypertensive patients with heart failure (with reduced or preserved ejection fraction), BP-lowering treatment should be considered if <math>\geq</math>140/90 mmHg.</li> <li>• In patients with HFrEF, it is recommended that BP-lowering treatment comprises an ACE inhibitor or ARB, and a beta-blocker and a diuretic and/or mineralocorticoid receptor antagonist (MRA) if required.</li> <li>• Dihydropyridine CCBs may be added if BP control is not achieved.</li> <li>• In patients with HFpEF, BP treatment threshold and target values should be the same as for HFrEF).</li> <li>• Because no specific drug has proven its superiority, all major agents can be used.</li> <li>• In all patients with LVH, it is recommended to treat with a RAS blocker or in combination with a CCB or diuretic and SBP should be lowered to a range of 120 to 130 mmHg.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• In patients with CAD receiving BP-lowering drugs, it is recommended to target SBP to <math>\leq</math>130 mmHg if tolerated, but not &lt;120 mmHg. In older patients, the target is an SBP range of 130 to 140 mmHg. The target DBP is &lt;80 mmHg, but not &lt;70 mmHg.</li> <li>• In hypertensive patients with a history of myocardial infarction, beta-blockers and RAS blockers are recommended as part of treatment.</li> <li>• In patients with asymptomatic angina, beta-blockers and/or CCBs are recommended.</li> </ul>

Clinical Guideline	Recommendations
<p>National Institute for Health and Clinical Excellence: <b>Hypertension in adults: diagnosis and management (2019)</b><sup>32</sup></p>	<p><u>Choosing antihypertensive drug treatment (for people with or without type II diabetes)</u></p> <ul style="list-style-type: none"> <li>• Where possible, recommend treatment with drugs taken only once a day.</li> <li>• Prescribe non-proprietary drugs where these are appropriate and minimize cost.</li> <li>• Offer people with isolated systolic hypertension (systolic blood pressure <math>\geq 160</math> mmHg) the same treatment as people with both raised systolic and diastolic blood pressure.</li> <li>• Offer antihypertensive drug treatment to women of child-bearing potential with diagnosed hypertension in line with recommendations in this guideline. For women considering pregnancy or who are pregnant or breastfeeding, manage hypertension in line with the recommendations on Management of pregnancy with chronic hypertension and Breastfeeding in 'Hypertension in pregnancy'.</li> <li>• When choosing antihypertensive drug treatment for adults of black African or African-Caribbean family origin, consider an angiotensin II receptor blocker, in preference to an angiotensin-converting enzyme inhibitor.</li> </ul> <p><u>Step one treatment</u></p> <ul style="list-style-type: none"> <li>• Patients &lt;55 years of age should be offered a step one antihypertensive with an angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB).</li> <li>• Offer an ACE inhibitor or an ARB to adults starting step 1 antihypertensive treatment who have type II diabetes and are of any age or family origin or those aged &lt;55 years but not of black African or African-Caribbean family origin.</li> <li>• If an ACE inhibitor is not tolerated, offer an ARB.</li> <li>• Do not combine an ACE inhibitor with an ARB for the treatment of hypertension.</li> <li>• Offer a calcium channel blocker (CCB) to adults starting step 1 antihypertensive treatment who are &gt;55 years of age and do not have diabetes and are of black African or African-Caribbean family origin and do not have type II diabetes and of any age.</li> <li>• If a CCB is not suitable, for example because of edema or intolerance, or if there is evidence of heart failure or a high risk of heart failure, offer a thiazide-like diuretic.</li> <li>• If diuretic treatment is to be initiated or changed, offer a thiazide-like diuretic, such as indapamide in preference to a conventional thiazide diuretic such as bendroflumethiazide or hydrochlorothiazide.</li> <li>• For adults with hypertension who are already receiving treatment with bendroflumethiazide or hydrochlorothiazide, who have stable, well-controlled blood pressure, continue with their treatment.</li> </ul> <p><u>Step two treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering next step treatment for hypertension discuss with the person if they are taking their medicine as prescribed and support adherence in line with NICE's guideline on "Medicines adherence: involving patients decisions about prescribed medicines and supporting adherence".</li> <li>• If hypertension is not controlled with a step one treatment of an ACE inhibitor or ARB, offer choice of one of the following drugs in addition to the step one treatment: a CCB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults taking step one treatment of a CCB, offer the choice of one of the following drugs in addition to the step one treatment: an ACE inhibitor or an ARB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults of black African or African-Caribbean family origin who do not have type 2 diabetes taking step one treatment, consider an ARB, in preference to an ACE inhibitor, in addition to step one treatment.</li> </ul> <p><u>Step three treatment</u></p>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Before considering step three treatment, review the person’s medications to ensure they are being taken at the optimal doses and discuss adherence (see recommendation under step two).</li> <li>• If hypertension is not controlled in adults taking step two treatment, offer a combination of an ACE inhibitor or ARB and a CCB and a thiazide-like diuretic.</li> </ul> <p><u>Step four treatment</u></p> <ul style="list-style-type: none"> <li>• If hypertension is not controlled in adults taking the optimal tolerated doses of an ACE inhibitor or an ARB plus a CCB and a thiazide-like diuretic, regard them as having resistant hypertension.</li> <li>• Before considering further treatment for a person with resistant hypertension, confirm elevated clinic blood pressure measurements using ambulatory or home blood pressure recordings, assess for postural hypotension, and discuss adherence.</li> <li>• For people with confirmed resistant hypertension, consider adding a fourth antihypertensive drug as step four treatment or seeking specialist advice.</li> <li>• Consider further diuretic therapy with low-dose spironolactone for adults with resistant hypertension starting step four treatment who have a blood potassium level of 4.5 mmol/l or less. Use particular caution in people with a reduced estimated glomerular filtration rate because they have an increased risk of hyperkalemia.</li> <li>• When using further diuretic therapy for step four treatment of resistant hypertension, monitor blood sodium and potassium and renal function within one month of starting treatment and repeat as needed thereafter.</li> <li>• Consider an alpha-blocker or beta-blocker for adults with resistant hypertension starting step four treatment who have a blood potassium level of more than 4.5 mmol/l.</li> <li>• If blood pressure remains uncontrolled in people with resistant hypertension taking the optimal tolerated doses of four drugs, seek specialist advice.</li> </ul>
<p>International Society on Hypertension in Blacks: <b>Management of High Blood Pressure in Blacks (2010)</b><sup>33</sup></p>	<ul style="list-style-type: none"> <li>• To attain and maintain blood pressure (BP) below target levels, multiple antihypertensive drugs will be required in most hypertensive blacks.</li> <li>• Use of two-drug combination therapy when SBP is &gt;15 mm Hg and/or DBP is &gt;10 mm Hg above goal levels is increasingly recommended as first-line therapy.</li> <li>• Two-drug regimens have generally contained a thiazide-type diuretic; however, the combination of a calcium channel blocker (CCB) with either an ACE inhibitor or an ARB has been shown equally efficacious in BP lowering but with demonstrated superiority (CCB+ACE) for hard clinical outcomes compared with the same ACE inhibitor plus a thiazide-type diuretic.</li> <li>• In secondary prevention patients, the combination therapy should include a drug(s) with the appropriate compelling indications.</li> <li>• Certain classes of antihypertensive medications, specifically diuretics and CCBs, lower BP on average more than <math>\beta</math>-blockers and renin-angiotensin system (RAS) blockers in black patients when used as monotherapies.</li> <li>• In the absence of compelling indications, when BP is near goal levels, monotherapy with a diuretic or a CCB is preferred.</li> <li>• Lifestyle modifications should be initiated in all patients with hypertension, whether or not pharmacotherapy is planned.</li> <li>• ACE inhibitors or ARBs are recommended as alternative monotherapy options in the treatment of hypertension in blacks. The rationale for their lower tier monotherapy recommendation is because they have consistently achieved lesser average reductions in BP relative to that observed with monotherapy using either a diuretic or CCB.</li> </ul>
<p><b>Kidney Disease</b> <b>Improving Clinical</b></p>	<p><u>Blood pressure measurement</u></p> <ul style="list-style-type: none"> <li>• The Work Group recommends standardized office blood pressure (BP)</li> </ul>

Clinical Guideline	Recommendations
<p>Outcomes Group: <b>KDIGO Clinical Practice Guideline for the Management of Blood Pressure in Chronic Kidney Disease (2021)</b><sup>34</sup></p>	<p>measurement in preference to routine office BP measurements for the management of high BP in adults.</p> <ul style="list-style-type: none"> <li>The Work Group suggests that out-of-office BP measurements with ambulatory BP monitoring (ABPM) or home BP monitoring (HBPM) be used to complement standardized office BP readings for the management of high BP.</li> </ul> <p><u>Lifestyle interventions for lowering BP in patients with chronic kidney disease (CKD) not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests targeting a sodium intake &lt;2 grams of sodium per day (or &lt;90 mmol of sodium per day, or &lt;5 grams of sodium chloride per day) in patients with high BP and CKD.</li> <li>The Work Group suggests that patients with high BP and CKD be advised to undertake moderate-intensity physical activity for a cumulative duration of at least 150 minutes per week, or to a level compatible with their cardiovascular and physical tolerance.</li> </ul> <p><u>BP management in patients with CKD, with or without diabetes, not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests that adults with high BP and CKD be treated with a target systolic BP (SBP) of &lt;120 mmHg, when tolerated, using standardized office BP measurement.</li> <li>The Work Group recommends starting renin-angiotensin-system inhibitors (RASi) (angiotensin-converting enzyme inhibitor [ACEi] or angiotensin II receptor blocker [ARB]) for people with high BP, CKD, and severely increased albuminuria without diabetes.</li> <li>The Work Group suggests starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately increased albuminuria without diabetes.</li> <li>The Work Group recommends starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately-to-severely increased albuminuria with diabetes.</li> <li>The Work Group recommends avoiding any combination of ACEi, ARB, and direct renin inhibitor (DRI) therapy in patients with CKD, with or without diabetes.</li> </ul> <p><u>BP management in kidney transplant recipients</u></p> <ul style="list-style-type: none"> <li>Treat adult kidney transplant recipients with high BP to a target BP of &lt;130 mmHg systolic and &lt;80 mmHg diastolic using standardized office BP measurement.</li> <li>The Work Group recommends that a dihydropyridine calcium channel blocker (CCB) or an ARB be used as the first-line antihypertensive agent in adult kidney transplant recipients.</li> </ul> <p><u>BP management in children with CKD</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests that in children with CKD, 24-hour mean arterial pressure by ABPM should be lowered to &lt;50<sup>th</sup> percentile for age, sex, and height.</li> </ul>
<p>American Diabetes Association: <b>Standards of Medical Care in Diabetes (2022)</b><sup>35</sup></p>	<p><u>Hypertension/blood pressure control</u></p> <ul style="list-style-type: none"> <li>Blood pressure should be measured at every routine visit. When possible, patients found to have elevated blood pressure (<math>\geq 140/90</math>) should have blood pressure confirmed using multiple readings, including measurements on a separate day, to diagnose hypertension. Patients with blood pressure <math>\geq 180/110</math> and cardiovascular disease could be diagnosed with hypertension at a single visit.</li> <li>All hypertensive patients with diabetes should monitor their blood pressure at home.</li> <li>For patients with diabetes and hypertension, with diabetes and hypertension, blood pressure targets should be individualized through a shared decision-making process that addresses cardiovascular risk, potential adverse effects of antihypertensive medications, and patient preferences.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• For individuals with diabetes and hypertension at higher cardiovascular risk (existing atherosclerotic cardiovascular disease [ASCVD] or 10-year ASCVD risk <math>\geq 15\%</math>), a blood pressure target of <math>&lt;130/80</math> mmHg may be appropriate, if it can be safely attained.</li> <li>• For individuals with diabetes and hypertension at lower risk for cardiovascular disease (10-year atherosclerotic cardiovascular disease risk <math>&lt;15\%</math>), treat to blood pressure target of <math>&lt;140/90</math>.</li> <li>• In pregnant patients with diabetes and preexisting hypertension, a blood pressure target of 110 to 135/85 is suggested in the interest of reducing the risk for accelerated maternal hypertension and minimizing impaired fetal growth.</li> <li>• For patients with blood pressure <math>&gt;120/80</math>, lifestyle intervention consists of weight loss when indicated, a Dietary Approaches to Stop Hypertension (DASH)-style eating pattern including reducing sodium and increasing potassium intake, moderation of alcohol intake, and increased physical activity.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq 140/90</math> mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of pharmacologic therapy to achieve blood pressure goals.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq 160/100</math> mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of two drugs or a single pill combination of drugs demonstrated to reduce cardiovascular events in patients with diabetes.</li> <li>• Treatment for hypertension should include drug classes demonstrated to reduce cardiovascular events in patients with diabetes (ACE inhibitors, angiotensin receptor blockers, thiazide-like diuretics, or dihydropyridine calcium channel blockers). ACE inhibitors or angiotensin receptor blockers are recommended first-line therapy for hypertension in people with diabetes and coronary artery disease.</li> <li>• Multiple-drug therapy is generally required to achieve blood pressure targets (but not a combination of ACE inhibitors and angiotensin receptor blockers).</li> <li>• An ACE inhibitor or angiotensin receptor blocker, at the maximum tolerated dose indicated for blood pressure treatment, is the recommended first-line treatment for hypertension in patients with diabetes and urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine or 30 to 299 mg/g creatinine. If one class is not tolerated, the other should be substituted.</li> <li>• For patients treated with an ACE inhibitor, angiotensin receptor blocker, or diuretic, serum creatinine/estimated glomerular filtration rate and serum potassium levels should be monitored at least annually.</li> <li>• Patients with hypertension who are not meeting blood pressure targets on three classes of antihypertensive medications (including a diuretic) should be considered for mineralocorticoid receptor antagonist therapy.</li> </ul> <p><b>Chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>• At least once a year, assess urinary albumin (e.g., spot urinary albumin-to-creatinine ratio) and estimated glomerular filtration rate in patients with type 1 diabetes with duration of five or more years and in all patients with type 2 diabetes.</li> <li>• Patients with diabetes and urinary albumin <math>\geq 300</math> mg/g creatinine and/ or an estimated glomerular filtration rate 30 to 60 mL/min/1.73 m<sup>2</sup> should be monitored twice annually to guide therapy.</li> <li>• Optimize glucose control to reduce the risk or slow the progression of chronic kidney disease (CKD).</li> <li>• For patients with type 2 diabetes and diabetic kidney disease, use of a sodium-glucose cotransporter 2 inhibitor in patients with an estimated glomerular filtration rate <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> and urinary albumin <math>\geq 300</math> mg/g creatinine is recommended to reduce CKD progression and cardiovascular events.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In patients with type 2 diabetes and CKD, consider use of sodium–glucose cotransporter 2 inhibitors additionally for cardiovascular risk reduction when estimated glomerular filtration rate and urinary albumin creatinine are <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> or <math>\geq 300</math> mg/g, respectively.</li> <li>• In patients with CKD who are at increased risk for cardiovascular events or CKD progression and are unable to use a sodium–glucose cotransporter 2 inhibitor, a nonsteroidal mineralocorticoid receptor antagonist (finerenone) is recommended to reduce CKD progression and cardiovascular events.</li> <li>• Optimize blood pressure control and reduce blood pressure variability to reduce the risk or slow the progression of CKD.</li> <li>• Do not discontinue renin-angiotensin system blockade for minor increases in serum creatinine (<math>\leq 30\%</math>) in the absence of volume depletion.</li> <li>• For people with nondialysis-dependent stage 3 or higher CKD, dietary protein intake should be a maximum of 0.8 g/kg body weight per day (the recommended daily allowance). For patients on dialysis, higher levels of dietary protein intake should be considered, since malnutrition is a major problem in some dialysis patients.</li> <li>• In nonpregnant patients with diabetes and hypertension, either an ACE inhibitor or an angiotensin receptor blocker is recommended for those with modestly elevated urinary albumin–to–creatinine ratio (30 to 299 mg/g creatinine) and is strongly recommended for those with urinary albumin–to–creatinine ratio <math>\geq 300</math> mg/g creatinine and/or estimated glomerular filtration rate <math>&lt; 60</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Periodically monitor serum creatinine and potassium levels for the development of increased creatinine or changes in potassium when ACE inhibitors, angiotensin receptor blockers, or diuretics are used.</li> <li>• An ACE inhibitor or an angiotensin receptor blocker is not recommended for the primary prevention of CKD in patients with diabetes who have normal blood pressure, normal urinary albumin–to–creatinine ratio (<math>&lt; 30</math> mg/g creatinine), and normal estimated glomerular filtration rate.</li> <li>• Patients should be referred for evaluation by a nephrologist if they have an estimated glomerular filtration rate <math>&lt; 30</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Promptly refer to a nephrologist for uncertainty about the etiology of kidney disease, difficult management issues, and rapidly progressing kidney disease.</li> </ul>
<p>American College of Cardiology/American Heart Association Task Force: <b>Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults (2017)</b><sup>36</sup></p>	<p><u>Initiation of Blood Pressure (BP) Treatment for Overall Cardiovascular Disease (CVD) Risk</u></p> <ul style="list-style-type: none"> <li>• Use of BP-lowering medications is recommended for secondary prevention of recurrent CVD events in patients with clinical CVD and an average systolic blood pressure (SBP) <math>\geq 130</math> mmHg or an average diastolic blood pressure (DBP) of <math>\geq 80</math> mmHg and for primary prevention in adults with an estimated 10-year atherosclerotic cardiovascular disease (ASCVD) risk of <math>\geq 10\%</math> and an average SBP of <math>\geq 130</math> mmHg or an average <math>\geq 80</math> mmHg.</li> <li>• Use of BP-lowering medication is recommended for primary prevention of CVD in adults with no history of CVD and with an estimated 10-year ASCVD risk <math>&lt; 10\%</math> and an SBP of <math>\geq 140</math> mmHg or a DBP of <math>\geq 90</math> mmHg.</li> <li>• Simultaneous use of an angiotensin converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), and/or renin inhibitor is potentially harmful and is not recommended to treat adults with hypertension.</li> <li>• For adults with confirmed hypertension and known CVD or 10-year ASCVD risk of <math>\geq 10\%</math>, a BP target <math>&lt; 130/80</math> mmHg is recommended. For adults with confirmed hypertension without additional markers of increased CVD risk, a BP target <math>&lt; 130/80</math> mmHg may be reasonable.</li> <li>• For initiation of antihypertensive drug therapy, first-line agents include thiazide diuretics, calcium channel blockers (CCBs), and ACE inhibitors or ARBs.</li> <li>• Initiation of antihypertensive drug therapy with two first-line agents of different</li> </ul>

Clinical Guideline	Recommendations
	<p>classes, either as separate agents or in a fixed-dose combination, is recommended in adults with stage 2 hypertension and an average BP &gt;20/10 mmHg above their BP target.</p> <ul style="list-style-type: none"> <li>Initiation of antihypertensive drug therapy with a single antihypertensive drug is reasonable in adults with stage 1 hypertension and BP goal &lt;130/80 mmHg with dosage titration and sequential addition of other agents to achieve the BP target.</li> </ul> <p><u>Stable Ischemic Heart Disease (SIHD)</u></p> <ul style="list-style-type: none"> <li>In adults with SIHD and hypertension, a BP target &lt;130/80 is recommended.</li> <li>Adults with SIHD and hypertension (BP <math>\geq</math>130/80 mmHg) should be treated with medications [e.g., guideline-directed medical therapy (GDMT) beta-blockers, ACE inhibitors, or ARBs] for compelling indications [e.g., previous myocardial infarction (MI), stable angina] as first-line therapy, with the addition of other drugs (e.g., dihydropyridine CCBs, thiazide diuretics, and/or mineralocorticoid receptor antagonists) as needed to further control hypertension.</li> <li>In adults with SIHD with angina and persistent uncontrolled hypertension, the addition of dihydropyridine CCBs to GDMT beta-blockers is recommended.</li> <li>In adults who have had a MI or acute coronary syndrome, it is reasonable to continue GDMT beta-blockers beyond three years as long-term therapy for hypertension.</li> <li>Beta-blockers and/or CCBs might be considered to control hypertension in patients with coronary artery disease (CAD) had an MI more than three years ago and have angina.</li> </ul> <p><u>Heart Failure</u></p> <ul style="list-style-type: none"> <li>In adults with increased risk of HF, the optimal BP in those with hypertension should be &lt;130 mmHg.</li> <li>Adults with HFrEF and hypertension should be prescribed GDMT titrated to attain a BP &lt;130/80 mmHg.</li> <li>Non-dihydropyridine CCBs are not recommended in the treatment of hypertension in adults with HFrEF.</li> <li>In adults with HFpEF who present with symptoms of volume overload, diuretics should be prescribed to control hypertension.</li> <li>Adults with HFpEF and persistent hypertension after management of volume overload should be prescribed ACE inhibitors or ARBs and beta-blockers titrated to attain SBP &lt;130 mmHg.</li> </ul> <p><u>CKD</u></p> <ul style="list-style-type: none"> <li>Adults with hypertension and CKD should be treated to a BP goal &lt;130/80 mmHg.</li> <li>In adults with hypertension and CKD [stage 3 or higher or stage 1 or 2 with albuminuria (<math>\geq</math>300 mg/d, or <math>\geq</math>300 mg/g albumin-to-creatinine ratio or the equivalent in the first morning void)], treatment with an ACE inhibitor is reasonable to slow kidney disease progression. Treatment with an ARB may be reasonable if an ACE inhibitor is not tolerated.</li> <li>After kidney transplantation, it is reasonable to treat patients with hypertension to a BP goal &lt;130/80 mmHg and with a CCB on the basis of improved glomerular filtration rate (GFR) and kidney survival.</li> </ul> <p><u>Cerebrovascular Disease</u></p> <ul style="list-style-type: none"> <li>In adults with intracerebral hemorrhage (ICH) who present with SBP &gt;220 mmHg, it is reasonable to use continuous intravenous (IV) drug infusion and close BP monitoring to lower levels. Immediate lowering of SBP to &lt;140 mmHg in adults with spontaneous ICH who present within six hours of the acute event and have an SBP between 150 mmHg and 220 mmHg is not of benefit to reduce death or severe disability and can be potentially harmful.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Adults with acute ischemic stroke and elevated BP who are eligible for treatment with IV tissue plasminogen activator (tPA) should have their BP slowly lowered to &lt;185/110 mmHg before thrombolytic therapy is initiated.</li> <li>• In adults with an acute ischemic stroke, BP should be &lt;185/110 mmHg before administration of IV tPA and should be maintained below 180/105 mmHg for at least the first 24 hours after initiation drug therapy.</li> <li>• Starting or restarting antihypertensive therapy during hospitalization in patients with BP &gt;140/90 mmHg who are neurologically stable is safe and reasonable to improve long-term BP control, unless contraindicated.</li> <li>• In patient with BP <math>\geq</math>220/120 mmHg who did not receive IV alteplase or endovascular treatment and have no comorbid conditions requiring acute antihypertensive treatment, the benefit of initiating or reinitiating treatment of hypertension within the first 48 to 72 hours is uncertain. It might be reasonable to lower BP by 15% during the first 24 hours after onset of stroke. In patients with BP &lt;220/120 mmHg with the same conditions, initiating or reinitiating treatment of hypertension within the first 48 to 72 hours after an acute ischemic stroke is not effective to prevent death or dependency.</li> <li>• Adults with previously treated stroke or transient ischemic attack should be restarted on antihypertensive treatment after the first few days of the index event to reduce the risk of recurrent stroke and other vascular events. Treatment with a thiazide diuretic, ACE inhibitor, or ARB, or combination treatment consisting of a thiazide diuretic plus ACE inhibitor, is useful.</li> <li>• Adults not previously treated for hypertension who experienced a stroke or transient ischemic attack and have an established BP <math>\geq</math>140/90 mmHg should be prescribed antihypertensive treatment a few days after the index event to reduce the risk of recurrent stroke and other vascular event.</li> <li>• For adults who experience a stroke or transient ischemic attack, selection of specific drugs should be individualized on the basis of patient comorbidities and agent pharmacological class.</li> <li>• For adults who experience a stroke or transient ischemic attack, a BP goal &lt;130/80 mmHg may be reasonable.</li> <li>• For adults with a lacunar stroke, a target SBP goal &lt;130 mmHg may be reasonable.</li> <li>• In adults previously untreated for hypertension who experience an ischemic stroke or transient ischemic attack and have an SBP &lt;140 mmHg and a DBP &lt;90 mmHg, the usefulness of initiating antihypertensive treatment is not well established.</li> </ul> <p><u>Peripheral Artery Disease (PAD)</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and PAD should be treated similarly to patients with hypertension without PAD.</li> </ul> <p><u>Diabetes Mellitus (DM)</u></p> <ul style="list-style-type: none"> <li>• In adults with DM and hypertension, antihypertensive drug treatment should be initiated at a BP of <math>\geq</math>130/80 mmHg with a treatment goal &lt;130/80 mmHg.</li> <li>• In adults with DM and hypertension, all first-line classes of antihypertensive agents (i.e., diuretics, ACE inhibitors, ARBs, and CCBs) are useful and effective.</li> <li>• In adults with DM and hypertension, ACE inhibitors or ARBs may be considered in the presence of albuminuria.</li> </ul> <p><u>Atrial Fibrillation, Valvular Heart Disease, and Aortic disease</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension can be useful for prevention of recurrence of AF.</li> <li>• In adults with asymptomatic aortic stenosis, hypertension should be treated with pharmacotherapy, starting at a low dose and gradually titrating upward as needed.</li> <li>• In patients with chronic aortic insufficiency, treatment of systolic hypertension</li> </ul>

Clinical Guideline	Recommendations
	<p>with agents that do not slow the heart rate (i.e., avoid beta-blockers) is reasonable.</p> <ul style="list-style-type: none"> <li>• Beta-blockers are recommended as the preferred antihypertensive agents in patients with hypertension and thoracic aortic disease.</li> </ul> <p><u>Racial and Ethnic Differences in Treatment</u></p> <ul style="list-style-type: none"> <li>• In black adults with hypertension but without HF or CKD, including those with DM, initial antihypertensive treatment should include a thiazide-type diuretic or CCB. Two or more antihypertensive medications are recommended to achieve a BP target &lt;130/80 mmHg in most adults with hypertension, especially in black adults with hypertension.</li> </ul> <p><u>Pregnancy</u></p> <ul style="list-style-type: none"> <li>• Women with hypertension who become pregnant, or are planning to become pregnant, should be transitioned to methyldopa, nifedipine, and/or labetalol during pregnancy.</li> <li>• Women with hypertension who become pregnant should not be treated with ACE inhibitors, ARBs, or direct renin inhibitors.</li> </ul> <p><u>Older Persons</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension with an SBP treatment goal &lt;130 mmHg is recommended for noninstitutionalized ambulatory community-dwelling adults (<math>\geq 65</math> years of age) with an average SBP of <math>\geq 130</math> mmHg.</li> <li>• For older adults (<math>\geq 65</math> years of age) with hypertension and a higher burden of comorbidity and limited life expectancy, clinical judgment, patient preference, and a team-based approach to assess risk/benefit is reasonable for decisions regarding intensity of BP lowering and choice of antihypertensive drugs.</li> </ul> <p><u>Hypertensive Crises</u></p> <ul style="list-style-type: none"> <li>• In adults with a hypertensive emergency, admission to an intensive care unit is recommended for continuous monitoring of BP and target organ damage and for parenteral administration of an appropriate agent.</li> <li>• For adults with a compelling condition (i.e., aortic dissection, severe pre-eclampsia or eclampsia, or pheochromocytoma crisis), SBP should be reduced to &lt;140 mmHg during the first hour and to &lt;120 mmHg in aortic dissection.</li> <li>• For adults without a compelling condition, SBP should be reduced by no more than 25% within the first hours; then, if stable, to 160/100 mmHg within the next two to six hours; and then cautiously to normal during the following 24 to 48 hours.</li> </ul> <p><u>Cognitive Decline and Dementia</u></p> <ul style="list-style-type: none"> <li>• In adults with hypertension, BP lowering is reasonable to prevent cognitive decline and dementia.</li> </ul> <p><u>Patients Undergoing Surgical Procedures</u></p> <ul style="list-style-type: none"> <li>• In patients with hypertension undergoing major surgery who have been on beta-blockers chronically, beta-blockers should be continued.</li> <li>• In patients with hypertension undergoing planned elective major surgery, it is reasonable to continue medical therapy for hypertension until surgery.</li> <li>• In patients with hypertension undergoing major surgery, discontinuation of ACE inhibitors or ARBs perioperatively may be considered.</li> <li>• In patients with planned elective major surgery and SBP <math>\geq 180</math> mmHg or DBP <math>\geq 110</math> mmHg, deferring surgery may be considered.</li> <li>• For patients undergoing surgery, abrupt pre-operative discontinuation of beta-blockers or clonidine is potentially harmful.</li> </ul>

<b>Clinical Guideline</b>	<b>Recommendations</b>
	<ul style="list-style-type: none"><li data-bbox="488 207 1377 264">• Beta-blockers should not be started on the day of surgery in beta-blocker-naïve patients.</li><li data-bbox="488 268 1406 325">• Patients with intraoperative hypertension should be managed with IV medications until such time as oral medications can be resumed.</li></ul>

\*Agent not available in the United States.

### III. Indications

The Food and Drug Administration (FDA)-approved indications for the dihydropyridines are noted in Table 3. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 3. FDA-Approved Indications for the Dihydropyridines<sup>1,6-17</sup>**

Indication(s)	Single Entity Agents							Combination Products			
	Amlodipine	Felodipine	Isradipine	Nicardipine	Nifedipine	Nimodipine	Nisoldipine	Amlodipine and Benazepril	Amlodipine and Olmesartan	Amlodipine and Valsartan	Amlodipine and Valsartan and HCTZ
<b>Angina Pectoris</b>											
Treatment of chronic stable angina	✓ *			✓ (IR)†							
Treatment of chronic stable angina without evidence of vasospasm in patients who remain symptomatic despite adequate doses of β-blockers and/or organic nitrates or who cannot tolerate those agents					✓ (capsule)						
Treatment of vasospastic angina	✓ ‡				✓ (capsule, ER tablet)§						
<b>Coronary Artery Disease (CAD)</b>											
Reduce the risk of hospitalization due to angina and to reduce the risk of a coronary revascularization procedure in patients with recently documented CAD by angiography and without heart failure or an ejection fraction <40%	✓										
<b>Hypertension</b>											
Treatment of hypertension	✓	✓	✓ ¶	✓   #	✓ (ER)		✓	✓ **	✓	✓ ††	✓ †††
<b>Miscellaneous</b>											
Improvement of neurological outcome by reducing the incidence and severity of ischemic deficits in patients with subarachnoid hemorrhage from ruptured intracranial berry aneurysms regardless of their post-ictus neurological condition (i.e., Hunt and Hess Grades I-V)						✓					

\*Alone or in combination with other antianginal agents.

†Alone or in combination with β-blockers.

‡Confirmed or suspected vasospastic angina. Alone or may be used in combination with other antianginal agents.

§Vasospastic angina confirmed by any of the following criteria: 1) classical pattern of angina at rest accompanied by ST segment elevation, 2) angina or coronary artery spasm provoked by ergonovine, or 3) angiographically demonstrated coronary artery spasm.

|| Alone or in combination with other antihypertensive agents.

¶ Alone or in combination with thiazide-type diuretics.

#Cardene IV<sup>®</sup> is indicated for the short term treatment of hypertension when oral therapy is not feasible or not desirable. For prolonged control of blood pressure, transfer patients to oral medication as soon as their clinical condition permits.

\*\*Not adequately controlled on monotherapy with either agent

††Not adequately controlled on monotherapy or as initial therapy in patients likely to need multiple drugs to achieve their blood pressure goals

‡‡This fixed combination drug is not indicated for the initial therapy of hypertension.

ER=extended-release, IR=immediate-release

#### IV. Pharmacokinetics

The pharmacokinetic parameters of the dihydropyridines are listed in Table 4.

**Table 4. Pharmacokinetic Parameters of the Dihydropyridines<sup>2</sup>**

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life (hours)
<b>Single Entity Agents</b>					
Amlodipine	64 to 90	93	Liver, extensive	Renal (70)	30 to 60
Felodipine	13 to 20	>99	Liver, extensive	Renal (70) Feces (10)	26.7 to 33.2
Isradipine	14 to 24 IR: 90 to 95 CR: 15 to 24	95	Liver, complete	Renal (60 to 65) Feces (25 to 30)	8
Nicardipine	35	>95	Liver, nearly 100%	Oral: Renal (60) Feces (35) IV with oral dose: Renal (49) Feces (43 within 96 hours)	IV: 14.4 Oral: 8.6
Nifedipine	IR: rapid and complete ER: complete	92 to 98	Liver, extensive	Renal (80) Feces (20)	2
Nimodipine	13	>95	Liver, extensive	Renal (<1) Feces (% not reported)	1 to 2
Nisoldipine	5	>99	Liver, extensive	Renal (60 to 80) Feces (6 to 12)	13.7 ± 4.3
<b>Combination Products</b>					
Amlodipine and benazepril	64 to 90/≥37	93/93	Liver, extensive (% not reported)/ Liver, extensive (% not reported)	Renal (60% inactive, 10% unchanged)/ Renal (20)	48/ 10 to 11
Amlodipine and olmesartan	64 to 90/26	93/99	Liver, extensive (90)/ Intestinal wall (100)	Renal (10)/ Renal (35 to 50) Feces (50 to 65)	45/7
Amlodipine and valsartan	64 to 90/25	93/95	Liver, extensive (90)/ Not reported	Renal (60)/ Renal (13) Feces (83)	30 to 50/ 6
Amlodipine and valsartan and HCTZ	64 to 90/ 25/ 60 to 80	93/ 95/ 40	Liver, extensive (90)/ Liver, minimal (20)/ Not metabolized	Renal (60)/ Renal (7 to 13) Feces (83)/ Renal (>61)	45/ 6 to 9/ 5.8 to 18.9

CR=controlled-release, ER=extended-release, HCTZ=hydrochlorothiazide, IR=immediate-release

#### V. Drug Interactions

Major drug interactions with the dihydropyridines are listed in Table 5.

**Table 5. Major Drug Interactions with the Dihydropyridines<sup>2</sup>**

Generic Name(s)	Interaction	Mechanism
-----------------	-------------	-----------

Generic Name(s)	Interaction	Mechanism
ARBs (olmesartan, valsartan)	Potassium-sparing diuretics	The risk of hyperkalemia may be increased when potassium-sparing diuretics are co-administered with ACE inhibitors or ARBs.
Amlodipine	Simvastatin	Simvastatin plasma concentrations may be elevated, increasing the risk of toxicity (e.g., myositis, rhabdomyolysis).
ACE inhibitors (benazepril)	Aldosterone blockers	Serious hyperkalemia, possibly with cardiac arrhythmias or arrest, may occur with the combination of aldosterone blockers and benazepril.
ACE inhibitors (benazepril)	Immunosuppressants (Azathioprine and Mercaptopurine)	Concurrent use of immunosuppressants and benazepril may result in myelosuppression.
ACE inhibitors (benazepril)	Sacubitril	Concurrent use of sacubitril and ACE inhibitors may result in increased risk of angioedema.
ACE inhibitors (benazepril)	Potassium-sparing diuretics	The risk of hyperkalemia may be increased when potassium-sparing diuretics are co-administered with ACE inhibitors or ARBs.
Dihydropyridines (amlodipine, felodipine, isradipine, nifedipine, nimodipine, nisoldipine)	Macrolide antibiotics	Inhibition of nifedipine metabolism (CYP3A4) by macrolide and related antibiotics may lead to elevated dihydropyridine plasma concentrations, increasing the pharmacologic effects and risk of adverse reactions (e.g., severe hypotension).
Dihydropyridines (amlodipine)	Rifampin	Concurrent use of amlodipine and rifampin may result in reduced amlodipine efficacy.
Thiazide diuretics (HCTZ)	Dofetilide	Thiazide diuretics may induce hypokalemia which may increase the risk of torsades de pointes.
Thiazide diuretics (HCTZ)	Lithium	Thiazide diuretics may promote enhanced proximal tubular reabsorption of lithium leading to elevated serum concentrations. Thiazide diuretics may increase the therapeutic and toxic effects of lithium.
Dihydropyridines (felodipine, isradipine, nifedipine, nimodipine, nisoldipine)	Azole antifungals	Dihydropyridine serum levels may increase resulting from a decrease metabolism due to CYP3A4 inhibition by azole antifungal agents.
Dihydropyridines (amlodipine, nimodipine)	HCV protease inhibitors	Dihydropyridine serum levels may increase resulting from a decrease metabolism due to CYP3A4 inhibition by protease inhibitors.
Dihydropyridines (amlodipine, nifedipine, nimodipine)	HIV protease inhibitors	Dihydropyridine serum levels may increase resulting from a decrease metabolism due to CYP3A4 inhibition by protease inhibitors.
Dihydropyridines (nimodipine)	Barbiturates	Metabolism of dihydropyridines may be increased due to induction of mixed function oxidases by barbiturates, causing an increase in first-pass metabolism and decreased bioavailability, reducing the effects of dihydropyridines.
ARBs (olmesartan, valsartan)	Aliskiren	Concurrent use of aliskiren may result in an increased risk of hyperkalemia, renal impairment, and hypotension.
ARBs (olmesartan, valsartan)	ACE Inhibitors	Coadministration of ARBs and ACE inhibitors may be associated with an increased risk of renal dysfunction and/or hyperkalemia.
ARBs (olmesartan, valsartan)	Lithium	Elevations in plasma lithium levels may occur.
ARBs (olmesartan,	Potassium	Hyperkalemia, possibly with cardiac arrhythmias or cardiac

Generic Name(s)	Interaction	Mechanism
valsartan)	preparations	arrest, may occur with the combination of olmesartan and potassium preparations.
Dihydropyridines (amlodipine, felodipine, isradipine, nicardipine, nifedipine, nisoldipine)	Clopidogrel	Concurrent use may result in decreased antiplatelet effect and increased risk of thrombotic events.
Dihydropyridines (isradipine)	Mefloquine	Concurrent use of isradipine and mefloquine may result in an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest).
Dihydropyridines (nimodipine)	Hydantoins	Dihydropyridine serum levels may decrease due to increased first-pass metabolism caused by hydantoins.
ACE inhibitors (benazepril)	Aliskiren	The risk of hyperkalemia, renal impairment, and hypotension may be increased when aliskiren is coadministered with benazepril.
ACE inhibitors (benazepril)	mTOR inhibitors (everolimus and sirolimus)	The risk of angioedema may be increased with concurrent administration of mTOR inhibitors and benazepril.
ACE inhibitors (benazepril)	Alteplase	Concurrent use of alteplase and ACE inhibitors may result in an increased risk of orolingual angioedema.
ACE inhibitors (benazepril)	HIV protease inhibitors	Pharmacologic effects of benazepril may be increased by HIV protease inhibitors.
ACE inhibitors (benazepril)	Imidazoles	Imidazoles may increase the plasma concentrations and pharmacologic effects of benazepril.
ACE inhibitors (benazepril)	NSAIDs	The antihypertensive effects of benazepril may be decreased by NSAIDs. Nephrotoxicity associated with benazepril or NSAIDs may be increased by this drug combination.
ACE inhibitors (benazepril)	Lithium	Pharmacologic effects of lithium may be increased by benazepril. Elevated lithium serum concentrations with toxicity may occur.
ACE inhibitors (benazepril)	Potassium preparations	Hyperkalemia, possibly with cardiac arrhythmias or cardiac arrest, may occur with the combination of benazepril and potassium preparations.
ACE inhibitors (benazepril)	Trimethoprim	Hyperkalemia, possibly with cardiac arrhythmias or cardiac arrest, may occur with the combination of trimethoprim and benazepril.
ACE inhibitors (benazepril, felodipine, nimodipine)	Vasopressin receptor antagonists	Plasma concentrations of benazepril may be increased by co-administration of vasopressin receptor antagonists.
Dihydropyridines (isradipine)	Inhaled anesthetics	Concurrent use may result in an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest).
Dihydropyridines (isradipine)	Phenothiazines	Concurrent use of isradipine and phenothiazines may result in an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest).
Dihydropyridines (isradipine)	Tricyclic antidepressants	Concurrent use of isradipine and tricyclic antidepressants may result in an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest).
Dihydropyridines (amlodipine, felodipine, nicardipine)	Cyclosporine	Cyclosporine serum levels may increase due to inhibited metabolism by dihydropyridines.
Dihydropyridines	Carbamazepine	Carbamazepine may decrease plasma concentrations and

Generic Name(s)	Interaction	Mechanism
(felodipine, nifedipine, nimodipine)		effects of nifedipine.
Dihydropyridines (nicardipine, nifedipine)	Fentanyl	Concurrent use of fentanyl and nicardipine may result in severe hypotension.
Dihydropyridines (amlodipine, nicardipine, nifedipine)	Tacrolimus	Tacrolimus serum levels may be elevated due to inhibition of metabolism by dihydropyridines.
Thiazide diuretics (HCTZ)	Diazoxide	The combination of diazoxide with a thiazide diuretic may lead to hyperglycemia through an unknown mechanism; therefore, the combination should be avoided.
Thiazide diuretics (HCTZ)	Digitalis glycosides	Thiazide diuretics may induce electrolyte disturbances which may predispose patients to digitalis-induced arrhythmias.
Dihydropyridines (clevidipine, isradipine, nicardipine, nimodipine, nisoldipine)	Digitalis glycosides	Dihydropyridines may induce electrolyte disturbances which may predispose patients to digitalis-induced arrhythmias.
Calcium channel blockers (amlodipine)	Digoxin	Concurrent use of digoxin and calcium channel blockers may result in increased risk of complete heart block.
Nimodipine	Rifapentine	Rifapentine can reduce plasma concentrations of nimodipine and reduce efficacy levels of nimodipine
Nimodipine	Dexamethasone	Dexamethasone can reduce plasma concentrations of nimodipine and reduce efficacy levels of nimodipine
Nimodipine	rifampin	Rifampin can reduce plasma concentrations of nimodipine and reduce efficacy levels of nimodipine
Nimodipine	Phenobarbital	Phenobarbital can reduce plasma concentrations of nimodipine and reduce efficacy levels of nimodipine
Nimodipine	Phenytoin	Phenytoin can reduce plasma concentrations of nimodipine and reduce efficacy levels of nimodipine
Nimodipine	Nefazodone	Nefazodone can increase serum nimodipine levels
Nimodipine	Delavirdine	Delavirdine can increase serum nimodipine levels.
Nicardipine	Vecuronium	The combination of vecuronium and nicardipine can result in enhanced neuromuscular blockade
Isradipine	Arsenic trioxide	The combination of arsenic trioxide and isradipine can result in an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
Isradipine	Zolmitriptan	The combination of zolmitriptan and isradipine can result in an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
Isradipine	Fluoxetine	The combination of fluoxetine and isradipine can result in an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
Isradipine	Octreotide	The combination of octreotide and isradipine can result in an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
Isradipine	Pentamidine	The combination of isradipine and pentamidine can result in increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
Isradipine	Dolasetron, ondansetron	The combination of isradipine and dolasetron can increase the risk of cardiotoxicity (QT prolongation, torsades de pointes,

Generic Name(s)	Interaction	Mechanism
		cardiac arrest)
Isradipine	Gemifloxacin	The combination of isradipine and Gemifloxacin can increase the risk of cardiotoxicity (QT prolongation, torsades de pointes cardiac arrest)
Dihydropyridines (felodipine, isradipine, nicardipine, nimodipine)	St. John's Wort	St. John's wort may reduce serum levels of dihydropyridines creating subtherapeutic levels of dihydropyridines for antihypertensive activity.
Calcium Channel Blockers (amlodipine, felodipine, isradipine, nicardipine)	Droperidol	Combination of droperidol and calcium channel blockers can increase risk of cardiotoxicity including QT prolongation, torsades de pointes, or cardiac arrest.
Felodipine	Nilotinib	The combination of nilotinib and felodipine can increase exposure of either felodipine or nilotinib.
Dihydropyridines (clevidipine, isradipine, nicardipine, nifedipine, nimodipine, nisoldipine)	Lacosamide	The combination of dihydropyridines and lacosamide can result in prolonged PR interval, AV block, brady cardia, and ventricular tachyarrhythmia
Calcium Channel Blockers (clevidipine, felodipine, isradipine, nicardipine, nifedipine, nimodipine, nisoldipine)	Dantrolene	The combination of dantrolene and calcium channel blockers may result in hyperkalemia with cardiovascular collapse.

ACE inhibitors=angiotensin converting enzyme inhibitors, ARB=angiotensin II receptor blocker, CYP=cytochrome P450 isoenzyme, HCTZ=hydrochlorothiazide, HIV=human immunodeficiency virus, NSAID=nonsteroidal anti-inflammatory drug,

## VI. Adverse Drug Events

The most common adverse drug events reported with the dihydropyridines are listed in Tables 6 and 7. The boxed warnings for the dihydropyridines are listed in Tables 8 through 12.

**Table 6. Adverse Drug Events (%) Reported with the Dihydropyridines (Amlodipine-containing Products)<sup>1,6-17</sup>**

Adverse Events	Single Entity Agents	Combination Products

**Table 8. Boxed Warning for Amlodipine and Benazepril<sup>1</sup>**

WARNING
When pregnancy is detected, discontinue amlodipine and benazepril as soon as possible. Drugs that act directly on the renin-angiotensin system can cause injury and death to the developing fetus.

**Table 9. Boxed Warning for Amlodipine and Olmesartan<sup>1</sup>**

WARNING
When pregnancy is detected, discontinue amlodipine and olmesartan as soon as possible. Drugs that act directly on the renin-angiotensin system can cause injury and death to the developing fetus.

**Table 10. Boxed Warning for Amlodipine and Valsartan<sup>1</sup>**

WARNING
When pregnancy is detected, discontinue amlodipine and valsartan as soon as possible. Drugs that act directly on the renin-angiotensin system can cause injury and death to the developing fetus.

**Table 11. Boxed Warning for Amlodipine and Valsartan and Hydrochlorothiazide<sup>1</sup>**

WARNING
When pregnancy is detected, discontinue amlodipine and valsartan and hydrochlorothiazide as soon as possible. Drugs that act directly on the renin-angiotensin system can cause injury and death to the developing fetus.

**Table 12. Boxed Warning for Nimodipine<sup>1</sup>**

WARNING
Do not administer nimodipine intravenously or by other parenteral routes. Deaths and serious, life-threatening adverse reactions have occurred when the contents of nimodipine capsules have been injected parenterally.

## VII. Dosing and Administration

The usual dosing regimens for the dihydropyridines are listed in Table 14.

**Table 13. Usual Dosing Regimens for the Dihydropyridines<sup>1,2,6-17</sup>**

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
<b>Single Entity Agents</b>			
Amlodipine	<u>Angina pectoris (chronic stable and vasospastic):</u> Suspension, tablet: maintenance, 5 to 10 mg/day; maximum, 10 mg/day	<u>Hypertension in children six to 17 years of age:</u> Suspension, tablet: Initial, 2.5 mg/day; maintenance, 2.5 to 5	Suspension: 1 mg/mL  Tablet: 2.5 mg

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
	<p><u>Coronary artery disease:</u> Suspension, tablet: maintenance, 5 to 10 mg/day; maximum, 10 mg/day</p> <p><u>Hypertension:</u> Suspension, tablet: initial, 2.5 to 5 mg/day maintenance, 5 to 10 mg/day; maximum, 10 mg/day</p>	<p>mg/day; maximum, 5 mg/day</p> <p>Safety and efficacy in children &lt;6 years of age have not been established.</p>	<p>5 mg 10 mg</p>
Felodipine	<p><u>Hypertension:</u> Extended-release tablet: initial, 5 mg/day; maintenance, 2.5 to 10 mg/day</p>	<p>Safety and efficacy in children have not been established.</p>	<p>Extended-release tablet: 2.5 mg 5 mg 10 mg</p>
Isradipine	<p><u>Hypertension:</u> Capsule: initial, 2.5 mg twice daily; maximum, 20 mg/day</p>	<p>Safety and efficacy in children have not been established.</p>	<p>Capsule: 2.5 mg 5 mg</p>
Nicardipine	<p><u>Angina pectoris (chronic stable):</u> Capsule: initial, 20 mg three times daily; maintenance, 20 to 40 mg three times daily</p> <p><u>Hypertension:</u> Capsule: initial, 20 mg three times daily; maintenance, 20 to 40 mg three times daily Injection: titrate dose to achieve the desired blood pressure reduction; individualize dosage depending on the blood pressure to be obtained and the response of the patient</p>	<p>Safety and efficacy in children have not been established.</p>	<p>Capsule: 20 mg 30 mg</p> <p>Injection: 25 mg/10 mL</p>
Nifedipine	<p><u>Angina pectoris (chronic stable):</u> Capsule: initial, 10 mg three times daily; maintenance, 10 to 20 mg three times daily; maximum, 180 mg/day</p> <p>Extended-release tablet: initial, 30 or 60 mg/day; maintenance, 30 to 90 mg/day; maximum, 120 mg/day</p> <p><u>Angina pectoris (vasospastic):</u> Capsule: initial, 10 mg three times daily; maintenance, 20 to 30 mg three to four times daily; maximum, 180 mg/day</p> <p>Extended-release tablet: initial, 30 or 60 mg/day; maintenance, 30 to 90 mg/day; maximum, 120 mg/day</p> <p><u>Hypertension:</u></p>	<p>Safety and efficacy in children have not been established.</p>	<p>Capsule: 10 mg 20 mg</p> <p>Extended-release tablet: 30 mg 60 mg 90 mg</p>

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
	Extended-release tablet: initial, 30 or 60 mg/day; maintenance, 30 to 90 mg/day; maximum, 120 mg/day		
Nimodipine	<u>Subarachnoid hemorrhage:</u> Capsule, solution: 60 mg every four hours for 21 consecutive days	Safety and efficacy in children have not been established.	Capsule: 30 mg  Solution: 60 mg/20 mL
Nisoldipine	<u>Hypertension:</u> Extended-release tablet: initial, 20 mg once daily; maintenance, 20 to 40 mg/day; maximum, 60 mg/day  Extended-release tablet (Sular <sup>®</sup> only): initial, 17 mg once daily; maintenance, 17 to 34 mg/day; maximum, 34 mg/day	Safety and efficacy in children have not been established.	Extended-release tablet: 8.5 mg 17 mg 20 mg 25.5 mg 30 mg 34 mg 40 mg
<b>Combination Products</b>			
Amlodipine and benazepril	<u>Hypertension:</u> Capsule: initial, 2.5-10 mg once daily; maintenance, individualize and adjust dosage according to clinical response, dose once daily	Safety and efficacy in children have not been established.	Capsule: 2.5-10 mg 5-10 mg 5-20 mg 5-40 mg 10-20 mg 10-40 mg
Amlodipine and olmesartan	<u>Hypertension:</u> Tablet: initial, 5-20 mg once daily; maximum, 10-40 mg once daily	Safety and efficacy in children have not been established.	Tablet: 5-20 mg 5-40 mg 10-20 mg 10-40 mg
Amlodipine and valsartan	<u>Hypertension:</u> Tablet: initial, 5-160 mg once daily; maximum, 10-320 mg once daily	Safety and efficacy in children have not been established.	Tablet: 5-160 mg 5-320 mg 10-160 mg 10-320 mg
Amlodipine and valsartan and HCTZ	<u>Hypertension:</u> Tablet: maximum, 10-320-25 mg once daily	Safety and efficacy in children have not been established.	Tablet: 5-160-12.5 mg 5-160-25 mg 10-160-12.5 mg 10-160-25 mg 10-320-25 mg

HCTZ=hydrochlorothiazide

## VIII. Effectiveness

Clinical studies evaluating the safety and efficacy of the dihydropyridines are summarized in Table 14.

**Table 14. Comparative Clinical Trials with the Dihydropyridines**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<b>Angina</b>				
Koenig et al. <sup>37</sup> (1997)  Amlodipine 5 to 10 mg QD for 4 weeks  vs  felodipine ER 5 to 10 mg QD for 4 weeks	DB, PRO, RCT, XO  Patients, age 30 to 80 years, who have a history of angina, a positive exercise-stress test or positive 24-hour ambulatory monitoring, and $\geq 6$ ischemic episodes in 24 hours	N=52  8 weeks	Primary: Number of ST-segment depressions in 24 hours of ambulatory monitoring  Secondary: Total and mean duration of each ST-segment depression episode, maximum ST depression, length of ischemic episode, adverse events	Primary: Significant reductions from baseline were seen in both groups for the number of ST-segment depressions, from 19.9 at baseline for both groups to 2.3 for amlodipine and 2.4 for felodipine ( $P < 0.001$ for both from baseline; $P = 0.83$ between treatments).  Secondary: Total and mean duration of each ST-segment depression episode, maximum ST depression and length of ischemic episode were significantly different from baseline for both treatment groups, but treatments were not significantly different ( $P < 0.001$ for all from baseline, $P = 0.53$ , $P = 0.40$ , $P = 0.68$ , $P = 0.35$ , respectively between treatments).  Adverse event rates similar between the treatments.
Savanitto et al. <sup>38</sup> (1996)  <u>Weeks 1 to 6:</u> Nifedipine 20 mg BID  vs  metoprolol ER 200 mg QD  <u>Weeks 7 to 10:</u>	DB, MC, RCT  Patients with typical anginal symptoms that had been stable for approximately 6 months, who showed a positive response to exercise stress testing with 23 min of exercise tolerance and were in sinus	N=280  6 weeks	Primary: Angina frequency, exercise tolerance, safety  Secondary: Not reported	Primary: At week six, both metoprolol (mean change, -1.95; 95 % CI, -1.25 to -2.64) and nifedipine (mean change, -1.57; 95 % CI, -0.69 to -2.45) significantly reduced the frequency of angina compared to baseline, but there was not a statistical difference between groups. At the end of 10 weeks, there was not a statistical difference observed between the groups.  At week six, both metoprolol and nifedipine significantly increased the mean exercise time to 1-mm ST-segment depression compared to baseline (both $P < 0.01$ ); but metoprolol was significantly more effective than nifedipine ( $P < 0.05$ ).  At week 10, the groups randomized to combination therapy had a further

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>nifedipine 20 mg BID plus placebo vs metoprolol ER 200 mg QD plus placebo vs metoprolol ER 200 mg QD and nifedipine 20 mg BID</p>	<p>rhythm and had an analyzable ST segment on ECG</p>			<p>increase in time to 1-mm ST-segment depression (P&lt;0.05 vs placebo).</p> <p>There were 14 cardiovascular events including one sudden death, three acute myocardial infarctions, eight cases of unstable angina, one of syncope and one of stroke and the incidence of these events did not differ among the treatment groups.</p> <p>Secondary: Not reported</p>
<b>Cardiovascular Outcomes Trials</b>				
<p>Pitt et al.<sup>39</sup> (2000) PREVENT  Amlodipine 5 to 10 mg QD  vs  placebo</p>	<p>DB, MC, PC, RCT  Men and women, age 30 to 80 years with angiographic evidence of CAD, DBP &lt;95 mm Hg, TC 325 mg/dL, FBG &lt;200 mg/dL</p>	<p>N=825  3 years</p>	<p>Primary: Change in mean minimal diameter with a quantitative coronary angiography</p> <p>Secondary: Progression of atherosclerosis in the carotid arteries assessed by B-mode ultrasonography for intimal-medial thicknesses, all-cause mortality, occurrence of major fatal/nonfatal vascular events or procedures, adverse events</p>	<p>Primary: Change, reduction, in the minimal diameter was similar between the amlodipine group and the placebo group (0.084 vs 0.0095 P=0.38).</p> <p>Secondary: Amlodipine treatment significantly decreased the progression of atherosclerosis as compared to placebo treatment, a 0.013 mm decrease for the amlodipine group vs a 0.033 mm increase with placebo (P=0.007).</p> <p>There was no difference in all-cause mortality between amlodipine and placebo.</p> <p>There was no difference in occurrence of fatal and nonfatal vascular events between the treatment groups (HR, 0.82; 95% CI, 0.47 to 1.42).</p> <p>Amlodipine treatment significantly reduced the occurrence of hospitalized CHF and unstable angina (HR, 0.65; 95% CI, 0.47 to 0.91) and coronary revascularizations (HR, 0.57; 95% CI, 0.41 to 0.81) and combined overall procedures (HR, 0.69; 95% CI, 0.52 to 0.92).</p> <p>There was no significant difference between groups in rates of adverse events: cancer rate (HR, 2.13; 95% CI, 0.90 to 5.21) and bleeding episode (HR, 1.42; 95% CI, 0.88 to 2.30).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>Dahlöf et al.<sup>40</sup> (2005) ASCOT-BPLA</p> <p>Amlodipine 5 to 10 mg/day adding perindopril 4 to 8 mg/day as needed</p> <p>vs</p> <p>atenolol 50 to 100 mg/day adding bendroflumethiazide* 1.25 to 2.5 mg/day and potassium as needed</p> <p>If blood pressure was still not achieved, doxazosin 4 to 8 mg/day was added to the regimen.</p>	<p>MC, OL, RCT</p> <p>Patients 40 to 79 years of age with HTN and ≥3 other cardiovascular risk factors (left ventricular hypertrophy, other specified abnormalities on ECG, type 2 diabetes, PAD, history of stroke or TIA, male, age ≥55 years, microalbuminuria or proteinuria, smoking, TC:HDL-C ratio ≥6, or family history of CHD)</p>	<p>N=19,257</p> <p>5.5 years</p>	<p>Primary: Nonfatal MI (including silent MI) and fatal CHD</p> <p>Secondary: All-cause mortality, total stroke, primary end points minus silent MI, all coronary events, total cardiovascular events and procedures, cardiovascular mortality, nonfatal and fatal heart failure, effects on primary end point and on total cardiovascular events and procedures among prespecified subgroups</p> <p>Tertiary: Silent MI, unstable angina, chronic stable angina, PAD, life-threatening arrhythmias, development of diabetes, development of</p>	<p>Primary: No statistically significant difference in nonfatal MI and fatal CHD was reported between the amlodipine plus perindopril group compared to the atenolol plus bendroflumethiazide groups (HR, 0.90; 95% CI, 0.79 to 12; P=0.1052).</p> <p>Secondary: Significantly greater reductions in the following secondary end points were observed with amlodipine plus perindopril compared to atenolol plus bendroflumethiazide: all- cause mortality (P=0.0247), total stroke (P=0.0003), primary end points minus silent MI (P=0.0458), all coronary events (P=0.0070), total cardiovascular events and procedures (P&lt;0.0001), and cardiovascular mortality (P=0.0010).</p> <p>There were no significant differences in nonfatal and fatal heart failure between the two treatment groups (P=0.1257).</p> <p>The study was terminated early due to higher mortality and worse outcomes on several secondary end points observed in the atenolol study group.</p> <p>Tertiary: Significantly greater reductions in the following end points were observed with amlodipine plus perindopril compared to atenolol plus bendroflumethiazide: unstable angina (P=0.0115), PAD (P=0.0001), development of diabetes (P&lt;0.0001), and development of renal impairment (P=0.0187).</p> <p>There were no significant differences in the incidence of silent MI (P=0.3089), chronic stable angina (P=0.8323) or life-threatening arrhythmias (P=0.8009) between the two treatment groups.</p> <p>There was no significant difference in the percent of patients who stopped therapy because of an adverse event between the two treatment groups (overall 25%). There was, however, a significant difference in favor of amlodipine plus perindopril in the proportion of patients who stopped trial therapy because of a serious adverse events (2 vs 3%; P&lt;0.0001).</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>Chapman et al.<sup>41</sup> (2007) ASCOT-BPLA</p> <p>Atenolol 50 to 100 mg titrated to target blood pressure &lt;140/90 mm Hg (or &lt;130/90 mm Hg in diabetic patients); bendroflumethiazide* plus potassium 1.25 to 2.5 mg plus doxazosin were added for additional blood pressure control; if blood pressure remained elevated on the 3 above drugs, spironolactone 25 mg was added to the regimen</p> <p>vs</p> <p>amlodipine 5 to 10 mg titrated to target blood pressure &lt;140/90 mm Hg (or &lt;130/90 mm Hg in diabetic patients); perindopril 4 to 8 mg and doxazosin were added for</p>	<p>Sub analysis of ASCOT-BPLA evaluating effects of spironolactone on treatment-resistant HTN</p> <p>Patients 40 to 79 years of age with HTN and ≥3 cardiovascular risk factors, with SBP ≥160 mm Hg and/or DBP ≥100 mm Hg (not on antihypertensive therapy) or SBP ≥140 mm Hg and/or DBP ≥90 mm Hg (on antihypertensive therapy)</p>	<p>N=1,411</p> <p>1.3 years</p>	<p>renal impairment</p> <p>Primary: Change in DBP and SBP, adverse effects</p> <p>Secondary: Not reported</p>	<p>Primary: Spironolactone-treated patients lead to a significant 21.9 mm Hg reduction in SBP among patients whose blood pressure was previously uncontrolled on at least three other antihypertensive drugs (95% CI, 20.8 to 23.0 mm Hg; P&lt;0.001).</p> <p>Spironolactone-treated patients lead to a significant 9.5 mm Hg reduction in DBP among patients whose blood pressure was previously uncontrolled on at least three other antihypertensive drugs (95% CI, 9.0 to 10.1; P&lt;0.001).</p> <p>Spironolactone-treated patients exhibited small but significant decreases in sodium, LDL-C and TC as well as increases in potassium, glucose, creatinine and HDL-C (P&lt;0.05).</p> <p>The most common adverse effect reported in the trial was gynecomastia in men (P value not reported).</p> <p>Secondary: Not reported</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>additional control; if blood pressure remained elevated on the 3 above drugs, spironolactone 25 mg was added to the regimen</p>				
<p>Nissen et al.<sup>42</sup> (2004) CAMELOT  Amlodipine 10 mg/day  vs  enalapril 20 mg/day  vs  placebo</p>	<p>DB, MC, PC, RCT  Patients 30 to 79 years of age requiring coronary angiography for evaluation for chest pain or PCI and a diastolic pressure &lt;100 mm Hg, with or without treatment</p>	<p>N=1,991  2 years</p>	<p>Primary: Composite of cardiovascular events (cardiovascular death, nonfatal MI, resuscitated cardiac arrest, coronary revascularization, hospitalization for angina pectoris, hospitalization for CHF, fatal or nonfatal stroke or TIA, and any new diagnosis of PVD), nominal change in percent atheroma volume (substudy)  Secondary: Incidence of adverse events; all-cause mortality, incidence of revascularization in vessels that had undergone</p>	<p>Primary: Cardiovascular events occurred in 23.1% of placebo-treated patients, 16.6% amlodipine-treated patients (HR, 0.69; 95% CI, 0.54 to 0.88; P=0.003) and 20.2% enalapril-treated patients (HR, 0.85; 95% CI, 0.67 to 17; P=0.16).  The primary end point comparison for enalapril vs amlodipine was not significant (HR, 0.81; 95% CI, 0.63 to 14; P=0.10).  Secondary: Coronary revascularization was reduced in the amlodipine group from 15.7 to 11.8% (HR, 0.73; 95% CI, 0.54 to 0.98; P=0.03). Hospitalization for angina was reduced in the amlodipine group from 12.8 to 7.7% (HR, 0.58; 95% CI, 0.41 to 0.82; P=0.002).  Individual components of the primary end point generally showed fewer events with enalapril treatment vs placebo, but none of the comparisons reached statistical significance.  For components of the primary end point, only the rate of hospitalization for angina showed a statistically significant difference between amlodipine and enalapril (HR, 0.59; 95% CI, 0.42 to 0.84; P=0.003). A trend toward fewer episodes of revascularization in patients undergoing intervention at baseline was observed for amlodipine vs enalapril (HR, 0.66; 95% CI, 0.40 to 16; P=0.09).  The mean change in percent atheroma volume was 0.5% for amlodipine (P=0.12 vs placebo), 0.8% for enalapril (P=0.32 vs placebo) and 1.3% for placebo. In patients with SBP greater than the mean, the amlodipine group</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
			previous stent placement	<p>showed a significantly slower progression (0.2%) compared to placebo (2.3%; P=0.02). Compared to baseline, intravascular ultrasound showed progression in patients receiving placebo (P&lt;0.001), a trend toward progression with enalapril (P=0.08) and no progression in patients receiving amlodipine (P=0.31). For the amlodipine group, correlation between blood pressure reduction and progression was r=0.19 (P=0.07).</p> <p>Discontinuation from the study for treatment-emergent adverse events was low, averaging 0.4% and not statistically significant between the three treatment groups.</p> <p>The only statistically significant difference in secondary end points was that amlodipine demonstrated a significant reduction in revascularization after previous stent placement compared to placebo (4.1 vs 7.9%; HR, 0.49; 95% CI, 0.31 to 0.78; P=0.002). The rate of revascularization was lower than enalapril (6.2%) but not statistically significant (HR, 0.66; 95% CI, 0.40 to 1.6; P=0.09).</p>
<p>ALLHAT<sup>43</sup> (2002) ALLHAT Amlodipine 2.5 to 10 mg/day vs lisinopril 10 to 40 mg/day vs chlorthalidone 12.5 to 25 mg/day</p>	<p>DB, MC, RCT  Patients ≥55 years with HTN and ≥1 additional CHD risk factor</p>	<p>N=33,357  4.9 years (mean)</p>	<p>Primary: Combined fatal CHD or nonfatal MI  Secondary: All-cause mortality, fatal and nonfatal stroke, combined CHD, combined cardiovascular disease (combined CHD, stroke, treated angina without hospitalization, heart failure, and PAD)</p>	<p>Primary: There were no significant differences in the primary outcome between lisinopril (11.4%), amlodipine (11.3%), and chlorthalidone (11.5%).  Secondary: All-cause mortality did not differ between groups.  Five year SBPs were significantly higher in the lisinopril (2 mm Hg; P&lt;0.001) and amlodipine groups (0.8 mm Hg; P=0.03) compared to chlorthalidone, and five year DBPs were significantly lower with amlodipine (0.8 mm Hg; P&lt;0.001).  Amlodipine had a higher six year rate of heart failure compared to chlorthalidone (10.2 vs 7.7%; RR, 1.38; 95% CI, 1.25 to 1.52).  Lisinopril had a higher six year rate of combined cardiovascular disease (33.3 vs 30.9%; RR, 1.10; 95% CI, 1.05 to 1.16); stroke (6.3 vs 5.6%; RR, 1.15; 95% CI, 1.05 to 1.30) and heart failure (8.7 vs 7.7%; RR, 1.19; 95% CI, 1.07 to 1.31).</p>

Saito et al. <sup>67</sup> (2007) ADVANCE-Combi  Amlodipine 2.5 to 5 mg QD  vs  nifedipine CR 20 to 40 mg QD  Valsartan 40 to 80 mg was added on if blood pressure goal not met.	DB, RCT  Patients with untreated essential HTN with sitting SBP $\geq$ 160 mm Hg or DBP $\geq$ 100 mm Hg; or previously treated with sitting SBP $\geq$ 150 mm Hg or DBP $\geq$ 95 mm Hg	N=514  16 weeks	Primary: Target blood pressure, achievement rate  Secondary: Safety	Primary: Target blood pressure achievement rates were higher for the nifedipine treatment group than the amlodipine group (P<0.001).  Patients in the amlodipine group were more likely to require additional treatment with valsartan or a dose increase of amlodipine (P<0.05).  The reduction in blood pressure from baseline was greater in the nifedipine group (-34.0/-20.1) than in the amlodipine group (-27.0/-15.9; P<0.05).  Secondary: Adverse event rates were not significantly different between the groups, 12.4% in the nifedipine group vs 7.6% of the amlodipine group (P=0.07).
Pepine et al. <sup>68</sup> (2003) CESNA-II  Amlodipine 5 to 10 mg QD  vs  nisoldipine ER 20 to 40 mg QD	DB, DD, PG, MC, RCT  Men and women with HTN (DBP 90-109 mm Hg) and CAD	N=not specified  6 weeks	Primary: Change from baseline in DBP at 6 weeks  Secondary: Exercise duration, antihypertensive responder rate (% of patients with DBP <90 mm Hg), exercise test responder rate (increase in time by 20% and 60 seconds)	Primary: At six weeks, the mean SBP and mean DBP for the two treatment groups were not significantly different from each other and mean reductions in blood pressure were similar: amlodipine SBP/DBP 138/83 mm Hg, a decrease of 13/11 mm Hg, vs nisoldipine 137/81 mm Hg, a decrease of 15/13 mm Hg (P values not significant).  Secondary: Both treatment groups experienced increases in exercise duration, increased by 21 seconds in the amlodipine group and 23 seconds in the nisoldipine group (P=0.268).  Antihypertensive and exercise responder rates were similar between the groups (antihypertensive rates: 78% for amlodipine and 87% for nisoldipine; P>0.05 for both).
Whitcomb et al. <sup>69</sup> (2000)  Amlodipine 2.5 to	DB, DD, MC, RCT  Men and women, age 21 to 75 years,	N=161  8 weeks	Primary: Between treatment comparison of change from	Primary: Treatment with amlodipine resulted in a significantly larger change from baseline in DBP (between-group difference 2.7 mm Hg; P=0.005). However, a pre-specified difference of greater than 5 mm Hg in least mean

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
10 mg QD  vs  nisoldipine ER 10 to 40 mg QD	with HTN		baseline in DBP  Secondary: Change from baseline in SBP, heart rate, percent of patients who responded	squares, here 1.1 to 4.3 mm Hg, showed that the treatments were similar in reduction of DBP.  Secondary: Amlodipine treatment resulted in a significantly larger change from baseline in SBP than nisoldipine treatment (P value not reported, least mean square difference >5 mm Hg).  At week eight, more patients in the amlodipine group were responders, 79%, as compared to the nisoldipine group, 60% (P=0.004).
White et al. <sup>70</sup> (2003) CESNA-III  Amlodipine 5 to 10 mg QD  vs  nisoldipine ER 20 to 60 mg QD	DB, MC, PRO, RCT  African American patients with HTN (blood pressure of 92 mm Hg to 114 mm Hg and SBP <200 mm Hg)	N=192  12 weeks	Primary: ABPM change from baseline in DBP in mean 24 hour period  Secondary: ABPM change in SBP, awake and asleep blood pressure, changes in clinic blood pressure and pulse	Primary: The decrease from baseline in DBP was similar between the groups: -16.0±2.3 mm Hg for nisoldipine and -15.0±2.3 mm Hg for amlodipine (P=0.500).  Secondary: The decrease from baseline in SBP was similar between the groups: -23.0±2.7 mm Hg for nisoldipine and -19.9±2.7 mm Hg for amlodipine (P=0.067).  The changes from baseline in awake and asleep SBP and DBP were not significantly different between the groups except for awake SBP, for which the nisoldipine group had a larger reduction, -19.2 vs -15.9 mm Hg (P=0.045).  The changes from baseline in clinic blood pressure and pulse were similar between the groups (P>0.05 for SBP and DBP; P=0.362).
Lenz et al. <sup>71</sup> (2001)  Amlodipine 5 to 10 mg QD  vs  nisoldipine 10 to 20 mg QD	OL, XO  Patients, 35 to 70 years old, with HTN, (SBP 140 to 179 mm Hg and DBP 90 to 109 mm Hg), stable on amlodipine for ≥3 months prior to	N=21  10 weeks	Primary: 24-hr ABPM  Secondary: Not reported	Primary: No significant difference in ABPM was found after patients switched from amlodipine to nisoldipine for the following: systolic nighttime, daytime and 24-hr blood pressure, diastolic nighttime and daytime blood pressure (P>0.05 for all).  24-hr DBP was significantly lower with amlodipine treatment than with nisoldipine treatment (75±10 vs 77±8.5 mm Hg; P=0.017).  Secondary:

therapy (single entity products)  vs  HCTZ 25 mg QD (existing therapy)			patients achieving blood pressure control (mean sitting blood pressure <140/90 mm Hg), plasma renin activity, safety and tolerability	of HCTZ monotherapy. Combination with aliskiren neutralized this increase and led to an overall significant reduction in plasma renin activity compared to pretreatment baseline (P<0.05) whereas amlodipine and irbesartan led to further significant increases (P<0.05).  All of the study treatments were generally well tolerated. Amlodipine plus HCTZ (45.2%) was associated with a higher incidence of adverse events than the other treatment groups (36.1 to 39.3%), largely due to a higher rate of peripheral edema (11.1 vs 0.8 to 1.6%).
Messerli et al. <sup>79</sup> (2002)  Amlodipine and benazepril 5-10 mg to 5-20 mg QD (fixed-dose combination product)	OL  Patients ≥18 years with mild-to-moderate HTN taking amlodipine 5 to 10 mg with inadequate blood pressure (DBP ≥90 mm Hg, Group 1) or intolerance with amlodipine (DBP ≤90 mm Hg with edema, Group 2)	N=7,912  4 weeks	Primary: Change in mean sitting DBP (group 1), and percentage of patients whose edema improved (group 2)  Secondary: Group 1-change in mean sitting SBP	Primary: In Group 1, mean reduction in DBP at week four was 11.5 mm Hg (95% CI, -11.8 to -11.3 mm Hg; P<0.001). Mean DBP declined from 96.5 (baseline) to 84.9 mm Hg (at 4 weeks).  In Group 2, 85% of patients saw improvement in edema with 42% of patients experiencing complete resolution after receiving combination therapy (95% CI, 83 to 87).  Secondary: In Group 1, mean reduction in SBP at week four was 15.6 mm Hg (95% CI, -16.0 to -15.2 mm Hg; P<0.001).
Chrysant et al. <sup>80</sup> (2012)  Study 1: Benazepril 40 mg/day (Group 1)  vs  amlodipine and benazepril 5-40 mg/day, up titrated to 10-40 mg/day after 4 weeks.	Post-hoc analysis of 2 trials  Patients with HTN	N=1,013  14 weeks	Primary: Change in baseline mean sitting DBP and mean sitting SBP, rate of blood pressure control (<140/90 mm Hg), rate of blood pressure control (mean sitting DBP <90 mm Hg or ≥10 mm Hg decrease from baseline)	Primary: Pooled results demonstrate that combination therapy resulted in significantly greater lowering of mean sitting DBP and mean seated SBP compared to benazepril or amlodipine (P<0.001). Amlodipine and benazepril 10-20 mg/day resulted in significantly greater blood pressure reductions in White patients (mean sitting DBP: 12.99 mm Hg; mean sitting SBP: 13.72 mm Hg) compared to Black patients (8.80 and 8.72 mm Hg) (P<0.004). Amlodipine and benazepril 10-40 mg/day resulted in similar reductions in blood pressure in both White and Black patients.  The proportion of patients who achieved blood pressure control with amlodipine and benazepril 10-40 mg/day was similar between White and Black patients (60.7%), whereas with amlodipine and benazepril 10-20 mg/day the rate of control was higher with White patients (61.2 vs 39.4%);

<p>mg QD</p> <p>vs</p> <p>losartan 50 to 100 mg QD</p> <p>If goal DBP (<math>\leq 90</math> mm Hg) was not attained, drug doses could be doubled and/or HCTZ mg was added.</p>			<p>Secondary: Not reported</p>	<p>significant).</p> <p>Similar reductions in SBP were seen for both treatment groups (P value not significant).</p> <p>The percentage of patients reaching goal DBP (<math>\leq 90</math> mm Hg) or DBP <math>\geq 90</math> mm Hg with a <math>\geq 10</math> mm Hg decrease from baseline) was comparable for the two groups, with 68% of patients in the losartan group and 71% of patients in the amlodipine group reaching goal.</p> <p>Significantly more patients in the amlodipine group had drug-related adverse experiences (27 vs 13%; <math>P=0.029</math>). Edema was more common in patients receiving the amlodipine regimen than in those receiving the losartan regimen (11 vs 1%; <math>P=0.004</math>).</p> <p>Overall QOL was not different in the two treatment groups.</p> <p>Secondary: Not reported</p>
<p>Chrysant et al.<sup>98</sup> (2008) COACH</p> <p>Amlodipine 5 to 10 mg QD and olmesartan 10 to 40 mg</p> <p>vs</p> <p>amlodipine 5 to 10 mg QD</p> <p>vs</p> <p>olmesartan 10 to 40 mg QD</p>	<p>DB, MC, PC, RCT</p> <p>Patients, age 18 years and older, with seated DBP of 95 to 120 mm Hg</p>	<p>N=1,940</p> <p>8 weeks</p>	<p>Primary: Change from baseline in seated DBP at week 8</p> <p>Secondary: Change from baseline in seated SBP at week 8; mean change from baseline in seated DBP and SBP at weeks 2, 4, 6 and 8 without last observation carried forward; proportion of patients achieving</p>	<p>Primary: All active treatments and placebo resulted in significant decreases in seated DBP at week eight (<math>P&lt;0.001</math>). Reductions in seated DBP with monotherapy treatment ranged from -8.3 to -12.7 mm Hg; reductions with combination therapy ranged from -13.8 to -19.0 mm Hg. All combinations reduced seated DBP significantly greater than either component as monotherapy at the same dosage (<math>P&lt;0.001</math>).</p> <p>Secondary: All active treatments and placebo resulted in significant decreases in seated SBP at week eight (<math>P&lt;0.001</math> for treatment, <math>P=0.024</math> for placebo). All combinations reduced seated SBP significantly greater either component as monotherapy at the same dosage (<math>P&lt;0.001</math>).</p> <p>The proportion of patients achieving goal blood pressures were: 20.0 to 36.3% of patients receiving olmesartan monotherapy, 21.1 to 32.5% of patients receiving amlodipine monotherapy, 35.0 to 53.2% of patients receiving combination therapy, and 8.8% of patients receiving placebo.</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs placebo			blood pressure goal (<140/90 mm Hg or <130/80 mm Hg); safety	<p>Combination therapy resulted in significantly greater achievement of goal blood pressure than monotherapy (P&lt;0.005).</p> <p>No difference in overall rates of adverse events across the different treatment groups was seen. Nearly 27% of patients experienced a drug-related adverse event.</p> <p>Changes in laboratory values were not considered clinically significant nor followed a consistent pattern with treatment: none of the changes were considered clinically significant. Platelet counts increased significantly from baseline (statistically) for patients receiving amlodipine, however the increase was &lt;10% and not deemed clinically relevant.</p>
<p>Chrysant et al.<sup>99</sup> (2009) COACH</p> <p>Amlodipine 5 to 10 mg QD and olmesartan 10 to 40 mg</p> <p>HCTZ 12.5 to 25 mg could be added if blood pressure was not controlled (&lt;140/90 mm Hg or &lt;130/80 mm Hg in patients with diabetes).</p>	<p>OL, ES</p> <p>Patients ≥ 18 years of age with essential HTN (seated DBP ≥95 and &lt;120 mm Hg)</p>	<p>N=1,684</p> <p>44 weeks OL therapy (52 weeks total study duration including 8 week DB phase)</p>	<p>Primary: Reduction in mean sitting SBP DBP, change in mean sitting SBP and DBP, percentage of patients achieving blood pressure goal (&lt;140/90 mm Hg or &lt;130/80 mm Hg for patients with diabetes)</p>	<p>Primary: Mean sitting DBP decreased from 101.5 mm Hg at baseline to 81.9 mm Hg and mean sitting SBP decreased from 163.6 mm Hg at baseline to 131.2 mm Hg at week 52.</p> <p>Approximately 31% of patients remained on amlodipine 5 mg and olmesartan 40 mg. Increasing the dose of amlodipine to 10 mg in combination with olmesartan 40 mg produced further decreases in mean sitting DBP of 4.8 mm Hg and mean sitting SBP of 7.3 mm Hg. Addition of HCTZ 12.5 mg to amlodipine 10 mg and olmesartan 40 mg decreased mean sitting DBP by 4.5 mm Hg and mean sitting SBP by 7.7 mm Hg. Doubling the HCTZ dose from 12.5 to 25 mg decreased mean sitting DBP and mean sitting SBP by an additional 6.0 mm Hg and 9.9 mm Hg, respectively. Patients who received the triple therapy had the greatest mean sitting SBP reduction (36.1 mm Hg).</p> <p>Approximately 67% of patients achieved blood pressure goal by week 52. The blood pressure goal achievement was 80% for amlodipine and olmesartan 5/40 mg, 70.6% for amlodipine and olmesartan 10/40 mg, 66.6% for amlodipine and olmesartan and HCTZ 10/40/12.5 mg, and 46.3% for amlodipine and olmesartan and HCTZ 10/40/25 mg.</p> <p>The addition of HCTZ 25 mg enabled more patients to achieve blood pressure targets of &lt;140/90 mm Hg (77.7%), &lt;130/85 mm Hg (47.5%),</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>and &lt;130/80 mm Hg (36.4%) compared to the other treatment regimens.</p> <p>No major safety issues emerged with long-term therapy. The frequency of edema ranged from 8.9% in patients treated with amlodipine 5 mg and olmesartan 40 mg to 14.5% in patients treated with amlodipine 10 mg and olmesartan 40 mg plus HCTZ 25 mg. Other treatment-emergent adverse events experienced by <math>\geq 3\%</math> of patients included upper respiratory tract infection (6.5%), nasopharyngitis (5.2%), extremity pain (4.1%), sinusitis (3.6%), arthralgia (3.3%), and back pain (3.1%). headache (2.0%), hypotension (1.8%), and fatigue (1.6%). The incidence of cough was 0.4%.</p>
<p>Oparil et al.<sup>100</sup> (2009) COACH</p> <p>Amlodipine 5 to 10 mg QD and olmesartan 10 to 40 mg</p> <p>vs</p> <p>amlodipine 5 to 10 mg QD</p> <p>vs</p> <p>olmesartan 10 to 40 mg QD</p> <p>vs</p> <p>placebo</p>	<p>DB, factorial, MC, PC, RCT</p> <p>Patients <math>\geq 18</math> years of age with seated DBP 95 to 120 mm Hg, with a subgroup analysis based on HTN (stage 1: SBP 140 to 159 mm Hg or DBP 90 to 99 mm Hg; stage 2: SBP <math>\geq 160</math> mm Hg or DBP <math>\geq 100</math> mm Hg) and no prior antihypertensive medication</p>	<p>N=1,940</p> <p>8 weeks</p>	<p>Primary: Mean change in DBP and SBP at week 8 for each subgroup</p> <p>Secondary: Proportion of patients achieving blood pressure goal (&lt;140/90 mm Hg or &lt;130/80 mm Hg)</p>	<p>Primary: Reductions in mean DBP as a result of combination treatment were similar between subgroups. Patients with stage 1 HTN achieved reductions of 14.8 to 15.8 mm Hg and patients with stage 2 HTN achieved reductions of 13.6 to 19.8 mm Hg. Reductions in mean SBP as a result of combination treatment resulted in greater reductions in patients with stage 2 HTN (25.1 to 32.7 mm Hg) compared to stage 1 HTN (17.7 to 23.7 mm Hg) (P value not reported).</p> <p>Reductions in mean DBP and SBP were similar between those with no prior antihypertensive treatment and those with prior hypertensive treatment.</p> <p>Secondary: The proportion of patients with stage 1 HTN who received combination treatment and achieved blood pressure goal was 65.6 to 80.0%, compared to 40.5 to 66.7% of those who received monotherapy (P&lt;0.0001 across treatments).</p> <p>The proportion of patients with stage 2 HTN who received combination treatment and achieved BP goal was 40.5 to 49.2%, compared to 13.1 to 29.2% of those who received monotherapy (P&lt;0.0001).</p> <p>Results of patients with baseline SBP <math>\geq 180</math> mm Hg were similar to other subgroups.</p>

Sharma et al. <sup>106</sup> (2007)  Telmisartan and amlodipine 40-5 mg QD (fixed-dose combination)  vs  amlodipine 5 mg QD	DB, MC, RCT  Patients 18 to 65 years of age with established stage 2 uncomplicated essential HTN	N=210  12 weeks	Primary: SBP/DBP reductions and responder rates (SBP/DBP <130/<80 mm Hg)  Secondary: Not reported	Primary: There was a significant reduction from baseline in mean SBP in both groups (telmisartan and amlodipine, from 176.3 to 128.0 mm Hg; amlodipine, from 171.8 to 143.4 mm Hg; both, P<0.05 vs baseline). There was a significant reduction in SBP from baseline in the telmisartan and amlodipine and amlodipine groups (-27.4 and -16.6%, respectively; P<0.05 within group and between groups).  There was a significant reduction from baseline in mean DBP in both treatment groups (telmisartan and amlodipine, from 100.9 to 93.8 mm Hg; amlodipine, from 99.7 to 94.3 mm Hg; both, P<0.05). There was a 20.2% reduction in mean DBP in the telmisartan and amlodipine group, which was significantly greater compared to the reduction of 12.7% observed in the amlodipine group (P<0.05 between groups and within both groups).  A total of 87.3% of patients receiving telmisartan and amlodipine reached the target SBP/DBP goal, compared to 69.3% of patients receiving amlodipine (P<0.05).  A total of 16.0% of patients in the telmisartan and amlodipine group experienced adverse events compared to 15.4% of patients in the amlodipine group (P value not significant). The most common adverse events in the telmisartan and amlodipine group were peripheral edema (8.5%), headache (5.7%), dizziness and cough (3.8%), and diarrhea (1.9%).  Secondary: Not reported
Neutel et al. <sup>107</sup> (2012) TEAMSTA  Telmisartan and	DB, MC, PG, RCT  Patients ≥18 years of age with severe HTN	N=858  8 weeks	Primary: Change in baseline blood pressure, blood pressure goal and response rates	Primary: Reductions in seated trough cuff blood pressure (-47.5/-18.7 mm Hg) were significantly greater with combination therapy compared to telmisartan (P<0.001) or amlodipine (P=0.002). Significant reductions with combination therapy were observed at one, two, four, and six weeks.

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
amlodipine 80-10 mg QD (fixed-dose combination product)  vs  telmisartan 80 mg QD  vs  amlodipine 10 mg QD			Secondary: Safety	Blood pressure goal and response rates were consistently higher with combination therapy (50.4 and 91.4 to 99.7%) compared to monotherapy with either agent (24.1 and 69.3 to 91.5% and 35.6 and 83.9 to 98.5%).  Secondary: Combination therapy was well tolerated and fewer adverse events were reported with combination therapy compared to amlodipine (12.6 vs 16.4%). Peripheral edema was reported more frequently with amlodipine compared to combination therapy (13.2 vs 9.3%).
Maciejewski et al. <sup>108</sup> (2006)  Amlodipine 5 to 10 mg QD  vs  valsartan 80 to 160 mg QD  If blood pressure exceeded 140/90 while on highest treatment dose, HCTZ 12.5mg/day was added to the regimen.	DB, PRO, RCT, XO  African-Americans, older than 35 years, with baseline blood pressure >140/90 mm Hg and not on antihypertensive treatment	N=20  8 to 10 weeks for each arm with 2 week washout period before crossover	Primary: Comparison of 24-hr ABPM recordings  Secondary: Magnitude of change from baseline in SBP and DBP with each treatment, percent of patients who achieved goal <140/<90 with each treatment based on clinic blood pressure measurements	Primary: There was no difference between the groups based on 24-hr ABPM: SBP amlodipine 130±8 vs valsartan 127±17 (P=0.350) and DBP amlodipine 82±5 vs valsartan 84±16 (P=0.430).  Secondary: There was no difference between groups in magnitude of change from baseline in blood pressure (amlodipine -25±8/-18±7 vs valsartan -25±9/-16±7; P=0.61), and in percent of patients achieving goal blood pressure, 70% in the valsartan group and 75% in the amlodipine group (P=0.62).
Ichihara et al. <sup>109</sup> (2006)  Amlodipine 2.5 to 10 mg QD	RCT  Patients with untreated HTN (clinic SBP >140	N=100  12 months	Primary: ABPM and clinic blood pressure  Secondary:	Primary: Both treatments resulted in significant decreases in blood pressure, both ambulatory and clinic, over 12 months from baseline; blood pressure decreases were similar between treatment groups (between treatments: clinic SBP P=0.34; clinic DBP P=0.85; 24 hour ABPM P=0.14).

## **Additional Evidence**

### Dose Simplification

Taylor et al. evaluated adherence rates in patients receiving a fixed-dose combination of amlodipine and benazepril compared to patients receiving an ACE inhibitor and a long-acting dihydropyridine calcium-channel blocking agent as separate formulations. There was no significant difference in adherence in younger subjects (18 to 39 year olds); however, overall adherence was higher in patients receiving amlodipine/benazepril fixed-dose combination product compared to those receiving separate formulations (80.8 vs 73.8%;  $P < 0.001$ ).<sup>144</sup> Dickson et al. also evaluated adherence rates with the fixed-dose combination of amlodipine/benazepril compared to the administration of an ACE inhibitor and dihydropyridine calcium-channel blocking agent as separate formulations in an elderly Medicaid population. Over a 12 month period, adherence rates were higher in patients receiving the fixed-dose combination product compared to those receiving separate formulations (63.4 vs 49.0%;  $P < 0.0001$ ).<sup>145</sup> Gerbino et al. assessed adherence rates in patients receiving the fixed-dose combination of amlodipine/benazepril or an ACE inhibitor and dihydropyridine calcium-channel blocking agent administered as separate formulations. Adherence rates were 69.2% for patients who received the antihypertensive agents as separate formulations compared to 87.9% for patients receiving the fixed-dose combination product ( $P < 0.0001$ ).<sup>146</sup>

### Stable Therapy

Lenz et al. compared the 24-hour blood pressure control in patients stabilized on amlodipine who were then converted to nisoldipine. After three months, blood pressure control was similar between treatments, except for average 24-hour diastolic blood pressure, where nisoldipine treatment resulted in slightly greater readings (by 2 mm Hg).<sup>71</sup> Gustin et al. reviewed medical records of hypertensive patients who were switched from long-acting nifedipine to felodipine. This resulted in slightly lower diastolic blood pressure measurements (78 vs 80 mm Hg;  $P < 0.05$ ). Adverse events and supplemental medication use were similar between the agents.<sup>125</sup> Sapienza et al. measured the impact of converting long-term care patients previously on high dose calcium-channel blocking agents or dual therapy with an ACE inhibitor and calcium-channel blocking agents to the fixed-dose combination of amlodipine/benazepril. There was no significant change in blood pressure following the conversion; however, there was a significant reduction in the number of patients reporting  $\geq 1$  drug-related adverse event (22 vs 4;  $P < 0.05$ ).<sup>147</sup>

### Impact on Physician Visits

Sheehy et al. conducted a comparative review of patients receiving amlodipine or felodipine. The investigators found an increased number of specialist visits in the amlodipine group (odds ratio, 1.14; 95% confidence interval, 1.8 to 1.20); however, this same group of patients receiving amlodipine had significantly better compliance and refill rates and fewer medication switches.<sup>62</sup>

## **IX. Cost**

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of '\$' signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 15. Relative Cost of the Dihydropyridines**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost
<b>Single Entity Agents</b>				
Amlodipine	suspension, tablet	Katerzia <sup>®</sup> , Norvasc <sup>®</sup> *	\$\$\$\$\$	\$
Felodipine	extended-release tablet	N/A	N/A	\$\$
Isradipine	capsule	N/A	N/A	\$\$\$\$\$
Nicardipine	capsule*, injection*	N/A	N/A	\$\$\$\$\$
Nifedipine	capsule, extended-release tablet	Adalat CC <sup>®</sup> *, Procardia XL <sup>®</sup> *	\$\$\$\$\$	\$
Nimodipine	capsule*, solution	Nymalize <sup>®</sup>	\$\$\$\$\$	\$\$\$\$\$
Nisoldipine	extended-release tablet*	Sular ER <sup>®</sup> *	\$\$\$\$\$	\$\$\$\$\$
<b>Combination Products</b>				
Amlodipine and benazepril	capsule	Lotrel <sup>®</sup> *	\$\$\$\$\$	\$
Amlodipine and olmesartan	tablet	Azor <sup>®</sup> *	\$\$\$\$\$	\$
Amlodipine and valsartan	tablet	Exforge <sup>®</sup> *	\$\$\$\$\$	\$\$
Amlodipine, valsartan, and HCTZ	tablet	Exforge HCT <sup>®</sup> *	\$\$\$\$\$	\$

\*Generic is available in at least one dosage form or strength.

HCTZ=hydrochlorothiazide, N/A=not available

## X. Conclusions

All of the dihydropyridines, with the exception of nimodipine, are approved for the treatment of hypertension. Amlodipine, nicardipine, and nifedipine are also indicated for the treatment of angina. Additionally, amlodipine reduces the risk of hospitalization due to angina and reduces the risk of coronary revascularization procedures in patients with recently documented coronary artery disease.<sup>1,2,6-17</sup> Amlodipine is available in combination with benazepril, olmesartan, valsartan, or valsartan-hydrochlorothiazide. It should be noted that the amlodipine and telmisartan fixed-dose combination product and the amlodipine, olmesartan, and hydrochlorothiazide fixed-dose combination product are included in the angiotensin II receptor antagonists class review (AHFS Class 243208). All of the products with the exception of clevidipine is available in a generic formulation.

There are several national and international guidelines that provide recommendations regarding the use of calcium-channel blocking agents.<sup>18-36</sup> For the treatment of chronic angina,  $\beta$ -blockers are recommended as initial therapy; however, long-acting calcium-channel blocking agents may be used if  $\beta$ -blockers are contraindicated or if additional therapy is required.<sup>18-24</sup> Calcium-channel blocking agents are recommended as initial therapy in patients with variant/vasospastic angina.<sup>19,22</sup> For the treatment of heart failure, ACE inhibitors, ARBs, aldosterone antagonists, and isosorbide dinitrate/hydralazine are recommended as initial therapy. In general, calcium-channel blocking agents are not recommended in the management of heart failure.<sup>26-27</sup> There are several published guidelines on the treatment of hypertension. Thiazide-type diuretics are frequently recommended as initial therapy in patients with uncomplicated hypertension.<sup>28-34</sup> According to the National Heart, Lung, and Blood Institute's Eighth Report of The Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High

Blood Pressure (JNC 8), thiazide-type diuretics should be utilized first-line for most patients with hypertension, either alone or in combination with another hypertensive from a different medication class (e.g., ACE inhibitors, ARBs,  $\beta$ -blockers, calcium channel blockers).<sup>29</sup> Several guidelines consistently recommend that the selection of an antihypertensive agent be based on compelling indications for use.<sup>28-34,36</sup> Most patients will require more than one antihypertensive medication to achieve blood pressure goals.<sup>28-34,36</sup>

Numerous clinical trials have shown that the dihydropyridines can effectively lower systolic and diastolic blood pressure when administered alone or in combination with other agents. In trials comparing combination therapy to monotherapy, the more aggressive treatment regimens lowered blood pressure to a greater extent than the less-intensive treatment regimens. Some comparative trials have demonstrated slight differences in blood pressure effects among the various dihydropyridines; however, the clinical significance of these differences remains to be established.<sup>62-131</sup> Most patients will require more than one antihypertensive agent to achieve blood pressure goals.<sup>28-34</sup> The use of a fixed-dose combination product may simplify the treatment regimen and improve adherence.<sup>30,31,144-146</sup> However, there are no prospective, randomized trials that have demonstrated better clinical outcomes with a fixed-dose combination product compared to the coadministration of the individual components as separate formulations. The dihydropyridines have been shown to favorably affect cardiovascular morbidity and mortality, and several studies have demonstrated comparable efficacy with  $\beta$ -blockers, diuretics, ACE inhibitors, ARBs.<sup>39-61</sup>

There is insufficient evidence to support that one brand dihydropyridine is safer or more efficacious than another. Formulations without a generic alternative should be managed through the medical justification portion of the prior authorization process.

Therefore, all brand dihydropyridines within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

## **XI. Recommendations**

No brand dihydropyridine is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Calcium-Channel Blocking Agents, Miscellaneous  
AHFS Class 242892  
May 4, 2022**

**I. Overview**

The movement of calcium ions is essential for the function of all types of muscle, including cardiac and vascular smooth muscle. When this flow is reduced, the result is a weakening of muscle contraction and relaxation of muscle tissue.<sup>1-3</sup> Relaxation of coronary vascular smooth muscle increases the flow of oxygenated blood into the myocardium, while relaxation of arteriolar smooth muscle decreases peripheral vascular resistance. Both coronary and systemic vasodilation serve to reduce cardiac workload. The calcium-channel blocking agents include dihydropyridines and miscellaneous agents (nondihydropyridines). Although they have different binding sites on the L-type calcium channel, both block the transmembrane influx of calcium ions into cardiac and vascular smooth muscle. The nondihydropyridines also block the T-type calcium channel in the atrioventricular node.<sup>1-5</sup>

The miscellaneous calcium-channel blocking agents include diltiazem and verapamil, which are approved for the treatment of angina, arrhythmias, and hypertension.<sup>1,2,6-14</sup> Diltiazem is a potent coronary vasodilator, but is only a mild arterial vasodilator. Although it decreases atrioventricular (AV) node conduction, diltiazem does not have negative inotropic properties.<sup>1,2,6-14</sup> Verapamil dilates coronary and peripheral arteries. It also slows conduction through the AV node, and has negative inotropic and chronotropic effects.<sup>1,2,6-14</sup> Both diltiazem and verapamil are available in a variety of modified-release delivery systems that alter their pharmacokinetic properties, including onset and duration of action.<sup>1,2</sup>

The miscellaneous calcium-channel blocking agents that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. Diltiazem and verapamil are available in generic formulations. This class was last reviewed in February 2020.

**Table 1. Calcium-Channel Blocking Agents, Miscellaneous Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
Diltiazem	extended-release capsule, extended-release tablet, injection, tablet	Cardizem <sup>®</sup> *, Cardizem CD <sup>®</sup> *, Cardizem LA <sup>®</sup> *, Matzim LA <sup>®</sup> *, Tiazac <sup>®</sup> *	diltiazem
Verapamil	extended-release capsule, extended-release tablet, injection, tablet	Calan SR <sup>®</sup> *, Verelan <sup>®</sup> *, Verelan PM <sup>®</sup> *	verapamil

\*Generic is available in at least one dosage form or strength.  
PDL=Preferred Drug List

**II. Evidence-Based Medicine and Current Treatment Guidelines**

Current treatment guidelines that incorporate the use of the miscellaneous calcium-channel blocking agents are summarized in Table 2.

**Table 2. Treatment Guidelines Using the Calcium-Channel Blocking Agents, Miscellaneous**

Clinical Guideline	Recommendations
American College of Cardiology/ American Heart Association: <b>2007 Chronic Angina Focused Update of the 2002 Guidelines for the</b>	<ul style="list-style-type: none"> <li>Aspirin should be started at 75 to 162 mg/day and continued indefinitely in all patients, unless contraindicated.</li> <li>Use of warfarin in conjunction with aspirin and/or clopidogrel is associated with an increased risk of bleeding and should be monitored closely.</li> <li>Patients with hypertension and established coronary artery disease (CAD) should be treated with blood pressure medication(s) as tolerated, including angiotensin converting enzyme (ACE) inhibitors and/or <math>\beta</math>-adrenergic antagonists (<math>\beta</math>-blockers) with the addition of other medications as needed to achieve blood pressure goals of</li> </ul>

Clinical Guideline	Recommendations
<b>Management of Patients With Chronic Stable Angina (2007)<sup>15</sup></b>	<p>&lt;140/90 or &lt;130/80 mm Hg for patients with chronic kidney disease or diabetes.</p> <ul style="list-style-type: none"> <li>• Long-acting calcium channel blocking agents or long-acting nitrates may be used if <math>\beta</math>-blockers are contraindicated. Immediate-release and short-acting dihydropyridine calcium channel blockers can increase adverse cardiac events and should not be used.</li> <li>• Long-acting calcium channel blockers or long-acting nitrates may be used with <math>\beta</math>-blockers if initial treatment is not successful.</li> <li>• ACE inhibitors should be used indefinitely in patients with a left ventricular ejection fraction (LVEF) <math>\leq 40\%</math> and in those with hypertension, diabetes or chronic kidney disease, unless contraindicated.</li> <li>• ACE inhibitors should also be used indefinitely in patients at lower risk (mildly reduced or normal LVEF in whom cardiovascular risk factors remain well controlled and revascularization has been performed), unless contraindicated.</li> <li>• Angiotensin II receptor blockers (ARBs) are recommended in patients with hypertension, those who have an indication for an ACE inhibitor and are intolerant to them, who have heart failure, or who have had a myocardial infarction (MI) and have a LVEF <math>\leq 40\%</math>.</li> <li>• ARBs may be considered in combination with an ACE inhibitor for heart failure due to left ventricular systolic dysfunction.</li> <li>• Aldosterone blockade is recommended in patients post-MI without significant renal dysfunction or hyperkalemia who are already receiving therapeutic doses of an ACE inhibitor and a <math>\beta</math>-blocker, have a LVEF <math>\leq 40\%</math> and have either diabetes or heart failure.</li> <li>• It is beneficial to start and continue <math>\beta</math>-blocker therapy indefinitely in all patients who have had a MI, acute coronary syndrome or left ventricular dysfunction with or without heart failure symptoms, unless contraindicated.</li> <li>• Annual influenza vaccination is recommended in patients with cardiovascular disease.</li> </ul>
<b>European Society of Cardiology: Guidelines for the Diagnosis and Management of Chronic Coronary Syndromes (2019)<sup>16</sup></b>	<p><b>Pharmacological management of stable coronary artery disease (CAD) patients</b></p> <ul style="list-style-type: none"> <li>• The two aims of the pharmacological management of stable CAD patients are to obtain relief of symptoms and to prevent CV events.</li> <li>• Optimal medical treatment indicates at least one drug for angina/ischaemia relief plus drugs for event prevention.</li> <li>• It is recommended to educate patients about the disease, risk factors and treatment strategy.</li> <li>• It is indicated to review the patient's response soon after starting therapy.</li> <li>• Concomitant use of a proton pump inhibitor is recommended in patients receiving aspirin monotherapy, DAPT, or DOAC monotherapy who are at high risk of gastrointestinal bleeding.</li> <li>• Lipid-lowering drugs: if goals are not met on maximum tolerated dose of a statin, consideration of combination therapy with ezetimibe or a PCSK9 inhibitor is recommended</li> <li>• ACE inhibitors should be considered in patients at a very high risk of cardiovascular adverse events</li> <li>• Angina/ischemia relief:             <ul style="list-style-type: none"> <li>○ Short-acting nitrates are recommended.</li> <li>○ First-line treatment is indicated with <math>\beta</math>-blockers and/or calcium channel blockers to control heart rate and symptoms.</li> <li>○ Long-acting nitrates should be considered as a second-line treatment option when initial therapy with a beta-blocker and/or a non-DHP-calcium channel blocker is contraindicated, poorly tolerated, or inadequate in controlling angina symptoms</li> <li>○ Nicorandil, ranolazine, ivabradine, or trimetazidine should be considered as a second-line treatment to reduce angina frequency and improve exercise tolerance in subjects who cannot tolerate, have contraindications to, or</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>whose symptoms are not adequately controlled by beta-blockers, CCBs, and long-acting nitrates.</p> <ul style="list-style-type: none"> <li>○ According to comorbidities/tolerance, it is indicated to use second-line therapies as first-line treatment in selected patients.</li> <li>○ In asymptomatic patients with large areas of ischaemia (&gt;10%) <math>\beta</math>-blockers should be considered.</li> <li>○ In patients with vasospastic angina, calcium channel blockers and nitrates should be considered and <math>\beta</math>-blockers avoided.</li> </ul> <ul style="list-style-type: none"> <li>● Event prevention: <ul style="list-style-type: none"> <li>○ Low-dose aspirin daily is recommended in all stable CAD patients.</li> <li>○ Clopidogrel is indicated as an alternative in case of aspirin intolerance.</li> <li>○ Statins are recommended in all stable CAD patients.</li> <li>○ It is recommended to use ACE inhibitors (or ARBs) if presence of other conditions (e.g., heart failure, hypertension or diabetes).</li> </ul> </li> </ul> <p><u>Treatment in patients with microvascular angina</u></p> <ul style="list-style-type: none"> <li>● It is recommended that all patients receive secondary prevention medications including aspirin and statins.</li> <li>● <math>\beta</math>-blockers are recommended as a first-line treatment.</li> <li>● Calcium antagonists are recommended if <math>\beta</math>-blockers do not achieve sufficient symptomatic benefit or are not tolerated.</li> <li>● ACE inhibitors or nicorandil may be considered in patients with refractory symptoms.</li> <li>● Xanthine derivatives or nonpharmacological treatments such as neurostimulatory techniques may be considered in patients with symptoms refractory to the above listed drugs.</li> </ul> <p><u>Stenting and peri-procedural antiplatelet strategies in stable CAD patients</u></p> <ul style="list-style-type: none"> <li>● Drug-eluting stent (DES) is recommended in stable CAD patients undergoing stenting if there is no contraindication to prolonged dual antiplatelet therapy (DAPT).</li> <li>● Aspirin is recommended for elective stenting.</li> <li>● Clopidogrel is recommended for elective stenting.</li> <li>● Prasugrel or ticagrelor should be considered in patients with stent thrombosis on clopidogrel without treatment interruption.</li> <li>● GP IIb/IIIa antagonists should be considered for bailout situation only.</li> <li>● Platelet function testing or genetic testing may be considered in specific or high-risk situations (e.g., prior history of stent thrombosis; compliance issue; suspicion of resistance; high bleeding risk) if results may change the treatment strategy.</li> <li>● Prasugrel or ticagrelor may be considered in specific high-risk situations of elective stenting (e.g., left main stenting, high risk of stent thrombosis, diabetes).</li> <li>● Pretreatment with clopidogrel (when coronary anatomy is not known) is not recommended.</li> <li>● Routine platelet function testing (clopidogrel and aspirin) to adjust antiplatelet therapy before or after elective stenting is not recommended.</li> <li>● Prasugrel or ticagrelor is not recommended in low-risk elective stenting.</li> <li>● After uncomplicated PCI, early cessation (<math>\leq 1</math> week) of aspirin, and continuation of dual therapy with oral anticoagulation therapy and clopidogrel should be considered if the risk of stent thrombosis is low</li> <li>● Triple therapy with aspirin, clopidogrel, and a DOAC for <math>\geq 1</math> month should be considered when the risk of stent thrombosis outweighs the bleeding risk, with a total of no more than six months</li> </ul> <p><u>Follow-up of revascularized stable coronary artery disease patients</u></p> <ul style="list-style-type: none"> <li>● It is recommended that all revascularized patients receive a secondary prevention</li> </ul>

Clinical Guideline	Recommendations
	<p>and be scheduled for follow-up visit.</p> <ul style="list-style-type: none"> <li>• It is recommended to instruct patients before discharge about return to work and resumption of full activities. Patients have to be advised to seek immediate medical contact if symptoms (re-) occur.</li> <li>• Single antiplatelet therapy, usually aspirin, is recommended indefinitely.</li> <li>• DAPT is indicated after bare metal stent (BMS) for at least one month.</li> <li>• DAPT is indicated for six to 12 months after second generation DES.</li> <li>• DAPT may be used for more than one year in patients at high ischemic risk (e.g., stent thrombosis, recurrent acute coronary syndrome on DAPT, post MI/diffuse CAD) and low bleeding risk.</li> <li>• DAPT for one to three months may be used after DES implantation in patients at high bleeding risk or with undeferrable surgery or concomitant anticoagulant treatment.</li> </ul> <p><u>Antithrombotic therapy in patients with chronic coronary syndrome:</u></p> <ul style="list-style-type: none"> <li>• Addition of a second antithrombotic drug to aspirin for long-term secondary prevention should be considered in patients with at least a moderately increased risk of ischemic events and without high bleeding risk</li> <li>• When oral anticoagulation is initiated in patients with AF, a DOAC is recommended in preference to VKA therapy.</li> </ul>
<p>American College of Physicians/          American College of Cardiology Foundation/          American Heart Association/          American Association for Thoracic Surgery/          Preventive Cardiovascular Nurses Association/          Society of Thoracic Surgeons:  <b>Management of Stable Ischemic Heart Disease (2012)</b><sup>17</sup></p>	<p><u>Medical therapy to prevent MI and death in patients with stable IHD</u></p> <ul style="list-style-type: none"> <li>• Aspirin 75 to 162 mg daily should be continued indefinitely in the absence of contraindications.</li> <li>• Treatment with clopidogrel is a reasonable option when aspirin is contraindicated.</li> <li>• Dipyridamole should not be used as antiplatelet therapy.</li> <li>• Beta-blocker therapy should be initiated and continued for three years in all patients with normal left ventricular (LV) function following MI or acute coronary syndromes.</li> <li>• Metoprolol succinate, carvedilol, or bisoprolol should be used for all patients with systolic LV dysfunction (ejection fraction <math>\leq 40\%</math>) with heart failure or prior MI, unless contraindicated.</li> <li>• ACE inhibitors should be prescribed in all patients with stable IHD who also have hypertension, diabetes, LV systolic dysfunction (ejection fraction <math>\leq 40\%</math>), and/or chronic kidney disease, unless contraindicated.</li> <li>• Angiotensin-receptor blockers (ARBs) are recommended for patients with stable IHD who have hypertension, diabetes, LV systolic dysfunction, or chronic kidney disease and have indications for, but are intolerant of, ACE inhibitors.</li> <li>• Patients should receive an annual influenza vaccine.</li> </ul> <p><u>Medical therapy for relief of symptoms in patients with stable IHD</u></p> <ul style="list-style-type: none"> <li>• Beta-blockers are recommended as initial therapy for relief of symptoms.</li> <li>• Calcium channel blockers or long-acting nitrates should be prescribed for relief of symptoms when <math>\beta</math>-blockers are contraindicated or cause unacceptable side effects.</li> <li>• Calcium channel blockers or long-acting nitrates, in combination with <math>\beta</math>-blockers, should be prescribed for relief of symptoms when initial treatment with <math>\beta</math>-blockers is unsuccessful.</li> <li>• Nitroglycerin or nitroglycerin spray should be used for immediate relief of angina.</li> <li>• Ranolazine is a fourth-line agent reserved for patients who have contraindications to, do not respond to, or cannot tolerate <math>\beta</math>-blockers, calcium-channel blockers, or long-acting nitrates.</li> </ul>
<p>American College of Cardiology Foundation/          American Heart Association:</p>	<p><u>Early hospital care- standard medical therapies</u></p> <ul style="list-style-type: none"> <li>• Supplemental oxygen should be administered to patients with non-ST-elevation acute coronary syndrome (NSTE-ACS) with arterial oxygen saturation <math>&lt; 90\%</math>, respiratory distress, or other high risk features of hypoxemia.</li> <li>• Anti-ischemic and analgesic medications</li> </ul>

Clinical Guideline	Recommendations
<p><b>2014 American Heart Association/ American College of Cardiology Foundation Guideline for the Management of Patients With Non–ST-Elevation Acute Coronary Syndromes (2014)<sup>18</sup></b></p>	<ul style="list-style-type: none"> <li>○ Nitrates <ul style="list-style-type: none"> <li>▪ Patients with NSTEMI-ACS with continuing ischemic pain should receive sublingual nitroglycerin (0.3 to 0.4 mg) every 5 minutes for up to three doses, after which an assessment should be made about the need for intravenous nitroglycerin.</li> <li>▪ Intravenous nitroglycerin is indicated for patients with NSTEMI-ACS for the treatment of persistent ischemia, heart failure, or hypertension.</li> <li>▪ Nitrates should not be administered to patients who recently received a phosphodiesterase inhibitor, especially within 24 hours of sildenafil or vardenafil, or within 48 hours of tadalafil.</li> </ul> </li> <li>○ Analgesic therapy <ul style="list-style-type: none"> <li>▪ In the absence of contraindications, it may be reasonable to administer morphine sulphate intravenously to patients with NSTEMI-ACS if there is continued ischemic chest pain despite treatment with maximally tolerated anti-ischemic medications.</li> <li>▪ Nonsteroidal anti-inflammatory drugs (NSAIDs) (except aspirin) should not be initiated and should be discontinued during hospitalization due to the increased risk of major adverse cardiac event associated with their use.</li> </ul> </li> <li>○ Beta-adrenergic blockers <ul style="list-style-type: none"> <li>▪ Oral <math>\beta</math>-blocker therapy should be initiated within the first 24 hours in patients who do not have any of the following: 1) signs of HF, 2) evidence of low-output state, 3) increased risk for cardiogenic shock, or 4) other contraindications to <math>\beta</math>-blockade (e.g., PR interval <math>&gt;0.24</math> second, second- or third-degree heart block without a cardiac pacemaker, active asthma, or reactive airway disease)</li> <li>▪ In patients with concomitant NSTEMI-ACS, stabilized heart failure, and reduced systolic function, it is recommended to continue <math>\beta</math>-blocker therapy with one of the three drugs proven to reduce mortality in patients with heart failure: sustained-release metoprolol succinate, carvedilol, or bisoprolol.</li> <li>▪ Patients with documented contraindications to <math>\beta</math>-blockers in the first 24 hours should be re-evaluated to determine subsequent eligibility.</li> </ul> </li> <li>○ Calcium channel blockers (CCBs) <ul style="list-style-type: none"> <li>▪ In patients with NSTEMI-ACS, continuing or frequently recurring ischemia, and a contraindication to <math>\beta</math>-blockers, a nondihydropyridine CCB (e.g., verapamil or diltiazem) should be given as initial therapy in the absence of clinically significant LV dysfunction, increased risk for cardiogenic shock, PR interval <math>&gt;0.24</math> seconds, or second or third degree atrioventricular block without a cardiac pacemaker.</li> <li>▪ Oral nondihydropyridine calcium antagonists are recommended in patients with NSTEMI-ACS who have recurrent ischemia in the absence of contraindications, after appropriate use of <math>\beta</math>-blockers and nitrates.</li> <li>▪ CCBs are recommended for ischemic symptoms when <math>\beta</math>-blockers are not successful, are contraindicated, or cause unacceptable side effects.</li> <li>▪ Long-acting CCBs and nitrates are recommended in patients with coronary artery spasm.</li> <li>▪ Immediate-release nifedipine should not be administered to patients with NSTEMI-ACS in the absence of <math>\beta</math>-blocker therapy.</li> </ul> </li> <li>○ Other anti-ischemic interventions <ul style="list-style-type: none"> <li>▪ Ranolazine is currently indicated for treatment of chronic angina; however, it may also improve outcomes in NSTEMI-ACS patients due to a reduction in recurrent ischemia.</li> </ul> </li> <li>○ Cholesterol management <ul style="list-style-type: none"> <li>▪ High-intensity statin therapy should be initiated or continued in all patients with NSTEMI-ACS and no contraindications to its use. Treatment with statins reduces the rate of recurrent MI, coronary heart disease</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>mortality, need for myocardial revascularization, and stroke.</p> <ul style="list-style-type: none"> <li>▪ It is reasonable to obtain a fasting lipid profile in patients with NSTEMI-ACS, preferably within 24 hours of presentation.</li> </ul> <ul style="list-style-type: none"> <li>• Inhibitors of renin-angiotensin-aldosterone system <ul style="list-style-type: none"> <li>○ ACE inhibitors should be started and continued indefinitely in all patients with LVEF &lt;0.40 and in those with hypertension, diabetes mellitus, or stable CKD, unless contraindicated.</li> <li>○ ARBs are recommended in patients with heart failure or myocardial infarction with LVEF &lt;0.40 who are ACE inhibitor intolerant.</li> <li>○ Aldosterone-blockade is recommended in patients post-MI without significant renal dysfunction (creatinine &gt;2.5 mg/dL in men or &gt;2.0 mg/dL in women) or hyperkalemia (K &gt;5.0 mEq/L) who are receiving therapeutic doses of ACE inhibitor and <math>\beta</math>-blocker and have a LVEF &lt;0.40, diabetes mellitus, or heart failure.</li> </ul> </li> <li>• Initial antiplatelet/anticoagulant therapy in patients with definite or likely NSTEMI-ACS treated with an initial invasive or ischemia-guided strategy <ul style="list-style-type: none"> <li>○ Non-enteric coated, chewable aspirin (162 to 325 mg) should be given to all patients with NSTEMI-ACS without contraindications as soon as possible after presentation, and a maintenance dose of aspirin (81 to 162 mg/day) should be continued indefinitely.</li> <li>○ In patients who are unable to take aspirin because of hypersensitivity or major gastrointestinal intolerance, a loading dose of clopidogrel followed by a daily maintenance dose should be administered.</li> <li>○ A P2Y<sub>12</sub> receptor inhibitor (clopidogrel or ticagrelor) in addition to aspirin should be administered for up to 12 months to all patients with NSTEMI-ACS without contraindications who are treated with an early invasive or ischemia-guided strategy. Options include: <ul style="list-style-type: none"> <li>▪ Clopidogrel: 300 or 600 mg loading dose, then 75 mg daily.</li> <li>▪ Ticagrelor: 180 mg loading dose, then 90 mg twice daily.</li> <li>▪ It is reasonable to use ticagrelor in preference to clopidogrel for P2Y<sub>12</sub> treatment in patients with NSTEMI-ACS who undergo an early invasive or ischemia-guided strategy.</li> <li>▪ In patients with NSTEMI-ACS treated with an early invasive strategy and dual antiplatelet therapy (DAPT) with intermediate/high-risk features (e.g., positive troponin), a GP IIb/IIIa inhibitor may be considered as part of initial antiplatelet therapy. Preferred options are eptifibatide or tirofiban.</li> </ul> </li> </ul> </li> </ul> <p><u>Percutaneous coronary intervention (PCI)- Antiplatelet and anticoagulant therapy</u></p> <ul style="list-style-type: none"> <li>• Antiplatelet agents <ul style="list-style-type: none"> <li>○ Patients already taking daily aspirin before PCI should take 81 to 325 mg non-enteric coated aspirin before PCI</li> <li>○ Patients not on aspirin therapy should be given non-enteric coated aspirin 325 mg as soon as possible before PCI.</li> <li>○ After PCI, aspirin should be continued indefinitely.</li> <li>○ A loading dose of a P2Y<sub>12</sub> inhibitor should be given before the procedure in patients undergoing PCI with stenting. Options include clopidogrel 600 mg, prasugrel 60 mg, or ticagrelor 180 mg.</li> <li>○ In patients with NSTEMI-ACS and high-risk features (e.g., elevated troponin) not adequately pretreated with clopidogrel or ticagrelor, it is useful to administer a GP IIb/IIIa inhibitor (abciximab, double-bolus eptifibatide, or high-dose bolus tirofiban) at the time of PCI.</li> <li>○ In patients receiving a stent (bare metal or drug eluting) during PCI, P2Y<sub>12</sub> inhibitor therapy should be given for at least 12 months. Options include clopidogrel 75 mg daily, prasugrel 10 mg daily, or ticagrelor 90 mg twice daily.</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Anticoagulant therapy               <ul style="list-style-type: none"> <li>○ An anticoagulant should be administered to patients with NSTEMI-ACS undergoing PCI to reduce the risk of intracoronary and catheter thrombus formation.</li> <li>○ Intravenous unfractionated heparin (UFH) is useful in patients with NSTEMI-ACS undergoing PCI.</li> <li>○ Bivalirudin is useful as an anticoagulant with or without prior treatment with UFH.</li> <li>○ An additional dose of 0.3 mg/kg intravenous enoxaparin should be administered at the time of PCI to patients with NSTEMI-ACS who have received fewer than two therapeutic subcutaneous doses or received the last subcutaneous enoxaparin dose eight to 12 hours before PCI.</li> <li>○ If PCI is performed while the patient is on fondaparinux, an additional 85 IU/kg of UFH should be given intravenously immediately before PCI because of the risk of catheter thrombosis (60 IU/kg IV if a GP IIb/IIIa inhibitor used with UFH dosing based on the target-activated clotting time).</li> <li>○ Anticoagulant therapy should be discontinued after PCI unless there is a compelling reason to continue.</li> </ul> </li> <li>• Timing of CABG in relation to use of antiplatelet agents               <ul style="list-style-type: none"> <li>○ Non-enteric coated aspirin (81 to 325 mg daily) should be administered preoperatively to patients undergoing CABG.</li> <li>○ In patients referred for elective CABG, clopidogrel and ticagrelor should be discontinued for at least five days before surgery and prasugrel for at least seven days before surgery.</li> <li>○ In patients referred for urgent CABG, clopidogrel and ticagrelor should be discontinued for at least 24 hours to reduce major bleeding.</li> <li>○ In patients referred for CABG, short-acting intravenous GP IIb/IIIa inhibitors (eptifibatid or tirofiban) should be discontinued for at least 2 to 4 hours before surgery and abciximab for at least 12 hours before to limit blood loss and transfusion.</li> </ul> </li> </ul> <p><u>Late hospital care, hospital discharge, and posthospital discharge care</u></p> <ul style="list-style-type: none"> <li>• Medications at discharge               <ul style="list-style-type: none"> <li>○ Medications required in the hospital to control ischemia should be continued after hospital discharge in patients with NSTEMI-ACS who do not undergo coronary revascularization, patients with incomplete or unsuccessful revascularization, and patients with recurrent symptoms after revascularization. Titration of the doses may be required.</li> <li>○ All patients who are post-NSTEMI-ACS should be given sublingual or spray nitroglycerin with verbal and written instructions for its use.</li> <li>○ Before hospital discharge, patients with NSTEMI-ACS should be informed about symptoms of worsening myocardial ischemia and MI and should be given verbal and written instructions about how and when to seek emergency care for such symptoms.</li> <li>○ Before hospital discharge, patients who are post-NSTEMI-ACS and/or designated responsible caregivers should be provided with easily understood and culturally sensitive verbal and written instructions about medication type, purpose, dose, frequency, side effects, and duration of use.</li> <li>○ For patients who are post-NSTEMI-ACS and have initial angina lasting more than one minute, nitroglycerin (one dose sublingual or spray) is recommended if angina does not subside within three to five minutes; call 9-1-1 immediately to access emergency medical services.</li> <li>○ If the pattern or severity of angina changes, suggesting worsening myocardial ischemia (e.g., pain is more frequent or severe or is precipitated by less effort or occurs at rest), patients should contact their clinician without delay to assess the need for additional treatment or testing.</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>○ Before discharge, patients should be educated about modification of cardiovascular risk factors.</li> <li>● Late hospital and post-hospital oral antiplatelet therapy               <ul style="list-style-type: none"> <li>○ Aspirin should be continued indefinitely. The dose should be 81 mg daily in patients treated with ticagrelor and 81 to 325 mg daily in all other patients.</li> <li>○ In addition to aspirin, a P2Y<sub>12</sub> inhibitor (either clopidogrel or ticagrelor) should be continued for up to 12 months in all patients with NSTEMI-ACS without contraindications who are treated with an ischemia-guided strategy.</li> <li>○ In patients receiving a stent (bare-metal stent or DES) during PCI for NSTEMI-ACS, P2Y<sub>12</sub> inhibitor therapy should be given for at least 12 months.</li> </ul> </li> <li>● Combined oral anticoagulant therapy and antiplatelet therapy in patients with NSTEMI-ACS               <ul style="list-style-type: none"> <li>○ The duration of triple antithrombotic therapy with a vitamin K antagonist, aspirin, and a P2Y<sub>12</sub> receptor inhibitor in patients with NSTEMI-ACS should be minimized to the extent possible to limit the risk of bleeding.</li> <li>○ Proton pump inhibitors should be prescribed in patients with NSTEMI-ACS with a history of gastrointestinal bleeding who require triple antithrombotic therapy with a vitamin K antagonist, aspirin, and a P2Y<sub>12</sub> receptor inhibitor.</li> </ul> </li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Management of Acute Coronary Syndromes in Patients Presenting without Persistent ST-Segment Elevation</b> (2020)<sup>19</sup></p>	<p><b>Pharmacological treatment of ischemia</b></p> <ul style="list-style-type: none"> <li>● Sublingual or intravenous nitrates and early initiation of β-blocker treatment is recommended in patients with ongoing ischemic symptoms and without contraindications.</li> <li>● Continuation of chronic β-blocker therapy is recommended unless the patient is in overt heart failure</li> <li>● Sublingual or intravenous nitrates are recommended to relieve angina; intravenous treatment is recommended in patients with recurrent angina, uncontrolled hypertension, or signs of heart failure.</li> <li>● In patients with suspected/confirmed vasospastic angina, calcium channel blockers, and nitrates should be considered and β-blockers avoided.</li> </ul> <p><b>Recommendations for platelet inhibition in non-ST-elevation acute coronary syndromes</b></p> <ul style="list-style-type: none"> <li>● Aspirin is recommended for all patients without contraindications at an initial oral loading dose of 150 to 300 mg (in aspirin-naïve patients) and a maintenance dose of 75 to 100 mg/day long-term regardless of treatment strategy.</li> <li>● A P2Y<sub>12</sub> inhibitor is recommended, in addition to aspirin, for 12 months unless there are contraindications such as excessive risks of bleeds.           <ul style="list-style-type: none"> <li>○ Ticagrelor (180 mg loading dose, 90 mg twice daily) is recommended, in the absence of contraindication, for all patients at moderate-to-high risk of ischemic events (e.g., elevated cardiac troponins), regardless of initial treatment strategy and including those pretreated with clopidogrel (which should be discontinued when ticagrelor is started).</li> <li>○ Prasugrel (60 mg loading dose, 10 mg daily dose) is recommended in patients who are proceeding to PCI if no contraindication. Prasugrel should be considered in preference to ticagrelor in NSTEMI-ACS patients who proceed to PCI.</li> <li>○ Clopidogrel (300 to 600 mg loading dose, 75 mg daily dose) is recommended for patients who cannot receive ticagrelor or prasugrel or who require oral anticoagulation.</li> </ul> </li> <li>● P2Y<sub>12</sub> inhibitor administration for a shorter duration of three to six months after DES implantation may be considered in patients deemed at high bleeding risk.</li> <li>● Pre-treatment with a P2Y<sub>12</sub> inhibitor may be considered in patients with NSTEMI-ACS who are not planned to undergo an early invasive strategy.</li> <li>● It is not recommended to administer routine pre-treatment with a P2Y<sub>12</sub> inhibitor in patients in whom coronary anatomy is not known.</li> <li>● It is not recommended to administer prasugrel in patients whom coronary anatomy</li> </ul>

Clinical Guideline	Recommendations
	<p>is not known.</p> <ul style="list-style-type: none"> <li>• GPIIb/IIIa inhibitors during PCI should be considered for bailout situations or thrombotic complications.</li> <li>• Cangrelor may be considered in P2Y<sub>12</sub> inhibitor-naïve patients undergoing PCI.</li> <li>• It is not recommended to administer GPIIb/IIIa inhibitors in patients whom coronary anatomy is not known.</li> <li>• P2Y<sub>12</sub> inhibitor administration in addition to aspirin beyond one year may be considered after careful assessment of the ischemic and bleeding risks of the patient.</li> </ul> <p><u>Recommendations for anticoagulation in non-ST-elevation acute coronary syndromes</u></p> <ul style="list-style-type: none"> <li>• Parenteral anticoagulation is recommended at the time of diagnosis according to both ischemic and bleeding risks.</li> <li>• Fondaparinux is recommended as having the most favorable efficacy-safety profile regardless of the management strategy.</li> <li>• Bivalirudin is recommended as an alternative to UFH plus GPIIb/IIIa inhibitors during PCI.</li> <li>• UFH is recommended in patients undergoing PCI who did not receive any anticoagulant.</li> <li>• In patients on fondaparinux undergoing PCI, a single intravenous bolus of UFH is recommended during the procedure.</li> <li>• Enoxaparin or UFH are recommended when fondaparinux is not available.</li> <li>• Enoxaparin should be considered as an anticoagulant for PCI in patients pretreated for PCI with subcutaneous enoxaparin.</li> <li>• Additional activated clotting time-guided intravenous boluses of UFH during PCI may be considered following initial UFH treatment.</li> <li>• Discontinuation of anticoagulation should be considered after PCI, unless otherwise indicated.</li> <li>• Crossover between UFH and LMWH is not recommended.</li> <li>• In NSTEMI patients with no prior stroke/TIA and at high ischemic risk as well as low bleeding risk receiving aspirin and clopidogrel, low-dose rivaroxaban (2.5 mg twice daily for approximately one year) may be considered after discontinuation of parenteral anticoagulation.</li> </ul> <p><u>Recommendations for combining antiplatelet agents and anticoagulants in non-ST-elevation acute coronary syndrome patients requiring chronic oral anticoagulation</u></p> <ul style="list-style-type: none"> <li>• In patients with a firm indication for oral anticoagulation (e.g., atrial fibrillation with a CHADS<sub>2</sub>-VASc score <math>\geq 2</math>, recent VTE, mechanical valve prosthesis), oral anticoagulation is recommended in addition to antiplatelet therapy.</li> <li>• An early invasive coronary angiography (within 24 hours) should be considered in moderate- to high-risk patients, irrespective of oral anticoagulant exposure, to expedite treatment allocation (medical vs PCI vs CABG) and to determine optimal antithrombotic regimen.</li> <li>• Initial dual antiplatelet therapy with aspirin plus a P2Y<sub>12</sub> inhibitor in addition to oral anticoagulation before coronary angiography is not recommended.</li> <li>• During PCI, additional parenteral anticoagulation is recommended, irrespective of the timing of the last dose of all non-vitamin K antagonist oral anticoagulants (NOACs) and if INR is <math>&lt; 2.5</math> in VKA-treated patients.</li> <li>• Uninterrupted therapeutic anticoagulation with VKA or NOACs should be considered during the periprocedural phase.</li> <li>• Periprocedural DAPT administration consisting of aspirin and clopidogrel up to one week is recommended</li> <li>• Discontinuation of antiplatelet treatment in patients treated with an oral anticoagulant is recommended after 12 months</li> <li>• Following coronary stenting, dual (oral) antiplatelet therapy (DAPT) including new</li> </ul>

Clinical Guideline	Recommendations
	<p>P2Y<sub>12</sub> inhibitors should be considered as an alternative to triple therapy for patients with non-ST-elevation acute coronary syndromes and atrial fibrillation with a CHADS<sub>2</sub>-VASc score of 1 (in males) or 2 (in females).</p> <ul style="list-style-type: none"> <li>• If at low bleeding risk (HAS-BLED ≤2), triple therapy with oral anticoagulant, aspirin, and clopidogrel should be considered for six months, followed by oral anticoagulant and aspirin or clopidogrel continued up to 12 months.</li> <li>• If at high bleeding risk (HAS-BLED ≥3), triple therapy with oral anticoagulant, aspirin, and clopidogrel should be considered for one month, followed by oral anticoagulant and aspirin or clopidogrel continued up to 12 months irrespective of the stent type.</li> <li>• Dual therapy with oral anticoagulant and clopidogrel may be considered as an alternative to triple antithrombotic therapy in selected patients (HAS-BLED ≥3 and low risk of stent thrombosis).</li> <li>• The use of ticagrelor or prasugrel as part of triple therapy is not recommended.</li> <li>• In medically managed patients, one antiplatelet agent in addition to oral anticoagulant should be considered for up to one year.</li> </ul> <p><u>Recommendations for post-interventional and maintenance treatment</u></p> <ul style="list-style-type: none"> <li>• In patients with NSTEMI-ACS with coronary stent implantation, DAPT with a P2Y<sub>12</sub> inhibitor on top of aspirin is recommended for 12 months unless there are contraindications such as excessive risk of bleeding.</li> <li>• Adding a second anti-thrombotic agent to aspirin for extended long-term secondary prevention should be considered in patients with a moderate to high risk of ischemic events and without increased risk of major bleeding.</li> <li>• After stent implantation with high risk of bleeding, discontinuation of P2Y<sub>12</sub> inhibitor therapy after three months should be considered</li> <li>• After stent implantation in patients undergoing DAPT, stopping aspirin after three to six months should be considered, depending on balance between ischemic and bleeding risk.</li> <li>• De-escalation of P2Y<sub>12</sub> inhibitor treatment may be considered as an alternative DAPT strategy, especially for ACS patients deemed unsuitable for potent platelet inhibition.</li> </ul>
<p>American College of Cardiology/ American Heart Association: <b>Guideline for the Management of ST-Elevation Myocardial Infarction (2013)</b><sup>20</sup></p>	<p><u>Routine medical therapies: calcium channel blockers</u></p> <ul style="list-style-type: none"> <li>• Evidence demonstrates that beneficial effect on infarct size or the rate of reinfarction when calcium channel blocker therapy was initiated during either the acute or convalescent phase of ST-segment elevation myocardial infarction (STEMI). However, calcium channel blockers may be useful to relieve ischemia, lower blood pressure, or control the ventricular response rate to atrial fibrillation in patients who are intolerant to β-blockers.</li> <li>• Use of immediate-release nifedipine is contraindicated in patients with STEMI due to hypotension and reflex sympathetic activation with tachycardia.</li> </ul> <p><u>Routine medical therapies: β-blockers</u></p> <ul style="list-style-type: none"> <li>• Oral β-blockers should be initiated within the first 24 hours in patients with an ST-segment elevation myocardial infarction (STEMI) who do not have any of the following: 1) signs of heart failure, 2) evidence of a low-output state, 3) increased risk of cardiogenic shock, 4) other contraindications to use of oral β-blockers (e.g., PR interval &gt;24 seconds, second or third degree heart block, active asthma, reactive airway disease).</li> <li>• β-blockers should be continued during and after hospitalization for all patients with STEMI and with no contraindications to their use.</li> <li>• Patients with initial contraindications to the use of β-blockers in the first 24 hours after STEMI should be re-evaluated to determine their subsequent eligibility.</li> <li>• It is reasonable to administer intravenous β-blockers at the time of presentation to patients with STEMI and no contraindications to their use who are hypertensive or</li> </ul>

Clinical Guideline	Recommendations
	<p>have ongoing ischemia.</p> <p><u>Routine medical therapies: Renin-Angiotensin-Aldosterone System Inhibitors</u></p> <ul style="list-style-type: none"> <li>• An angiotensin-converting enzyme (ACE) inhibitor should be administered within the first 24 hours to all patients with STEMI with anterior location, HF, or ejection fraction (EF) <math>\leq 40\%</math>, unless contraindicated.</li> <li>• An angiotensin receptor blocker (ARB) should be given to patients with STEMI who have indications for but are intolerant of ACE inhibitors.</li> <li>• An aldosterone antagonist should be given to patients with STEMI and no contraindications who are already receiving an ACE inhibitor and <math>\beta</math>-blocker and who have an EF <math>\leq 40\%</math> and either symptomatic heart failure or diabetes.</li> </ul> <p><u>Routine medical therapies: Lipid management</u></p> <ul style="list-style-type: none"> <li>• High-intensity statin therapy should be initiated or continued in all patients with STEMI and no contraindications to its use.</li> <li>• It is reasonable to obtain a fasting lipid profile in patients with STEMI, preferably within 24 hours of presentation.</li> </ul>
<p>European Society of Cardiology: <b>Management of Acute Myocardial Infarction in Patients Presenting with ST-segment Elevation (2017)</b><sup>21</sup></p>	<p><u>Routine therapies in the acute, subacute and long term phase of ST-elevation myocardial infarction (STEMI)</u></p> <ul style="list-style-type: none"> <li>• Antiplatelet therapy with low dose aspirin (75 to 100 mg) is indicated indefinitely after STEMI.</li> <li>• Dual antiplatelet therapy with a combination of aspirin and prasugrel or aspirin and ticagrelor is recommended for 12 months after percutaneous coronary intervention (PCI), unless there are contraindications such as excessive risk of bleeding.</li> <li>• A proton pump inhibitor (PPI) in combination with dual antiplatelet therapy is recommended in patients at high risk of gastrointestinal bleeding.</li> <li>• In patients with an indication for oral anticoagulation, oral anticoagulants are indicated in addition to antiplatelet therapy.</li> <li>• In patients who are at high risk of severe bleeding complications, discontinuation of P2Y<sub>12</sub> inhibitor therapy after six months should be considered.</li> <li>• In STEMI patients with stent implantation and an indication for oral anticoagulation, triple therapy (oral anticoagulant, aspirin, and clopidogrel) should be considered for one to six months (according a balance between the estimated risk of recurrent coronary events and bleeding).</li> <li>• In patients with left ventricular thrombus, anticoagulation should be instituted for a minimum of six months, guided by repeated imaging.</li> <li>• In selected patients who receive aspirin and clopidogrel, low-dose rivaroxaban (2.5 mg twice daily) may be considered if the patient is at low bleeding risk.</li> <li>• Dual antiplatelet therapy should be used up to one year in patients with STEMI who did not receive a stent unless there are contraindications such as excessive risk of bleeding.</li> <li>• In high ischemic-risk patients (age <math>\geq 50</math> years, and at least one of the following risk factors: age <math>\geq 65</math> years, diabetes mellitus on medication, prior spontaneous MAI, multivessel CAD, or chronic renal dysfunction with eGFR <math>&lt; 60</math> mL/min) who have tolerated dual antiplatelet therapy without a bleeding complication, treatment with dual antiplatelet therapy in the form of ticagrelor 60 mg twice a day on top of aspirin for longer than 12 months may be considered for up to three years.</li> <li>• The use of ticagrelor or prasugrel is not recommended as part of triple antithrombotic therapy with aspirin and oral anticoagulation.</li> <li>• Oral treatment with <math>\beta</math>-blockers should be considered during hospital stay and continued thereafter in all patients without contraindications.</li> <li>• Oral treatment with <math>\beta</math>-blockers is indicated in patients with heart failure or left ventricular dysfunction, LVEF <math>\leq 40\%</math> unless contraindicated.</li> <li>• Intravenous <math>\beta</math>-blockers must be avoided in patients with hypotension or acute heart failure or AV block or severe bradycardia.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Intravenous <math>\beta</math>-blockers should be considered at the time of presentation in patients undergoing primary PCI without contraindications, with high blood pressure, tachycardia, and no signs of heart failure.</li> <li>• A fasting lipid profile must be obtained in all STEMI patients, as soon as possible after presentation.</li> <li>• It is recommended to initiate or continue high dose statins early after admission in all STEMI patients without contraindication or history of intolerance, regardless of initial cholesterol values and maintain it long-term.</li> <li>• An LDL-C goal of <math>&lt;1.8</math> mmol/L (70 mg/dL) or a reduction of at least 50% if the baseline LDL-C is between 1.8 to 3.5 mmol/L (70 to 135 mg/dL) is recommended.</li> <li>• In patients with LDL-C <math>&gt;1.8</math> mmol/L (<math>&gt;70</math> mg/dL) despite a maximally tolerated statin dose who remain at high risk, further therapy to reduce LDL-C should be considered.</li> <li>• ACE inhibitors are indicated starting within the first 24 hours of STEMI in patients with evidence of heart failure, LV systolic dysfunction, diabetes or an anterior infarct.</li> <li>• An ARB, preferably valsartan, is an alternative to ACE inhibitors in patients with heart failure or LV systolic dysfunction, particularly those who are intolerant to ACE inhibitors.</li> <li>• ACE inhibitors should be considered in all patients in the absence of contraindications.</li> <li>• Aldosterone antagonists, e.g. eplerenone, are indicated in patients with an ejection fraction <math>\leq 40\%</math> and heart failure or diabetes, provided no renal failure or hyperkalemia.</li> </ul>
<p>American College of Cardiology/ American Heart Association: <b>Guideline on the Primary Prevention of Cardiovascular Disease (2019)</b><sup>22</sup></p>	<p><u>Top 10 messages for the primary prevention of cardiovascular disease</u></p> <ul style="list-style-type: none"> <li>• The most important way to prevent atherosclerotic vascular disease, heart failure, and atrial fibrillation is to promote a healthy lifestyle throughout life.</li> <li>• A team-based care approach is an effective strategy for the prevention of cardiovascular disease. Clinicians should evaluate the social determinants of health that affect individuals to inform treatment decisions.</li> <li>• Adults who are 40 to 75 years of age and are being evaluated for cardiovascular disease prevention should undergo 10-year atherosclerotic cardiovascular disease (ASCVD) risk estimation and have a clinician–patient risk discussion before starting on pharmacological therapy, such as antihypertensive therapy, a statin, or aspirin. In addition, assessing for other risk-enhancing factors can help guide decisions about preventive interventions in select individuals, as can coronary artery calcium scanning.</li> <li>• All adults should consume a healthy diet that emphasizes the intake of vegetables, fruits, nuts, whole grains, lean vegetable or animal protein, and fish and minimizes the intake of trans fats, processed meats, refined carbohydrates, and sweetened beverages. For adults with overweight and obesity, counseling and caloric restriction are recommended for achieving and maintaining weight loss.</li> <li>• Adults should engage in at least 150 minutes per week of accumulated moderate-intensity physical activity or 75 minutes per week of vigorous-intensity physical activity.</li> <li>• For adults with type 2 diabetes mellitus, lifestyle changes, such as improving dietary habits and achieving exercise recommendations, are crucial. If medication is indicated, metformin is first-line therapy, followed by consideration of a sodium-glucose cotransporter 2 inhibitor or a glucagon-like peptide-1 receptor agonist.</li> <li>• All adults should be assessed at every healthcare visit for tobacco use, and those who use tobacco should be assisted and strongly advised to quit.</li> <li>• Aspirin should be used infrequently in the routine primary prevention of ASCVD because of lack of net benefit.</li> <li>• Statin therapy is first-line treatment for primary prevention of ASCVD in patients with elevated low-density lipoprotein cholesterol levels (<math>\geq 190</math> mg/dL), those with</li> </ul>

Clinical Guideline	Recommendations
	<p>diabetes mellitus, who are 40 to 75 years of age, and those determined to be at sufficient ASCVD risk after a clinician–patient risk discussion.</p> <ul style="list-style-type: none"> <li>• Nonpharmacological interventions are recommended for all adults with elevated blood pressure or hypertension. For those requiring pharmacological therapy, the target blood pressure should generally be &lt;130/80 mm Hg.</li> </ul> <p><u>Adults with Type 2 Diabetes Mellitus</u></p> <ul style="list-style-type: none"> <li>• For all adults with T2DM, a tailored nutrition plan focusing on a heart-healthy dietary pattern is recommended to improve glycemic control, achieve weight loss if needed, and improve other ASCVD risk factors.</li> <li>• Adults with T2DM should perform at least 150 minutes per week of moderate-intensity physical activity or 75 minutes of vigorous-intensity physical activity to improve glycemic control, achieve weight loss if needed, and improve other ASCVD risk factors.</li> <li>• For adults with T2DM, it is reasonable to initiate metformin as first-line therapy along with lifestyle therapies at the time of diagnosis to improve glycemic control and reduce ASCVD risk.</li> <li>• For adults with T2DM and additional ASCVD risk factors who require glucose-lowering therapy despite initial lifestyle modifications and metformin, it may be reasonable to initiate a sodium-glucose cotransporter 2 (SGLT-2) inhibitor or a glucagon-like peptide-1 receptor (GLP-1R) agonist to improve glycemic control and reduce CVD risk.</li> </ul> <p><u>Adults with high blood cholesterol</u></p> <ul style="list-style-type: none"> <li>• In adults at intermediate risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk), statin therapy reduces risk of ASCVD, and in the context of a risk discussion, if a decision is made for statin therapy, a moderate-intensity statin should be recommended.</li> <li>• In intermediate risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk) patients, LDL-C levels should be reduced by 30% or more, and for optimal ASCVD risk reduction, especially in patients at high risk (<math>\geq 20\%</math> 10-year ASCVD risk), levels should be reduced by 50% or more.</li> <li>• In adults 40 to 75 years of age with diabetes, regardless of estimated 10-year ASCVD risk, moderate-intensity statin therapy is indicated.</li> <li>• In patients 20 to 75 years of age with an LDL-C level of 190 mg/dL (<math>\geq 4.9</math> mmol/L) or higher, maximally tolerated statin therapy is recommended.</li> <li>• In adults with diabetes mellitus who have multiple ASCVD risk factors, it is reasonable to prescribe high-intensity statin therapy with the aim to reduce LDL-C levels by 50% or more.</li> <li>• In intermediate-risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk) adults, risk-enhancing factors favor initiation or intensification of statin therapy.</li> <li>• In intermediate-risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk) adults or selected borderline-risk (5% to <math>&lt; 7.5\%</math> 10-year ASCVD risk) adults in whom a coronary artery calcium score is measured for the purpose of making a treatment decision, AND             <ul style="list-style-type: none"> <li>○ If the coronary artery calcium score is zero, it is reasonable to withhold statin therapy and reassess in five to 10 years, as long as higher-risk conditions are absent (e.g., diabetes, family history of premature CHD, cigarette smoking);</li> <li>○ If coronary artery calcium score is one to 99, it is reasonable to initiate statin therapy for patients <math>\geq 55</math> years of age;</li> <li>○ If coronary artery calcium score is 100 or higher or in the 75th percentile or higher, it is reasonable to initiate statin therapy.</li> </ul> </li> <li>• In patients at borderline risk (5% to <math>&lt; 7.5\%</math> 10-year ASCVD risk), in risk discussion, the presence of risk-enhancing factors may justify initiation of moderate-intensity statin therapy.</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Adults with high blood pressure or hypertension</u></p> <ul style="list-style-type: none"> <li>• In adults with elevated blood pressure (BP) or hypertension, including those requiring antihypertensive medications nonpharmacological interventions are recommended to reduce BP. These include:               <ul style="list-style-type: none"> <li>○ weight loss;</li> <li>○ a heart-healthy dietary pattern;</li> <li>○ sodium reduction;</li> <li>○ dietary potassium supplementation;</li> <li>○ increased physical activity with a structured exercise program; and</li> <li>○ limited alcohol.</li> </ul> </li> <li>• In adults with an estimated 10-year ASCVD risk (ACC/AHA pooled cohort equations to estimate 10-year risk of ASCVD) of 10% or higher and an average systolic BP (SBP) of 130 mm Hg or higher or an average diastolic BP (DBP) of 80 mm Hg or higher, use of BP-lowering medications is recommended for primary prevention of CVD.</li> <li>• In adults with confirmed hypertension and a 10-year ASCVD event risk of 10% or higher, a BP target of less than 130/80 mm Hg is recommended.</li> <li>• In adults with hypertension and chronic kidney disease, treatment to a BP goal of less than 130/80 mm Hg is recommended.</li> <li>• In adults with T2DM and hypertension, antihypertensive drug treatment should be initiated at a BP of 130/80 mm Hg or higher, with a treatment goal of less than 130/80 mm Hg.</li> <li>• In adults with an estimated 10-year ASCVD risk &lt;10% and an SBP of 140 mm Hg or higher or a DBP of 90 mm Hg or higher, initiation and use of BP-lowering medication are recommended.</li> <li>• In adults with confirmed hypertension without additional markers of increased ASCVD risk, a BP target of less than 130/80 mm Hg may be reasonable.</li> </ul> <p><u>Recommendations for treatment of tobacco use</u></p> <ul style="list-style-type: none"> <li>• All adults should be assessed at every healthcare visit for tobacco use and their tobacco use status recorded as a vital sign to facilitate tobacco cessation.</li> <li>• To achieve tobacco abstinence, all adults who use tobacco should be firmly advised to quit.</li> <li>• In adults who use tobacco, a combination of behavioral interventions plus pharmacotherapy is recommended to maximize quit rates.</li> <li>• In adults who use tobacco, tobacco abstinence is recommended to reduce ASCVD risk.</li> <li>• To facilitate tobacco cessation, it is reasonable to dedicate trained staff to tobacco treatment in every healthcare system.</li> <li>• All adults and adolescents should avoid secondhand smoke exposure to reduce ASCVD risk.</li> </ul> <p><u>Recommendations for aspirin use</u></p> <ul style="list-style-type: none"> <li>• Low-dose aspirin (75 to 100 mg orally daily) might be considered for the primary prevention of ASCVD among select adults 40 to 70 years of age who are at higher ASCVD risk but not at increased bleeding risk.</li> <li>• Low-dose aspirin (75 to 100 mg orally daily) should not be administered on a routine basis for the primary prevention of ASCVD among adults &gt;70 years of age.</li> <li>• Low-dose aspirin (75 to 100 mg orally daily) should not be administered for the primary prevention of ASCVD among adults of any age who are at increased risk of bleeding.</li> </ul>
<p>American Heart Association/Americ</p>	<p><u>Treatment of Stage A heart failure (HF)</u></p> <ul style="list-style-type: none"> <li>• Hypertension should be controlled in accordance with guideline-directed</li> </ul>

Clinical Guideline	Recommendations
<p>an College of Cardiology/Heart Failure Society of America: <b>2022 AHA/ACC/HFSA Guideline for the Management of Heart Failure (2022)</b><sup>23</sup></p>	<p>medication therapy for hypertension to prevent symptomatic HF. (LoE: A)</p> <ul style="list-style-type: none"> <li>• In patients with type 2 diabetes and either established CVD or at high cardiovascular risk, SGLT-2 inhibitors should be used to prevent hospitalizations for HF. (LoE: A)</li> <li>• In the general population, healthy lifestyle habits such as regular physical activity, maintaining normal weight, healthy dietary patterns, and avoiding smoking are helpful to reduce future risk of HF. (LoE: B)</li> <li>• Patients at risk of developing HF, natriuretic peptide biomarker-based screening followed by team-based care, including a cardiovascular specialist optimizing therapy, can be useful to prevent the development of LV dysfunction (systolic or diastolic) or new-onset HF. (LoE: B)</li> </ul> <p><u>Treatment of Stage B heart failure</u></p> <ul style="list-style-type: none"> <li>• In patients with LVEF≤40%, ACE inhibitors should be used to prevent HF and reduce mortality. (LoE: A)</li> <li>• In patients with a recent or remote history of MI or ACS, statins should be used to prevent symptomatic HF and adverse cardiovascular events. (LoE: A)</li> <li>• In patients with a recent MI and LVEF≤40% who are intolerant to ACE inhibitors, ARB should be used to prevent symptomatic HF and reduce mortality. (LoE: B)</li> <li>• In patients with a recent or remote history of MI or ACS and LVEF≤40%, evidence-based beta blockers should be used to reduce mortality. (LoE: B)</li> <li>• In patients who are at least 40 days post-MI with LVEF ≤30% and NYHA class I symptoms while receiving guideline-directed medication therapy and have reasonable expectation of meaningful survival for greater than one year, an implantable cardioverter-defibrillator is recommended for primary prevention of sudden cardiac death to reduce total mortality. (LoE: B)</li> <li>• In patients with LVEF ≤40%, beta blockers should be used to prevent symptomatic HF. (LoE: C)</li> <li>• In patients with LVEF ≤50%, thiazolidinediones should not be used because they increase the risk of HF, including hospitalizations. (LoE: B)</li> <li>• In patients with LVEF ≤50%, nondihydropyridine calcium channel blockers with negative inotropic effects may be harmful. (LoE: C)</li> </ul> <p><u>Treatment for Stage C Heart Failure with Reduced Ejection Fraction (HFrEF)</u></p> <ul style="list-style-type: none"> <li>• For patients with stage C HF, avoiding excessive sodium intake is reasonable to reduce congestive symptoms. (LoE: C)</li> <li>• In patients with HF who have fluid retention, diuretics are recommended to relieve congestion, improve symptoms, and prevent worsening HF. (LoE: B)</li> <li>• For patients with HF and congestive symptoms, addition of a thiazide (e.g., metolazone) to treatment with a loop diuretic should be reserved for patients who do not respond to moderate or high dose loop diuretics to minimize electrolyte abnormalities. (LoE: B)</li> <li>• In patients with HFrEF and NYHA class II to III symptoms, the use of an ARNI is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, the use of an ACE inhibitor is beneficial to reduce morbidity and mortality when the use of an ARNI is not feasible. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, who are intolerant to an ACE inhibitor because of cough or angioedema, and when the use of an ARNI is not feasible, the use of an ARB is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with chronic symptomatic HFrEF NYHA class II or III who tolerate an ACE inhibitor or ARB, replacement by an ARNI is recommended to further reduce morbidity and mortality. (LoE: B)</li> <li>• ARNIs should not be administered concomitantly with ACE inhibitors or within 36</li> </ul>

Clinical Guideline	Recommendations
	<p>hours of the last dose of an ACE inhibitor. (LoE: B)</p> <ul style="list-style-type: none"> <li>• ARNI or ACE inhibitors should not be administered in patients with a history of angioedema. (LoE: C)</li> <li>• In patients with HFrEF, with current or previous symptoms, use of one of the three <math>\beta</math>-blockers proven to reduce mortality (e.g., bisoprolol, carvedilol, sustained-release metoprolol succinate) is recommended to reduce mortality and hospitalizations. (LoE: A)</li> <li>• In patients with HFrEF and NYHA class II to IV symptoms, a mineralocorticoid receptor antagonist (spironolactone or eplerenone) is recommended to reduce morbidity and mortality, if eGFR is <math>&gt;30</math> mL/min/1.73 m<sup>2</sup> and serum potassium is <math>&lt;5.0</math> mEq/L. Careful monitoring of potassium, renal function, and diuretic dosing should be performed at initiation and closely followed thereafter to minimize risk of hyperkalemia and renal insufficiency. (LoE: A)</li> <li>• In patients taking a mineralocorticoid receptor antagonist whose serum potassium cannot be maintained at <math>&lt;5.5</math> mEq/L, mineralocorticoid receptor antagonist should be discontinued to avoid life threatening hyperkalemia. (LoE: B)</li> <li>• In patients with symptomatic chronic HFrEF, SGLT-2 an inhibitor is recommended to reduce hospitalization for HF and cardiovascular mortality, irrespective of the presence of type 2 diabetes. (LoE: A)</li> <li>• The combination of hydralazine and isosorbide dinitrate is recommended to improve symptoms and reduce morbidity and mortality for patients self-identified as African Americans with NYHA class III to IV HFrEF receiving optimal therapy. (LoE: A)</li> <li>• In patients with current or previous symptomatic HFrEF who cannot be given first-line agents, such as an ARNI, ACE inhibitor or ARB because of drug intolerance or renal insufficiency, a combination of hydralazine and isosorbide dinitrate might be considered to reduce morbidity and mortality. (LoE: C)</li> <li>• In patients with HF class II to IV symptoms, omega-3 polyunsaturated fatty acid supplementation may be reasonable to use as adjunctive therapy to reduce mortality and cardiovascular hospitalizations. (LoE: B)</li> <li>• In patients with chronic HFrEF without specific indication (e.g., venous thromboembolism, atrial fibrillation, a previous thromboembolic event, or a cardioembolic source, anticoagulation is not recommended. (LoE: B)</li> <li>• Dihydropyridine and non-dihydropyridine calcium channel blockers are not recommended for patients with HFrEF. (LoE: A)</li> <li>• In patients with HFrEF, vitamins, nutritional supplements, and hormonal therapy are not recommended other than to correct specific deficiencies. (LoE: B)</li> <li>• In patients with HFrEF, class IC antiarrhythmic medication and dronedarone may increase risk of mortality. (LoE: A)</li> <li>• In patients with HFrEF, thiazolidinediones increase the risk of worsening HF symptoms and hospitalizations. (LoE: A)</li> <li>• In patients with type 2 diabetes and high cardiovascular risk, the DPP-4 inhibitors, saxagliptin and alogliptin, increase the risk of HF hospitalization and should be avoided in patients with HF. (LoE: B)</li> <li>• In patients with HFrEF, nonsteroidal anti-inflammatory drugs worsen HF symptoms and should be avoided or withdrawn whenever possible. (LoE: B)</li> <li>• For patients with symptomatic (NYHA class II to III) stable chronic HFrEF (LVEF <math>\leq 35\%</math>) who are receiving guideline-directed medical therapy, including a maximally tolerated dose of a beta blocker, and who are in sinus rhythm with a heart rate of <math>\geq 70</math> beats per minute at rest, ivabradine can be beneficial to reduce HF hospitalizations and cardiovascular death. (LoE: B)</li> <li>• In patients with symptomatic HFrEF despite guideline-directed medical therapy or who are unable to tolerate guideline-directed medical therapy, digoxin might be considered to decrease hospitalizations for HF. (LoE: B)</li> <li>• In select high-risk patients with HFrEF and recent worsening of HF already on</li> </ul>

Clinical Guideline	Recommendations
	<p>guideline-directed medical therapy, an oral soluble guanylate cyclase stimulator (vericiguat) may be considered to reduce HF hospitalization and cardiovascular death. (LoE: B)</p> <p><b>Pharmacological treatment for Stage C HF with mildly reduced EF and improved EF</b></p> <ul style="list-style-type: none"> <li>• In patients with HF with mildly reduced EF, SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• Among patients with current or previous symptomatic HF with mildly reduced EF (LVEF, 41 to 49%), use of evidence-based beta blockers for HFrEF, ARNI, ACE inhibitor or ARB, and mineralocorticoid receptor antagonists may be considered to reduce the risk of HF hospitalization and cardiovascular mortality, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• In patients with HF with improved EF after treatment, guideline-directed medical therapy should be continued to prevent relapse of HF and LV dysfunction, even in patients who may become asymptomatic. (LoE: B)</li> </ul> <p><b>Pharmacological treatment for Stage C HF with preserved EF (HFpEF)</b></p> <ul style="list-style-type: none"> <li>• Patients with hypertension and HFpEF should have medication titrated to attain blood pressure targets in accordance with published clinical practice guidelines to prevent morbidity. (LoE: C)</li> <li>• SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• In patients with HFpEF, the use of a mineralocorticoid receptor antagonist, ARB, or ARNI may be considered to decrease hospitalizations, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• Routine use of nitrates or phosphodiesterase-5 inhibitors to increase activity or quality of life in patients with HFpEF is ineffective. (LoE: B)</li> </ul> <p><b>Treatment of Stage D (advanced/refractory) HF</b></p> <ul style="list-style-type: none"> <li>• For patients with advanced HF and hyponatremia, the benefit of fluid restriction to reduce congestive symptoms is uncertain. (LoE: C)</li> <li>• Continuous intravenous inotropic support is reasonable as “bridge therapy” in patients with HF (Stage D) refractory to guideline-directed medical therapy and device therapy who are eligible for and awaiting mechanical circulatory support or cardiac transplantation. (LoE: B)</li> <li>• In select patients with HF Stage D, despite optimal guideline-directed medical therapy and device therapy who are ineligible for either mechanical circulatory support or cardiac transplantation, continuous intravenous inotropic support may be considered as palliative therapy for symptom control and improvement in functional status. (LoE: B)</li> <li>• Long-term use of either continuous or intermittent, intravenous inotropic agents, for reasons other than palliative care or as a bridge to advanced therapies, is potentially harmful. (LoE: B)</li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure (2021)</b><sup>24</sup></p>	<p><b>Pharmacological treatments indicated in patients with (NYHA Class II-IV) heart failure with reduced ejection fraction</b></p> <ul style="list-style-type: none"> <li>• An ACE inhibitor is recommended, in addition to a <math>\beta</math>-blocker, for symptomatic patients with HFrEF to reduce the risk of HF hospitalization and death.</li> <li>• A mineralocorticoid receptor antagonist (MRA) is recommended for patients with HFrEF, who remain symptomatic despite treatment with an ACE inhibitor and a <math>\beta</math>-blocker, to reduce the risk of HF hospitalization and death.</li> <li>• Dapagliflozin or empagliflozin are recommended for patients with HFrEF to reduce the risk of HF hospitalization and death. Dapagliflozin or empagliflozin are recommended, in addition to optimal medical therapy with an ACE-I/ARNI, a <math>\beta</math>-blocker and an MRA, for patients with HFrEF regardless of diabetes status.</li> <li>• Sacubitril-valsartan is recommended as a replacement for an ACE inhibitor to</li> </ul>

Clinical Guideline	Recommendations
	<p>further reduce the risk of HF hospitalization and death in ambulatory patients with HFrEF who remain symptomatic despite optimal treatment with an ACE inhibitor, a <math>\beta</math>-blocker, and a mineralocorticoid receptor antagonist.</p> <ul style="list-style-type: none"> <li>• Diuretics are recommended in order to improve symptoms and exercise capacity in patients with signs and/or symptoms of congestion.</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization or cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm despite treatment with an evidence-based dose of <math>\beta</math>-blocker (or maximum tolerated dose below that), ACE inhibitor (or ARB), and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm who are unable to tolerate or have contraindications for a <math>\beta</math>-blocker. Patients should also receive an ACE inhibitor (or ARB) and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• An ARB is recommended to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients unable to tolerate an ACE inhibitor (patients should also receive a <math>\beta</math>-blocker and mineralocorticoid receptor antagonist).</li> <li>• An ARB may be considered to reduce the risk of HF hospitalization and death in patients who are symptomatic despite treatment with a <math>\beta</math>-blocker who are unable to tolerate a mineralocorticoid receptor antagonist.</li> <li>• Vericiguat may be considered in patients in NYHA class II-IV who have had worsening HF despite treatment with an ACE-I (or ARNI), a <math>\beta</math>-blocker and an MRA to reduce the risk of CV mortality or HF hospitalization.</li> <li>• Hydralazine and isosorbide dinitrate should be considered in self-identified black patients with LVEF <math>\leq 35\%</math> or with an LVEF <math>&lt; 45\%</math> combined with a dilated LV in NYHA Class III-IV despite treatment with an ACE-I a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist to reduce the risk of HF hospitalization and death.</li> <li>• Hydralazine and isosorbide dinitrate may be considered in symptomatic patients with HFrEF who can tolerate neither an ACE inhibitor nor an ARB (or they are contraindicated) to reduce the risk of death.</li> <li>• Digoxin is a treatment with less-certain benefits and may be considered in symptomatic patients in sinus rhythm despite treatment with an ACE inhibitor (or ARB), a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist, to reduce the risk of hospitalization (both all-cause and HF-hospitalizations).</li> </ul> <p><u>Recommendations for treatment of patients with (NYHA class II-IV) heart failure with mildly reduced ejection fraction (HFmrEF)</u></p> <ul style="list-style-type: none"> <li>• Diuretics are recommended in patients with congestion and HFmrEF in order to alleviate symptoms and signs.</li> <li>• An ACE inhibitor may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An ARB may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• A <math>\beta</math>-blocker may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An MRA may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• Sacubitril/valsartan may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> </ul> <p><u>Recommendations for treatment of patients with heart failure with preserved ejection fraction (HFpEF)</u></p>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• It is recommended to screen patients with HFpEF for both cardiovascular and noncardiovascular comorbidities, which, if present, should be treated provided safe and effective interventions exist to improve symptoms, well-being and/or prognosis.</li> <li>• Diuretics are recommended in congested patients with HFpEF in order to alleviate symptoms and signs.</li> </ul> <p><u>Recommendations for the primary prevention of heart failure in patients with risk factors for its development</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension is recommended to prevent or delay the onset of HF and prolong life.</li> <li>• Treatment with statins is recommended in patients at high risk of CV disease or with CV disease in order to prevent or delay the onset of HF, and to prevent HF hospitalizations.</li> <li>• SGLT2 inhibitors (canagliflozin, dapagliflozin, empagliflozin, ertugliflozin, sotagliflozin) are recommended in patients with diabetes at high risk of CV disease or with CV disease in order to prevent HF hospitalizations.</li> <li>• Counselling against sedentary habit, obesity, cigarette smoking, and alcohol abuse is recommended to prevent or delay the onset of HF.</li> </ul> <p><u>Recommendations for the initial management of patients with acute heart failure – pharmacotherapy</u></p> <ul style="list-style-type: none"> <li>• Intravenous loop diuretics are recommended for all patients with acute HF admitted with signs/symptoms of fluid overload to improve symptoms. It is recommended to regularly monitor symptoms, urine output, renal function and electrolytes during use of intravenous diuretics.</li> <li>• Combination of a loop diuretic with thiazide type diuretic should be considered in patients with resistant oedema who do not respond to an increase in loop diuretic doses.</li> <li>• In patients with acute HF and SBP &gt;110 mmHg, intravenous vasodilators may be considered as initial therapy to improve symptoms and reduce congestion.</li> <li>• Inotropic agents may be considered in patients with SBP &lt;90 mmHg and evidence of hypoperfusion who do not respond to standard treatment, including fluid challenge, to improve peripheral perfusion and maintain end-organ function.</li> <li>• Inotropic agents are not recommended routinely, due to safety concerns, unless the patient has symptomatic hypotension and evidence of hypoperfusion.</li> <li>• A vasopressor, preferably norepinephrine, may be considered in patients with cardiogenic shock to increase blood pressure and vital organ perfusion.</li> <li>• Thromboembolism prophylaxis (e.g., with LMWH) is recommended in patients not already anticoagulated and with no contraindication to anticoagulation, to reduce the risk of deep venous thrombosis and pulmonary embolism.</li> <li>• Routine use of opiates is not recommended, unless in selected patients with severe/intractable pain or anxiety.</li> </ul>
<p>American Heart Association/ American College of Cardiology/ Heart Rhythm Society: <b>2019</b> <b>AHA/ACC/HRS Focused update of the 2014 AHA/ACC/ARS Guideline for the Management of</b></p>	<p><u>Recommendations for risk-based anticoagulant therapy:</u> Class I</p> <ul style="list-style-type: none"> <li>• In patients with atrial fibrillation (AF), anticoagulant therapy should be individualized based on shared decision-making after discussion of the absolute and relative risks of stroke, bleeding and the patient’s values and preferences (Level of Evidence: C).</li> <li>• NOACs (dabigatran, rivaroxaban, apixaban, and edoxaban) are recommended over warfarin in NOAC-eligible patients with AF (except with moderate-to-severe mitral stenosis or a mechanical heart valve) (Level of Evidence: A).</li> <li>• Selection of anticoagulant therapy should be based on the risk of thromboembolism irrespective of whether the AF patter is paroxysmal, persistent, or permanent (Level of Evidence: B).</li> </ul>

Clinical Guideline	Recommendations
<p><b>Patients with Atrial Fibrillation (2019)<sup>25</sup></b></p>	<ul style="list-style-type: none"> <li>• In patients with AF (except with moderate-to-severe mitral stenosis or a mechanical heart valve), the CHA<sub>2</sub>DS<sub>2</sub>-VASc score is recommended for assessment of stroke risk (Level of Evidence: B). For patients with AF who have mechanical heart valves, warfarin is recommended. (Level of Evidence: B).</li> <li>• Selection of anticoagulant therapy should be based on the risk of thromboembolism, irrespective of whether the AF pattern is paroxysmal, persistent, or permanent.</li> <li>• For patients with AF and an elevated CHA<sub>2</sub>DS<sub>2</sub>-VASc score <math>\geq 2</math> in men or <math>\geq 3</math> in women, oral anticoagulants are recommended. Options include warfarin (Level of Evidence: A), dabigatran, rivaroxaban, apixaban, or edoxaban. (Level of Evidence: B).</li> <li>• Among patients treated with warfarin, the INR should be determined at least weekly during initiation of anticoagulant therapy and at least monthly when anticoagulation (INR in range) is stable (Level of Evidence: A)</li> <li>• For patients with AF (except with moderate-to-severe mitral stenosis or a mechanical heart valve) who are unable to maintain a therapeutic INR level with warfarin, use of a non-vitamin K oral anticoagulant (NOAC) is recommended (Level of Evidence: C-EO).</li> <li>• Re-evaluation of the need for and choice of anticoagulant therapy at periodic intervals is recommended to reassess stroke and bleeding risks (Level of Evidence: C).</li> <li>• Renal function should be evaluated prior to initiation of a NOAC and should be re-evaluated when clinically indicated and at least annually (Level of Evidence: B-NR).</li> <li>• For patients with atrial flutter, anticoagulant therapy is recommended according to the same risk profile used for AF (Level of Evidence: C).</li> </ul> <p><b>Class IIa</b></p> <ul style="list-style-type: none"> <li>• For patients with AF (except with moderate-to-severe mitral stenosis or a mechanical heart valve) and a CHA<sub>2</sub>DS<sub>2</sub>-VASc score of 0 in men or 1 in women, it is reasonable to omit antithrombotic therapy (Level of Evidence: B).</li> <li>• For patients with AF with a CHA<sub>2</sub>DS<sub>2</sub>-VASc score of <math>\geq 2</math> in men or <math>\geq 3</math> in women and who have end-stage chronic kidney disease (creatinine clearance <math>&lt; 15</math> mL/min) or who are on dialysis, it is reasonable to prescribe warfarin (INR 2.0 to 3.0) or apixaban for oral anticoagulation (Level of Evidence: B).</li> </ul> <p><b>Class IIb</b></p> <ul style="list-style-type: none"> <li>• For patients with AF (except with moderate-to-severe mitral stenosis or a mechanical heart valve) and a CHA<sub>2</sub>DS<sub>2</sub>-VASc score of 1 in men and 2 in women, prescribing an oral anticoagulant to reduce thromboembolic stroke risk may be considered. (Level of Evidence: C-LD).</li> <li>• For patients with AF (except with moderate-to-severe mitral stenosis or a mechanical heart valve) and moderate-to-severe chronic kidney disease with elevated CHA<sub>2</sub>DS<sub>2</sub>-VASc, treatment with reduced doses of direct thrombin or factor Xa inhibitors may be considered (e.g., dabigatran, rivaroxaban, apixaban, or edoxaban. <p>American Association for Thoracic Surgery: <b>2014 AATS Guidelines for the Prevention and Management of Peri-Operative Atrial Fibrillation</b></p>	<p><u>Recommended prevention strategies for all postoperative atrial fibrillation (POAF) patients</u></p> <ul style="list-style-type: none"> <li>• Patients taking <math>\beta</math>-blockers prior to thoracic surgery should continue them in the postoperative period to avoid <math>\beta</math>-blockade withdrawal.</li> <li>• Intravenous magnesium supplementation may be considered to prevent postoperative AF when serum magnesium level is low or it is suspected that total body magnesium is depleted.</li> <li>• Digoxin should not be used for prophylaxis against AF.</li> </ul>

Clinical Guideline	Recommendations
<p><b>and Flutter (POAF) for Thoracic Surgical Procedures (2014)<sup>27</sup></b></p>	<p><u>Recommended prevention strategies for intermediate to high-risk POAF patients</u></p> <ul style="list-style-type: none"> <li>• It is reasonable to administer diltiazem to those patients with preserved cardiac function who are not taking <math>\beta</math>-blockers preoperatively in order to prevent POAF.</li> <li>• It is reasonable to consider the postoperative administration of amiodarone to reduce the incidence of POAF for intermediate and high risk patients undergoing pulmonary resection.</li> <li>• Postoperative administration of intravenous amiodarone may be considered to prevent POAF in patients undergoing esophagectomy.</li> <li>• Atorvastatin may be considered to prevent POAF for statin naïve patients scheduled for intermediate and high risk thoracic surgical procedures.</li> </ul> <p><u>Rate control recommendations for patients with new onset POAF</u></p> <ul style="list-style-type: none"> <li>• Intravenous administration of <math>\beta</math>-blockers (e.g., esmolol or metoprolol) or nondihydropyridine calcium channel blockers (diltiazem or verapamil) is recommended to achieve rate control (heart rate <math>\leq 110</math> bpm) for patients who develop POAF with rapid ventricular response.</li> <li>• Caution should be used with patients with hypotension, left ventricular (LV) dysfunction, or heart failure.</li> <li>• Combination use of atrioventricular (AV) nodal blocking agents, such as <math>\beta</math>-blockers (e.g., esmolol or metoprolol), nondihydropyridine calcium channel antagonists (e.g., diltiazem or verapamil), or digoxin, can be useful to control heart rates when a single agent fails to control rates of POAF. The choice should be individualized and doses modified to avoid bradycardia.</li> <li>• For patients with hypotension, heart failure or LV dysfunction, or when other measures are unsuccessful or contraindicated, intravenous amiodarone can be useful for control of heart rate. Amiodarone could result in conversion to sinus rhythm, and if it is initiated after 48 hours of AF, both a transesophageal echocardiography (TEE) when possible, to rule out left atrial/LA appendage (LA/LAA) thrombus, and full anticoagulation should be considered.</li> <li>• For patients with heart failure, LV dysfunction or hypotension, intravenous digoxin may be considered for rate control of POAF.</li> <li>• For patients with ventricular preexcitation (i.e., Wolff-Parkinson-White syndrome) and POAF, use of AV nodal blocking agents, such as <math>\beta</math>-blockers (e.g., esmolol or metoprolol), intravenous amiodarone, nondihydropyridine calcium channel antagonists (e.g., diltiazem or verapamil), or digoxin, should be avoided.</li> </ul> <p><u>Recommendations for the use of antiarrhythmic drugs for pharmacologic cardioversion of POAF</u></p> <ul style="list-style-type: none"> <li>• Restoration of sinus rhythm with pharmacologic cardioversion is reasonable in patients with symptomatic, hemodynamically stable POAF. Intravenous amiodarone can be useful for pharmacologic cardioversion of POAF.</li> <li>• It is reasonable to administer antiarrhythmic medications in an attempt to maintain sinus rhythm for patients with recurrent or refractory POAF.</li> <li>• Amiodarone, sotalol, flecainide, propafenone, or dofetilide can be useful to maintain sinus rhythm in patients with POAF, depending on underlying heart disease, renal status and other comorbidities.</li> <li>• Flecainide or propafenone may be considered for pharmacologic cardioversion of POAF and maintenance of sinus rhythm if the patient has had no prior history of myocardial infarction, coronary artery disease, impaired LV function, significant LV hypertrophy, or valvular heart disease that is considered moderate or greater. These agents may need to be combined with an AV nodal blocking agent.</li> <li>• Intravenous ibutilide or procainamide may be considered for pharmacologic conversion of POAF for patients with structural heart disease and new onset POAF, but no hypotension or manifestations of congestive heart failure. Serum electrolytes and QTc interval must be within a normal range and patients must be closely</li> </ul>

Clinical Guideline	Recommendations
	<p>monitored during and for at least six hours after the infusion if either ibutilide or procainamide.</p> <ul style="list-style-type: none"> <li>• Intravenous ibutilide or procainamide may be considered for patients with POAF and an accessory pathway.</li> <li>• Flecainide and propafenone should not be used to treat POAF in patients with a history of a prior myocardial infarction, coronary artery disease, and/or severe structural heart disease, including severe left ventricular hypertrophy, or significantly reduced left ventricular ejection fraction.</li> <li>• Dronedarone should not be used for treatment of POAF in patients with heart failure.</li> </ul> <p><u>Recommendations for prevention of thromboembolism for patients with stable atrial fibrillation/flutter undergoing direct current cardioversion</u></p> <ul style="list-style-type: none"> <li>• For stable patients with POAF of 48-hours duration or longer, anticoagulation (with warfarin for INR 2.0 to 3.0, a novel oral anti-coagulant [NOAC] or LMWH) is recommended for at least three weeks prior to and four weeks after cardioversion, regardless of the method (electrical or pharmacological) used to restore sinus rhythm.</li> <li>• During the first 48 hours after the onset of POAF, the need for anticoagulation before and after direct current (DC) cardioversion may be based on the patient's risk of thromboembolism (CHA2DS2-VASc score) balanced by the risk of postoperative bleeding.</li> <li>• For POAF lasting longer than 48 hours, as an alternative to three weeks of therapeutic anticoagulation prior to cardioversion of POAF, it is reasonable to perform TEE in search of thrombus in the LA or LA appendage, preferably with full anticoagulation at the time of TEE in anticipation of DC cardioversion after the TEE.</li> <li>• For POAF lasting longer than 48 hours in patients who are not candidates for TEE (e.g., post-esophageal surgery), an initial rate control strategy combined with therapeutic anticoagulation using warfarin (aiming for INR 2.0 to 3.0), a direct thrombin inhibitor (e.g. dabigatran), factor Xa inhibitor (e.g. rivaroxaban, apixaban), or LMWH is recommended for at least three weeks prior to and four weeks after cardioversion.</li> <li>• Anticoagulation recommendations for cardioversion of atrial flutter are similar to those for atrial fibrillation.</li> <li>• For patients with an identified thrombus, cardioversion should not be performed until a longer period of anticoagulation is achieved (usually at least three weeks) and in accordance with established AF guidelines.</li> </ul> <p><u>Management of anticoagulation for new onset POAF</u></p> <ul style="list-style-type: none"> <li>• For the prevention of strokes for patients who develop POAF lasting longer than 48 hours, it is recommended to administer antithrombotic medications similarly to non-surgical patients. Anticoagulation within the first 48-hours of POAF should be considered based on the CHA2DS2-VASc risk score of the patient for stroke weighed against the risk of postoperative bleeding.</li> <li>• New oral anticoagulants (dabigatran, rivaroxaban, apixaban) are reasonable as an alternative to warfarin for patients who do not have a prosthetic heart valve, hemodynamically significant valve disease, and/or severe renal impairment or risk of GI bleeding.</li> <li>• It is reasonable to continue anticoagulation therapy for four weeks after the return of sinus rhythm because of the possibility of slowly resolving impairment of atrial contraction with an associated ongoing risk for thrombus formation and for delayed embolic events.</li> <li>• New oral anticoagulants should be avoided for patients at risk for serious bleeding (including GI bleeding) as they cannot be readily reversed. However, their use may</li> </ul>

Clinical Guideline	Recommendations
	<p>be recommended in situations where achievement of a therapeutic INR with warfarin has proved to be difficult.</p>
<p>Eighth Joint National Committee (JNC 8): <b>2014 Evidence-based Guideline for the Management of High Blood Pressure in Adults (2014)</b><sup>28</sup></p>	<ul style="list-style-type: none"> <li>• Pharmacologic treatment should be initiated in patients <math>\geq 60</math> years of age to lower blood pressure at systolic blood pressure <math>\geq 150</math> mm Hg or diastolic blood pressure <math>\geq 90</math> mm Hg and to a goal systolic blood pressure <math>&lt; 150</math> mm Hg and goal diastolic blood pressure <math>&lt; 90</math> mm Hg. Adjustment of treatment is not necessary if treatment results in lower blood pressure and treatment is well tolerated and without adverse effects on health or quality of life.</li> <li>• In patients <math>&lt; 60</math> years of age, pharmacologic treatment should be initiated to lower blood pressure at diastolic blood pressure <math>\geq 90</math> mm Hg to a goal diastolic blood pressure <math>&lt; 90</math> mm Hg.</li> <li>• In patients <math>&lt; 60</math> years of age, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure <math>\geq 150</math> mm Hg to a goal diastolic blood pressure <math>&lt; 140</math> mm Hg.</li> <li>• For patients <math>\geq 18</math> years of age with chronic kidney disease or diabetes, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure <math>\geq 140</math> mm Hg or diastolic blood pressure <math>\geq 90</math> mm Hg and to a goal systolic blood pressure <math>&lt; 140</math> mm Hg and goal diastolic blood pressure <math>&lt; 90</math> mm Hg.</li> <li>• Initial antihypertensive treatment for the general nonblack population, including those with diabetes, should include thiazide-type diuretic, calcium channel blocker (CCB), ACE inhibitor, or ARB.</li> <li>• Initial antihypertensive treatment for the general black population, including those with diabetes, should include thiazide-type diuretic or CCB.</li> <li>• For patients <math>\geq 18</math> years of age with chronic kidney disease regardless of race or diabetes status, initial (or add-on) treatment should include an ACE inhibitor or ARB to improve kidney outcomes.</li> <li>• The main goal of antihypertensive treatment is to attain and maintain goal blood pressure.</li> <li>• If goal blood pressure is not attained within a month of treatment, the dose of the initial drug should be increased or second drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• If goal is not achieved with two drugs, a third drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• An ACE inhibitor and ARB should not be used together.</li> <li>• Antihypertensive classes can be used if the patient is unable to achieve goal blood pressure with three agents or had a contraindication to a preferred class.</li> <li>• If blood pressure is not able to be achieved or in complicated patients, referral to a hypertension specialist may be indicated.</li> </ul>
<p>International Society of Hypertension: <b>Global Hypertension Practice Guidelines (2020)</b><sup>29</sup></p>	<p><b>Lifestyle modifications</b></p> <ul style="list-style-type: none"> <li>• Lifestyle modification is the first line of antihypertensive treatment.</li> <li>• Salt reduction: Reduce salt added when preparing foods, and at the table. Avoid or limit consumption of high salt foods such as soy sauce, fast foods and processed food including breads and cereals high in salt.</li> <li>• Healthy diet: Eating a diet that is rich in whole grains, fruits, vegetables, polyunsaturated fats and dairy products and reducing food high in sugar, saturated fat and trans fats, such as the DASH diet.</li> <li>• Healthy drinks: Moderate consumption of coffee, green and black tea. Other beverages that can be beneficial include karkadé (hibiscus) tea, pomegranate juice, beetroot juice and cocoa.</li> <li>• Moderation of alcohol consumption: The recommended daily limit for alcohol consumptions is 2 standard drinks for men and 1.5 for women (10 g alcohol/standard drink). Avoid binge drinking.</li> <li>• Weight reduction: Body weight control is indicated to avoid obesity. Particularly abdominal obesity should be managed. Ethnic-specific cut-offs for BMI and waist</li> </ul>

Clinical Guideline	Recommendations
	<p>circumference should be used. Alternatively, a waist-to-height ratio <math>&lt;0.5</math> is recommended for all populations.</p> <ul style="list-style-type: none"> <li>• Smoking cessation: Smoking is a major risk factor for cardiovascular disease (CVD), COPD and cancer. Smoking cessation and referral to smoking cessation programs are advised.</li> <li>• Regular physical activity: Studies suggest that regular aerobic and resistance exercise may be beneficial for both the prevention and treatment of hypertension. Moderate intensity aerobic exercise (walking, jogging, cycling, yoga, or swimming) for 30 minutes on five to seven days per week Strength training also can help reduce blood pressure. Performance of resistance/strength exercises on two to three days per week.</li> <li>• Reduce stress and induce mindfulness: Stress should be reduced and mindfulness or meditation introduced into the daily routine.</li> <li>• Reduce exposure to air pollution and cold temperature: Evidence from studies support a negative effect of air pollution on blood pressure in the long-term.</li> </ul> <p><u>Pharmacological Treatment</u></p> <ul style="list-style-type: none"> <li>• Ideal characteristics of drug treatment             <ul style="list-style-type: none"> <li>○ Treatments should be evidence-based in relation to morbidity/mortality prevention.</li> <li>○ Use a once-daily regimen which provides 24-hour blood pressure control.</li> <li>○ Treatment should be affordable and/or cost-effective relative to other agents.</li> <li>○ Treatments should be well-tolerated.</li> <li>○ Evidence of benefits of use of the medication in populations to which it is to be applied.</li> </ul> </li> <li>• General scheme for drug treatment             <ul style="list-style-type: none"> <li>○ Lifestyle modification is the first line of antihypertensive treatment.</li> <li>○ Grade 1 hypertension (BP 140 to 159/ 90 to 99): Immediate drug treatment in high-risk patients or those with CVD, chronic kidney disease (CKD), diabetes mellitus (DM), or hypertension-mediated organ damage (HMOD). Drug treatment after three to six months of lifestyle intervention if BP still not controlled in low to moderate risk patients.</li> <li>○ Grade 2 hypertension (BP <math>\geq 160/100</math>): Immediate drug treatment in all patients.</li> </ul> </li> <li>• Core drug-treatment strategy             <ul style="list-style-type: none"> <li>○ Step 1: Dual low-dose combination (ACE inhibitor or ARB plus dihydropyridine-calcium channel blockers (DHP-CCB)); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq 80</math> years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance; consider ACE/ARB plus DHP-CCB or DHP-CCB plus thiazide-like diuretics in black patients.</li> <li>○ Step 2: Dual full-dose combination (ACE inhibitor or ARB plus DHP-CCB); consider monotherapy in low-risk grade 1 hypertension or in very old (<math>\geq 80</math> years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance.</li> <li>○ Step 3: Triple combination (ACE/ARB plus DHP-CCB plus thiazide-like diuretic).</li> <li>○ Step 4, resistant hypertension: triple combination plus spironolactone or other drug, alternatives include amiloride, doxazosin, eplerenone, clonidine, or <math>\beta</math>-blocker. Caution with spironolactone or other potassium sparing diuretics when estimated GFR <math>&lt;45</math> mL/min/1.73m<sup>2</sup> or K<sup>+</sup> <math>&gt;4.5</math> mmol/L.</li> <li>○ Consider <math>\beta</math>-blockers at any treatment step when there is a specific indication for their use, e.g., heart failure, angina, post-MI, atrial</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
<p>Hypertension            Canada:  <b>2020 Guidelines for the Prevention, Diagnosis, Risk Assessment, and Treatment of Hypertension in Adults and Children (2020)</b><sup>30</sup></p>	<p>fibrillation, or younger women planning pregnancy or pregnant.</p> <p><u>Indications for drug therapy for adults with hypertension without compelling indications for specific agents</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive therapy should be prescribed for average diastolic blood pressure (DBP) measurements of <math>\geq 100</math> mmHg or average systolic blood pressure (SBP) measurements of <math>\geq 160</math> mmHg in patients without macrovascular target organ damage or other cardiovascular risk factors.</li> <li>• Antihypertensive therapy should be strongly considered for average DPB readings <math>\geq 90</math> mmHg or for average SBP readings <math>\geq 140</math> mmHg in the presence of macrovascular target organ damage or other independent cardiovascular risk factors.</li> <li>• For high-risk patients, aged 50 years or older, with SBP levels <math>\geq 130</math> mmHg, intensive management to target a SBP <math>&lt; 120</math> mmHg should be considered. Patient selection for intensive management is recommended and caution should be taken in certain high-risk groups.</li> </ul> <p><u>Indications for drug therapy for adults with diastolic and with or without systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be with either monotherapy or single pill combination (SPC).               <ul style="list-style-type: none"> <li>○ Recommended monotherapy choices are:                   <ul style="list-style-type: none"> <li>▪ A thiazide/thiazide-like diuretic, with longer-acting diuretics preferred;</li> <li>▪ A <math>\beta</math>-blocker (in patients <math>&lt; 60</math> years of age);</li> <li>▪ An angiotensin-converting enzyme (ACE) inhibitor (in nonblack patients);</li> <li>▪ An angiotensin receptor blocker (ARB); or</li> <li>▪ A long-acting calcium channel blocker (CCB).</li> </ul> </li> <li>○ Recommended SPC choices are those in which an ACE inhibitor is combined with a CCB, ARB with a CCB, or ACE inhibitor or ARB with a diuretic.</li> <li>○ Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> </ul> </li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line choices. Useful choices include a thiazide/thiazide-like diuretic or CCB with either: ACE inhibitor, ARB, or <math>\beta</math>-blocker. Caution should be exercised in combining a nondihydropyridine CCB and a <math>\beta</math>-blocker. The combination of an ACE inhibitor and an ARB is not recommended.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other antihypertensive drugs may be added.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated hypertension; <math>\beta</math>-blockers are not recommended as first-line therapy for uncomplicated hypertension in patients <math>\geq 60</math> years of age; and ACE inhibitors are not recommended as first-line therapy for uncomplicated hypertension in black patients. However, these agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Indications for drug therapy for adults with isolated systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be single-agent therapy with a thiazide/thiazide-like diuretic, a long-acting dihydropyridine CCB, or an ARB. If there are adverse effects, another drug from this group should be substituted. Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line options.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or</li> </ul>

Clinical Guideline	Recommendations
	<p>there are adverse effects, other classes of drugs (such as <math>\alpha</math>-blockers, ACE inhibitors, centrally acting agents, or nondihydropyridine CCBs) may be combined or substituted.</p> <ul style="list-style-type: none"> <li>Possible reasons for poor response to therapy should be considered.</li> <li><math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated isolated systolic hypertension; and <math>\beta</math>-blockers are not recommended as first-line therapy for isolated systolic hypertension in patients <math>\geq 60</math> years of age. However, both agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Guidelines for hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>For most hypertensive patients with CAD, an ACE inhibitor or ARB is recommended.</li> <li>For hypertensive patients with CAD, but without coexisting systolic heart failure, the combination of an ACE inhibitor and ARB is not recommended.</li> <li>For high-risk hypertensive patients, when combination therapy is being used, choices should be individualized. The combination of an ACE inhibitor and a dihydropyridine CCB is preferable to an ACE inhibitor and a thiazide/thiazide-like diuretic in selected patients.</li> <li>For patients with stable angina pectoris but without previous heart failure, myocardial infarction, or coronary artery bypass surgery, either a <math>\beta</math>-blocker or CCB can be used as initial therapy.</li> <li>Short-acting nifedipine should not be used.</li> <li>When decreasing SBP to target levels in patients with established CAD (especially if isolated systolic hypertension is present), be cautious when the DBP is <math>\leq 60</math> mmHg because of concerns that myocardial ischemia might be exacerbated, especially in patients with left ventricular hypertrophy (LVH).</li> </ul> <p><u>Guidelines for patients with hypertension who have had a recent myocardial infarction</u></p> <ul style="list-style-type: none"> <li>Initial therapy should include a <math>\beta</math>-blocker as well as an ACE inhibitor.</li> <li>An ARB can be used if the patient is intolerant of an ACE inhibitor.</li> <li>CCBs may be used in patients after myocardial infarction when <math>\beta</math>-blockers are contraindicated or not effective. Nondihydropyridine CCBs should not be used when there is heart failure, evidenced by pulmonary congestion on examination or radiography.</li> </ul> <p><u>Treatment of hypertension in association with heart failure</u></p> <ul style="list-style-type: none"> <li>In patients with systolic dysfunction (ejection fraction <math>&lt; 40\%</math>), ACE inhibitors and <math>\beta</math>-blockers are recommended for initial therapy. Aldosterone antagonists (mineralocorticoid receptor antagonists) may be combined in treatment for patients with a recent cardiovascular hospitalization, acute myocardial infarction, elevated B-type natriuretic peptide or N-terminal pro-B-type natriuretic peptide level, or New York Heart Association (NYHA) Class II-IV symptoms. Careful monitoring for hyperkalemia is recommended when combining an aldosterone antagonist with ACE inhibitor or ARB treatment. Other diuretics are recommended as additional therapy if needed. Beyond considerations of BP control, doses of ACE inhibitors or ARBs should be titrated to those reported to be effective in trials unless adverse effects become manifest.</li> <li>An ARB is recommended if ACE inhibitors are not tolerated.</li> <li>A combination of hydralazine and isosorbide dinitrate is recommended if ACE inhibitors and ARBs are contraindicated or not tolerated.</li> <li>For hypertensive patients whose BP is not controlled, an ARB may be combined with an ACE inhibitor and other antihypertensive drug treatment. Careful monitoring should be used if combining an ACE inhibitor and an ARB because of potential adverse effects such as hypotension, hyperkalemia, and worsening renal</li> </ul>

Clinical Guideline	Recommendations
	<p>function. Additional therapies may also include dihydropyridine CCBs.</p> <ul style="list-style-type: none"> <li>• An angiotensin receptor-neprilysin inhibitor (ARNI) should be used in place of an ACE inhibitor or ARB for patients with HFrEF (&lt;40%) who remain symptomatic despite treatment with appropriate dose of guideline directed HF therapy. Eligible patients must have a serum potassium &lt;5.2 mmol/L, an eGFR <math>\leq</math>30 mL/min/1.73m<sup>2</sup> and close surveillance of serum potassium and creatinine.</li> </ul> <p><u>Treatment of hypertension in association with stroke</u></p> <ul style="list-style-type: none"> <li>• BP management in acute ischemic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> <li>• BP management after acute ischemic stroke <ul style="list-style-type: none"> <li>○ Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack.</li> <li>○ After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently &lt;140/90 mmHg.</li> <li>○ Treatment with an ACE inhibitor and thiazide/thiazide-like diuretic combination is preferred.</li> <li>○ For patients with stroke, the combination of an ACE inhibitor and ARB is not recommended.</li> </ul> </li> <li>• BP management in hemorrhagic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> </ul> <p><u>Treatment of hypertension in association with LVH</u></p> <ul style="list-style-type: none"> <li>• Hypertensive patients with LVH should be treated with antihypertensive therapy to decrease the rate of subsequent cardiovascular events.</li> <li>• The choice of initial therapy can be influenced by the presence of LVH. Initial therapy can be drug treatment using ACE inhibitors, ARBs, long-acting CCBs, or thiazide/thiazide-like diuretics. Direct arterial vasodilators such as hydralazine or minoxidil should not be used.</li> </ul> <p><u>Treatment of hypertension in association with nondiabetic chronic kidney disease</u></p> <ul style="list-style-type: none"> <li>• Individualize BP targets in patients with chronic kidney disease. Consider intensive targets (SBP &lt;120 mmHg) in appropriate patients.</li> <li>• For patients with hypertension and proteinuric chronic kidney disease (urinary protein &gt;150 mg per 24 hours or albumin to creatinine ratio &gt;30 mg/mmol), initial therapy should be an ACE inhibitor or an ARB if there is intolerance to ACE inhibitors.</li> <li>• In most cases, combination therapy with other antihypertensive agents might be needed to reach target BP levels.</li> <li>• The combination of an ACE inhibitor and ARB is not recommended for patients with nonproteinuric chronic kidney disease.</li> </ul> <p><u>Treatment of hypertension in association with renovascular disease</u></p> <ul style="list-style-type: none"> <li>• Patients with hypertension attributable to atherosclerotic renal artery stenosis should be primarily medically managed because renal angioplasty and stenting offers no benefit over optimal medical therapy alone.</li> <li>• Renal artery angioplasty and stenting for atherosclerotic hemodynamically significant renal artery stenosis could be considered for patients with uncontrolled hypertension resistant to maximally tolerated pharmacotherapy, progressive renal function loss, and acute pulmonary edema.</li> <li>• Patients with confirmed renal fibromuscular dysplasia (FMD) should be referred to a hypertension specialist.</li> <li>• Renal artery angioplasty without stenting is recommended for treatment of FMD-related renal artery stenosis. Stenting is not recommended unless needed because of a periprocedural dissection. Surgical revascularization should be considered in</li> </ul>

Clinical Guideline	Recommendations
	<p>cases of complex lesions less amenable to angioplasty, stenosis associated with complex aneurysm, and restenosis despite two unsuccessful attempts of angioplasty.</p> <p><u>Treatment of hypertension in association with diabetes mellitus</u></p> <ul style="list-style-type: none"> <li>• Persons with diabetes mellitus should be treated to attain SBP of &lt;130 mmHg and DBP of &lt;80 mmHg.</li> <li>• For persons with cardiovascular or kidney disease, including microalbuminuria, or with cardiovascular risk factors in addition to diabetes and hypertension, an ACE inhibitor or an ARB is recommended as initial therapy.</li> <li>• For persons with diabetes and hypertension not included in other guidelines in this section, appropriate choices include (in alphabetical order): ACE inhibitors, ARBs, dihydropyridine CCBs, and thiazide/thiazide-like diuretics.</li> <li>• If target BP levels are not achieved with standard-dose monotherapy, additional antihypertensive therapy should be used. For persons in whom combination therapy with an ACE inhibitor is being considered, a dihydropyridine CCB is preferable to a thiazide/thiazide-like diuretic.</li> </ul> <p><u>Resistant hypertension</u></p> <ul style="list-style-type: none"> <li>• Resistant hypertension is defined as BP above target despite three or more BP-lowering drugs at optimal doses preferably including a diuretic (and usually a renin-angiotensin-aldosterone system blocker and a CCB).</li> <li>• Accurate office and out-of-office BP measurement is essential.</li> <li>• Other reasons for apparent resistant hypertension should be eliminated before diagnosing true resistant hypertension, including nonadherence, white coat effect, and secondary hypertension.</li> <li>• Pharmacotherapy with the additional use of spironolactone, bisoprolol, doxazosin, amiloride, eplerenone, or clonidine with the baseline regimen decreases BP significantly, with the greatest BP-lowering shown with spironolactone.</li> <li>• Patients with resistant hypertension should be referred to providers with expertise in diagnosis and management of hypertension.</li> </ul> <p><u>Hypertension and pediatrics</u></p> <ul style="list-style-type: none"> <li>• BP should be measured regularly in children three years of age or older; the auscultatory method is the gold-standard at present.</li> <li>• Initial therapy should be monotherapy, with an ACE inhibitor or ARB (not first-line in black children), or a long-acting dihydropyridine CCB.</li> <li>• The treatment goal is systolic and diastolic office BP and/or ABPM &lt; 95th percentile or &lt;90<sup>th</sup> percentile in children with risk factors or target organ damage.</li> <li>• Complex cases should be referred to an expert in pediatric hypertension.</li> </ul> <p><u>Hypertension and pregnancy</u></p> <ul style="list-style-type: none"> <li>• Up to 7% of pregnancies are complicated by a hypertensive disorder of pregnancy, and approximately 5% of women will have chronic hypertension when they become pregnant.</li> <li>• The prevalence of hypertension in pregnancy is expected to increase with women becoming pregnant later in their reproductive years and the increasing prevalence of cardiovascular comorbidities such as increased preconception body mass index and maternal diabetes.</li> <li>• The possibility of pregnancy should be considered when managing women with hypertension who are of reproductive age.</li> <li>• Preconception counselling should be offered to all women with hypertension who are considering pregnancy.</li> <li>• ACE inhibitor and ARB therapy should be avoided before conception and during pregnancy unless there is a compelling indication for their use (i.e., proteinuric</li> </ul>

Clinical Guideline	Recommendations
	<p>kidney disease).</p> <ul style="list-style-type: none"> <li>• Hypertension during pregnancy can increase the risk of adverse maternal and fetal outcomes, including an increased risk of preeclampsia, placental abruption, prematurity, small for gestational age infants, stillbirth, and maternal renal and retinal injury, thus generally requires involvement of an interdisciplinary team including obstetrical care providers.</li> <li>• Antihypertensive therapy is recommended for average SBP measurements of <math>\geq 140</math> mmHg or DBP measurements of <math>\geq 90</math> mmHg in pregnant women with chronic hypertension, gestational hypertension, or preeclampsia. Initial antihypertensive therapy should be monotherapy from the following first-line drugs: oral labetalol, oral methyldopa, long-acting oral nifedipine, or other oral b-blockers (acebutolol, metoprolol, pindolol, and propranolol). Other antihypertensive drugs can be considered as second-line drugs including: clonidine, hydralazine, and thiazide diuretics.</li> <li>• Women with severe hypertension with SBP <math>\geq 160</math> mmHg or DBP <math>\geq 110</math> mmHg in pregnancy or postpartum require urgent antihypertensive therapy because it is considered an obstetrical emergency.</li> <li>• Antihypertensive drugs used in breastfeeding women include: labetalol, methyldopa, long-acting nifedipine, enalapril, or captopril.</li> </ul>
<p>European Society of Hypertension/          European Society of Cardiology:  <b>2018 Guidelines for the management of arterial hypertension (2018)</b><sup>31</sup></p>	<p><u>Treatment strategies and choice of antihypertensive drugs</u></p> <ul style="list-style-type: none"> <li>• Diuretics (including thiazides, chlorthalidone, and indapamide), <math>\beta</math>-blockers, calcium channel blocker (CCB), angiotensin-converting enzyme (ACE) inhibitors, and angiotensin receptor blockers (ARBs) are all suitable for the initiation and maintenance of antihypertensive treatment, either as monotherapy or in some combinations.</li> <li>• Some agents should be considered as the preferential choice in specific conditions because used in trials in those conditions or because of greater effectiveness in specific types of organ damage. Preferred combinations should comprise a renin-angiotensin system (RAS) blocker (either an ACE inhibitor or an ARB) with a CCB or diuretic.</li> <li>• It is recommended that beta-blockers are combined with any of the other major drug classes when there are specific clinical situations, e.g. angina, post-myocardial infarction, heart failure, or heart rate control.</li> <li>• Initiation of antihypertensive therapy with a two-drug combination may be considered in patients with markedly high baseline blood pressure (BP) or at high cardiovascular (CV) risk.</li> <li>• The combination of two antagonists of the RAS is not recommended and should be discouraged.</li> <li>• Other drug combinations should be considered and probably are beneficial in proportion to the extent of BP reduction. However, combinations that have been successfully used in trials may be preferable.</li> <li>• Combinations of two antihypertensive drugs at fixed doses in a single tablet may be recommended and favored, because reducing the number of daily pills improves adherence, which is low in patients with hypertension. Exceptions are frail older patients and those at low risk and with grade one hypertension (particularly if systolic BP is <math>&lt; 150</math> mmHg).</li> <li>• It is recommended that if BP is not controlled with a three-drug combination, treatment should be increased by the addition of spironolactone or, if not tolerated, other diuretics such as amiloride or higher doses of other diuretics, a beta-blocker, or an alpha-blocker.</li> </ul> <p><u>Treatment strategies in white-coat and masked hypertension</u></p> <ul style="list-style-type: none"> <li>• In white-coat hypertensives without additional risk factors, therapeutic intervention may be limited to lifestyle changes only, but this decision should be accompanied by close follow-up.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In white-coat hypertensives with a higher CV risk or hypertension-mediated organ damage, drug treatment may be considered in addition to lifestyle changes.</li> <li>• In masked hypertension, both lifestyle measures and antihypertensive drug treatment should be considered, because this type of hypertension has been consistently found to have a CV risk very close to that of in- and out-of-office hypertension.</li> <li>• Antihypertensive drug up-titration should be considered in treated patients whose out-of-office BP is not controlled (i.e., masked uncontrolled hypertension), because of the high CV risk of these patients.</li> </ul> <p><u>Antihypertensive treatment strategies in the elderly</u></p> <ul style="list-style-type: none"> <li>• It is recommended that older patients (<math>\geq 65</math> years) are treated with the same recommendations in non-older patient population. In very old patients (<math>\geq 80</math> years), it may be appropriate to initiate treatment with monotherapy.</li> <li>• In all older patients, when combination therapy is used, it is recommended that this is initiated at the lowest available doses. In all older patients, and especially very old or frail patients, the possible occurrence of postural BP should be closely monitored and symptoms of possible hypotensive episodes checked by ambulatory blood pressure monitoring.</li> <li>• Unless required for concomitant diseases, loop diuretics and alpha-blockers should be avoided because of their association with injurious falls.</li> <li>• Renal function should be frequently assessed to detect possible increases in serum creatinine and reductions in estimated glomerular filtration rate (eGFR) as a result of BP-related reductions in renal perfusion.</li> <li>• When treated, BP should be lowered to a systolic value of 130 to 139 mmHg and a diastolic value of <math>&lt; 80</math> mmHg if tolerated. Treated values of <math>&lt; 130</math> mmHg should be avoided.</li> </ul> <p><u>Treatment strategies in hypertensive women</u></p> <ul style="list-style-type: none"> <li>• Hormone therapy and selective estrogen receptor modulators are not recommended and should not be used for primary or secondary prevention of CVD.</li> <li>• In women with gestational hypertension, pre-existing hypertension superimposed by gestational hypertension, or with hypertension and subclinical organ damage or symptoms, initiation of drug treatments is recommended when SBP is <math>\geq 140</math> mmHg or DBP <math>\geq 90</math> mmHg. In all other cases, initiation of drug treatment is recommended when SBP is <math>\geq 150</math> mmHg or DBP is <math>\geq 95</math> mmHg.</li> <li>• Methyldopa, labetalol, and CCBs are recommended as the drugs of choice for the treatment of hypertension in pregnancy.</li> <li>• ACE inhibitors, ARBs, or direct renin inhibitors are not recommended during pregnancy.</li> <li>• SBP <math>\geq 170</math> mmHg or DBP <math>\geq 110</math> mmHg in a pregnant woman is an emergency, and admission to hospital is recommended.</li> <li>• In severe hypertension, drug treatment with intravenous (IV) labetalol, oral methyldopa, or nifedipine is recommended.</li> <li>• The recommended treatment for hypertensive crisis is IV labetalol or nicardipine and magnesium.</li> <li>• In pre-eclampsia associated with pulmonary edema, nitroglycerin given as an IV infusion is recommended.</li> <li>• In women with gestational hypertension or mild-pre-eclampsia, delivery is recommended at 37 weeks.</li> <li>• It is recommended to expedite delivery in pre-eclampsia with adverse conditions, such as visual disturbances or hemostatic disorders</li> <li>• In women at high risk of pre-eclampsia, provided they are at low risk of gastrointestinal hemorrhage, treatment with low dose aspirin from 12 weeks until delivery may be considered.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Methyldopa, labetalol, and nifedipine should be considered preferential antihypertensive drugs in pregnancy. Intravenous labetalol or infusion of nitroprusside should be considered in case of emergency (pre-eclampsia).</li> </ul> <p><u>Treatment strategies in patients with diabetes</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive drug treatment is recommended for people with diabetes when office BP is <math>\geq 140/90</math> mmHg.</li> <li>• A SBP goal <math>&lt; 130</math> mmHg is recommended in patients with diabetes and <math>&lt; 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg.</li> <li>• In older people, the target SBP range is 130 to 139 mmHg.</li> <li>• The DBP target in patients with diabetes is recommended to be <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• It is recommended to initiate treatment with a combination of a RAS blocker with a CCB or thiazide/thiazide-like diuretic.</li> <li>• It is recommended that individual drug choice takes comorbidities into account.</li> <li>• Simultaneous administration of two blockers of the RAS is not recommended and should be avoided in patients with diabetes.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with nephropathy</u></p> <ul style="list-style-type: none"> <li>• In patients with diabetic and non-diabetic CKD, it is recommended that an office BP of <math>\geq 140/90</math> mmHg be treated with lifestyle advice and BP-lowering medication.</li> <li>• In patients with diabetic or non-diabetic CKD, it is recommended to lower SBP to a range of 130 to 139 mmHg. And individualized treatments should be considered according to its tolerability and impact on renal function and electrolytes.</li> <li>• A combination of a RAS blocker with a CCB or a diuretic is recommended as initial therapy.</li> <li>• RAS blockers are more effective in reducing albuminuria than other antihypertensive agents, and are indicated in hypertensive patients in the presence of microalbuminuria or overt proteinuria.</li> <li>• Combination of two RAS blockers, though potentially more effective in reducing proteinuria, is not recommended.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with cerebrovascular disease</u></p> <ul style="list-style-type: none"> <li>• In patients with acute intracerebral hemorrhage, immediate BP lowering is not recommended for patients with SBP <math>&lt; 220</math> mmHg. In patients with SBP <math>\geq 220</math> mmHg, care acute BP lowering with IV therapy to <math>&lt; 180</math> mmHg should be considered.</li> <li>• In acute ischemic stroke, routine BP lowering with antihypertensive therapy is not recommended with the exceptions with the exceptions: in patients with acute ischemic stroke who are eligible for IV thrombolysis, BP should be carefully lowered and maintained at <math>&lt; 180/105</math> mmHg for at least the first 24 hours after thrombolysis; In patients with markedly elevated BP who do not receive fibrinolysis, drug therapy may be considered, based on clinical judgement, to reduce BP by 15% during the first 24 hours after the stroke onset.</li> <li>• In hypertensive patients with an acute cerebrovascular event, antihypertensive treatment is recommended immediately for transient ischemic attack (TIA) and after several days in ischemic stroke.</li> <li>• In all hypertensive patients with ischemic stroke or TIA, an SBP target range of 120 to 130 mmHg should be considered.</li> <li>• The recommended antihypertensive drug treatment strategy for stroke prevention is a RAS blocker plus a CCB or a thiazide-like diuretic.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with heart failure (HF) or left ventricular hypertrophy (LVH)</u></p> <ul style="list-style-type: none"> <li>• In hypertensive patients with heart failure (with reduced or preserved ejection</li> </ul>

Clinical Guideline	Recommendations
	<p>fraction), BP-lowering treatment should be considered if <math>\geq 140/90</math> mmHg.</p> <ul style="list-style-type: none"> <li>• In patients with HF<sub>r</sub>EF, it is recommended that BP-lowering treatment comprises an ACE inhibitor or ARB, and a beta-blocker and a diuretic and/or mineralocorticoid receptor antagonist (MRA) if required.</li> <li>• Dihydropyridine CCBs may be added if BP control is not achieved.</li> <li>• In patients with HF<sub>p</sub>EF, BP treatment threshold and target values should be the same as for HF<sub>r</sub>EF).</li> <li>• Because no specific drug has proven its superiority, all major agents can be used.</li> <li>• In all patients with LVH, it is recommended to treat with a RAS blocker or in combination with a CCB or diuretic and SBP should be lowered to a range of 120 to 130 mmHg.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• In patients with CAD receiving BP-lowering drugs, it is recommended to target SBP to <math>\leq 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg. In older patients, the target is an SBP range of 130 to 140 mmHg. The target DBP is <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• In hypertensive patients with a history of myocardial infarction, beta-blockers and RAS blockers are recommended as part of treatment.</li> <li>• In patients with asymptomatic angina, beta-blockers and/or CCBs are recommended.</li> </ul>
<p>National Institute for Health and Clinical Excellence: <b>Hypertension in adults: diagnosis and management (2019)</b><sup>32</sup></p>	<p><u>Choosing antihypertensive drug treatment (for people with or without type II diabetes)</u></p> <ul style="list-style-type: none"> <li>• Where possible, recommend treatment with drugs taken only once a day.</li> <li>• Prescribe non-proprietary drugs where these are appropriate and minimize cost.</li> <li>• Offer people with isolated systolic hypertension (systolic blood pressure <math>\geq 160</math> mmHg) the same treatment as people with both raised systolic and diastolic blood pressure.</li> <li>• Offer antihypertensive drug treatment to women of child-bearing potential with diagnosed hypertension in line with recommendations in this guideline. For women considering pregnancy or who are pregnant or breastfeeding, manage hypertension in line with the recommendations on Management of pregnancy with chronic hypertension and Breastfeeding in 'Hypertension in pregnancy'.</li> <li>• When choosing antihypertensive drug treatment for adults of black African or African-Caribbean family origin, consider an angiotensin II receptor blocker, in preference to an angiotensin-converting enzyme inhibitor.</li> </ul> <p><u>Step one treatment</u></p> <ul style="list-style-type: none"> <li>• Patients <math>&lt; 55</math> years of age should be offered a step one antihypertensive with an angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB).</li> <li>• Offer an ACE inhibitor or an ARB to adults starting step 1 antihypertensive treatment who have type II diabetes and are of any age or family origin or those aged <math>&lt; 55</math> years but not of black African or African-Caribbean family origin.</li> <li>• If an ACE inhibitor is not tolerated, offer an ARB.</li> <li>• Do not combine an ACE inhibitor with an ARB for the treatment of hypertension.</li> <li>• Offer a calcium channel blocker (CCB) to adults starting step 1 antihypertensive treatment who are <math>&gt; 55</math> years of age and do not have diabetes and are of black African or African-Caribbean family origin and do not have type II diabetes and of any age.</li> <li>• If a CCB is not suitable, for example because of edema or intolerance, or if there is evidence of heart failure or a high risk of heart failure, offer a thiazide-like diuretic.</li> <li>• If diuretic treatment is to be initiated or changed, offer a thiazide-like diuretic, such as indapamide in preference to a conventional thiazide diuretic such as bendroflumethiazide or hydrochlorothiazide.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• For adults with hypertension who are already receiving treatment with bendroflumethiazide or hydrochlorothiazide, who have stable, well-controlled blood pressure, continue with their treatment.</li> </ul> <p><u>Step two treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering next step treatment for hypertension discuss with the person if they are taking their medicine as prescribed and support adherence in line with NICE's guideline on “Medicines adherence: involving patients decisions about prescribed medicines and supporting adherence”.</li> <li>• If hypertension is not controlled with a step one treatment of an ACE inhibitor or ARB, offer choice of one of the following drugs in addition to the step one treatment: a CCB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults taking step one treatment of a CCB, offer the choice of one of the following drugs in addition to the step one treatment: an ACE inhibitor or an ARB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults of black African or African–Caribbean family origin who do not have type 2 diabetes taking step one treatment, consider an ARB, in preference to an ACE inhibitor, in addition to step one treatment.</li> </ul> <p><u>Step three treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering step three treatment, review the person’s medications to ensure they are being taken at the optimal doses and discuss adherence (see recommendation under step two).</li> <li>• If hypertension is not controlled in adults taking step two treatment, offer a combination of an ACE inhibitor or ARB and a CCB and a thiazide-like diuretic.</li> </ul> <p><u>Step four treatment</u></p> <ul style="list-style-type: none"> <li>• If hypertension is not controlled in adults taking the optimal tolerated doses of an ACE inhibitor or an ARB plus a CCB and a thiazide-like diuretic, regard them as having resistant hypertension.</li> <li>• Before considering further treatment for a person with resistant hypertension, confirm elevated clinic blood pressure measurements using ambulatory or home blood pressure recordings, assess for postural hypotension, and discuss adherence.</li> <li>• For people with confirmed resistant hypertension, consider adding a fourth antihypertensive drug as step four treatment or seeking specialist advice.</li> <li>• Consider further diuretic therapy with low-dose spironolactone for adults with resistant hypertension starting step four treatment who have a blood potassium level of 4.5 mmol/l or less. Use particular caution in people with a reduced estimated glomerular filtration rate because they have an increased risk of hyperkalemia.</li> <li>• When using further diuretic therapy for step four treatment of resistant hypertension, monitor blood sodium and potassium and renal function within one month of starting treatment and repeat as needed thereafter.</li> <li>• Consider an alpha-blocker or beta-blocker for adults with resistant hypertension starting step four treatment who have a blood potassium level of more than 4.5 mmol/l.</li> <li>• If blood pressure remains uncontrolled in people with resistant hypertension taking the optimal tolerated doses of four drugs, seek specialist advice.</li> </ul>
<p>International Society on Hypertension in Blacks:  <b>Management of High Blood Pressure in Blacks</b></p>	<ul style="list-style-type: none"> <li>• To attain and maintain blood pressure (BP) below target levels, multiple antihypertensive drugs will be required in most hypertensive blacks.</li> <li>• Use of two-drug combination therapy when SBP is &gt;15 mm Hg and/or DBP is &gt;10 mm Hg above goal levels is increasingly recommended as first-line therapy.</li> <li>• Two-drug regimens have generally contained a thiazide-type diuretic; however, the combination of a calcium channel blocker (CCB) with either an ACE inhibitor or</li> </ul>

Clinical Guideline	Recommendations
(2010) <sup>33</sup>	<p>an ARB has been shown equally efficacious in BP lowering but with demonstrated superiority (CCB+ACE) for hard clinical outcomes compared with the same ACE inhibitor plus a thiazide-type diuretic.</p> <ul style="list-style-type: none"> <li>• In secondary prevention patients, the combination therapy should include a drug(s) with the appropriate compelling indications.</li> <li>• Certain classes of antihypertensive medications, specifically diuretics and CCBs, lower BP on average more than <math>\beta</math>-blockers and renin-angiotensin system (RAS) blockers in black patients when used as monotherapies.</li> <li>• In the absence of compelling indications, when BP is near goal levels, monotherapy with a diuretic or a CCB is preferred.</li> <li>• Lifestyle modifications should be initiated in all patients with hypertension, whether or not pharmacotherapy is planned.</li> <li>• ACE inhibitors or ARBs are recommended as alternative monotherapy options in the treatment of hypertension in blacks. The rationale for their lower tier monotherapy recommendation is because they have consistently achieved lesser average reductions in BP relative to that observed with monotherapy using either a diuretic or CCB.</li> </ul>
<p>Kidney Disease Improving Clinical Outcomes Group; KDIGO Clinical Practice Guideline for the Management of Blood Pressure in Chronic Kidney Disease (2021)<sup>34</sup></p>	<p><u>Blood pressure measurement</u></p> <ul style="list-style-type: none"> <li>• The Work Group recommends standardized office blood pressure (BP) measurement in preference to routine office BP measurements for the management of high BP in adults.</li> <li>• The Work Group suggests that out-of-office BP measurements with ambulatory BP monitoring (ABPM) or home BP monitoring (HBPM) be used to complement standardized office BP readings for the management of high BP.</li> </ul> <p><u>Lifestyle interventions for lowering BP in patients with chronic kidney disease (CKD) not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>• The Work Group suggests targeting a sodium intake &lt;2 grams of sodium per day (or &lt;90 mmol of sodium per day, or &lt;5 grams of sodium chloride per day) in patients with high BP and CKD.</li> <li>• The Work Group suggests that patients with high BP and CKD be advised to undertake moderate-intensity physical activity for a cumulative duration of at least 150 minutes per week, or to a level compatible with their cardiovascular and physical tolerance.</li> </ul> <p><u>BP management in patients with CKD, with or without diabetes, not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>• The Work Group suggests that adults with high BP and CKD be treated with a target systolic BP (SBP) of &lt;120 mmHg, when tolerated, using standardized office BP measurement.</li> <li>• The Work Group recommends starting renin-angiotensin-system inhibitors (RASi) (angiotensin-converting enzyme inhibitor [ACEi] or angiotensin II receptor blocker [ARB]) for people with high BP, CKD, and severely increased albuminuria without diabetes.</li> <li>• The Work Group suggests starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately increased albuminuria without diabetes.</li> <li>• The Work Group recommends starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately-to-severely increased albuminuria with diabetes.</li> <li>• The Work Group recommends avoiding any combination of ACEi, ARB, and direct renin inhibitor (DRI) therapy in patients with CKD, with or without diabetes.</li> </ul> <p><u>BP management in kidney transplant recipients</u></p> <ul style="list-style-type: none"> <li>• Treat adult kidney transplant recipients with high BP to a target BP of &lt;130 mmHg systolic and &lt;80 mmHg diastolic using standardized office BP measurement.</li> <li>• The Work Group recommends that a dihydropyridine calcium channel blocker (CCB) or an ARB be used as the first-line antihypertensive agent in adult kidney</li> </ul>

Clinical Guideline	Recommendations
	<p><b>transplant recipients.</b></p> <p><b>BP management in children with CKD</b></p> <ul style="list-style-type: none"> <li>The Work Group suggests that in children with CKD, 24-hour mean arterial pressure by ABPM should be lowered to &lt;50<sup>th</sup> percentile for age, sex, and height.</li> </ul>
<p>American College of Cardiology/ American Heart Association Task Force: <b>Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults (2017)</b><sup>35</sup></p>	<p><u>Initiation of Blood Pressure (BP) Treatment for Overall Cardiovascular Disease (CVD) Risk</u></p> <ul style="list-style-type: none"> <li>Use of BP-lowering medications is recommended for secondary prevention of recurrent CVD events in patients with clinical CVD and an average systolic blood pressure (SBP) <math>\geq 130</math> mmHg or an average diastolic blood pressure (DBP) of <math>\geq 80</math> mmHg and for primary prevention in adults with an estimated 10-year atherosclerotic cardiovascular disease (ASCVD) risk of <math>\geq 10\%</math> and an average SBP of <math>\geq 130</math> mmHg or an average <math>\geq 80</math> mmHg.</li> <li>Use of BP-lowering medication is recommended for primary prevention of CVD in adults with no history of CVD and with an estimated 10-year ASCVD risk <math>&lt; 10\%</math> and an SBP of <math>\geq 140</math> mmHg or a DBP of <math>\geq 90</math> mmHg.</li> <li>Simultaneous use of an angiotensin converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), and/or renin inhibitor is potentially harmful and is not recommended to treat adults with hypertension.</li> <li>For adults with confirmed hypertension and known CVD or 10-year ASCVD risk of <math>\geq 10\%</math>, a BP target <math>&lt; 130/80</math> mmHg is recommended. For adults with confirmed hypertension without additional markers of increased CVD risk, a BP target <math>&lt; 130/80</math> mmHg may be reasonable.</li> <li>For initiation of antihypertensive drug therapy, first-line agents include thiazide diuretics, calcium channel blockers (CCBs), and ACE inhibitors or ARBs.</li> <li>Initiation of antihypertensive drug therapy with two first-line agents of different classes, either as separate agents or in a fixed-dose combination, is recommended in adults with stage 2 hypertension and an average BP <math>&gt; 20/10</math> mmHg above their BP target.</li> <li>Initiation of antihypertensive drug therapy with a single antihypertensive drug is reasonable in adults with stage 1 hypertension and BP goal <math>&lt; 130/80</math> mmHg with dosage titration and sequential addition of other agents to achieve the BP target.</li> </ul> <p><u>Stable Ischemic Heart Disease (SIHD)</u></p> <ul style="list-style-type: none"> <li>In adults with SIHD and hypertension, a BP target <math>&lt; 130/80</math> is recommended.</li> <li>Adults with SIHD and hypertension (BP <math>\geq 130/80</math> mmHg) should be treated with medications [e.g., guideline-directed medical therapy (GDMT) beta-blockers, ACE inhibitors, or ARBs] for compelling indications [e.g., previous myocardial infarction (MI), stable angina] as first-line therapy, with the addition of other drugs (e.g., dihydropyridine CCBs, thiazide diuretics, and/or mineralocorticoid receptor antagonists) as needed to further control hypertension.</li> <li>In adults with SIHD with angina and persistent uncontrolled hypertension, the addition of dihydropyridine CCBs to GDMT beta-blockers is recommended.</li> <li>In adults who have had a MI or acute coronary syndrome, it is reasonable to continue GDMT beta-blockers beyond three years as long-term therapy for hypertension.</li> <li>Beta-blockers and/or CCBs might be considered to control hypertension in patients with coronary artery disease (CAD) had an MI more than three years ago and have angina.</li> </ul> <p><u>Heart Failure</u></p> <ul style="list-style-type: none"> <li>In adults with increased risk of HF, the optimal BP in those with hypertension should be <math>&lt; 130</math> mmHg.</li> <li>Adults with HFrEF and hypertension should be prescribed GDMT titrated to attain a BP <math>&lt; 130/80</math> mmHg.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Non-dihydropyridine CCBs are not recommended in the treatment of hypertension in adults with HFpEF.</li> <li>• In adults with HFpEF who present with symptoms of volume overload, diuretics should be prescribed to control hypertension.</li> <li>• Adults with HFpEF and persistent hypertension after management of volume overload should be prescribed ACE inhibitors or ARBs and beta-blockers titrated to attain SBP &lt;130 mmHg.</li> </ul> <p><u>CKD</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and CKD should be treated to a BP goal &lt;130/80 mmHg.</li> <li>• In adults with hypertension and CKD [stage 3 or higher or stage 1 or 2 with albuminuria (<math>\geq 300</math> mg/d, or <math>\geq 300</math> mg/g albumin-to-creatinine ratio or the equivalent in the first morning void)], treatment with an ACE inhibitor is reasonable to slow kidney disease progression. Treatment with an ARB may be reasonable if an ACE inhibitor is not tolerated.</li> <li>• After kidney transplantation, it is reasonable to treat patients with hypertension to a BP goal &lt;130/80 mmHg and with a CCB on the basis of improved glomerular filtration rate (GFR) and kidney survival.</li> </ul> <p><u>Cerebrovascular Disease</u></p> <ul style="list-style-type: none"> <li>• In adults with intracerebral hemorrhage (ICH) who present with SBP &gt;220 mmHg, it is reasonable to use continuous intravenous (IV) drug infusion and close BP monitoring to lower levels. Immediate lowering of SBP to &lt;140 mmHg in adults with spontaneous ICH who present within six hours of the acute event and have an SBP between 150 mmHg and 220 mmHg is not of benefit to reduce death or severe disability and can be potentially harmful.</li> <li>• Adults with acute ischemic stroke and elevated BP who are eligible for treatment with IV tissue plasminogen activator (tPA) should have their BP slowly lowered to &lt;185/110 mmHg before thrombolytic therapy is initiated.</li> <li>• In adults with an acute ischemic stroke, BP should be &lt;185/110 mmHg before administration of IV tPA and should be maintained below 180/105 mmHg for at least the first 24 hours after initiation drug therapy.</li> <li>• Starting or restarting antihypertensive therapy during hospitalization in patients with BP &gt;140/90 mmHg who are neurologically stable is safe and reasonable to improve long-term BP control, unless contraindicated.</li> <li>• In patient with BP <math>\geq 220/120</math> mmHg who did not receive IV alteplase or endovascular treatment and have no comorbid conditions requiring acute antihypertensive treatment, the benefit of initiating or reinitiating treatment of hypertension within the first 48 to 72 hours is uncertain. It might be reasonable to lower BP by 15% during the first 24 hours after onset of stroke. In patients with BP &lt;220/120 mmHg with the same conditions, initiating or reinitiating treatment of hypertension within the first 48 to 72 hours after an acute ischemic stroke is not effective to prevent death or dependency.</li> <li>• Adults with previously treated stroke or transient ischemic attack should be restarted on antihypertensive treatment after the first few days of the index event to reduce the risk of recurrent stroke and other vascular events. Treatment with a thiazide diuretic, ACE inhibitor, or ARB, or combination treatment consisting of a thiazide diuretic plus ACE inhibitor, is useful.</li> <li>• Adults not previously treated for hypertension who experienced a stroke or transient ischemic attack and have an established BP <math>\geq 140/90</math> mmHg should be prescribed antihypertensive treatment a few days after the index event to reduce the risk of recurrent stroke and other vascular event.</li> <li>• For adults who experience a stroke or transient ischemic attack, selection of specific drugs should be individualized on the basis of patient comorbidities and agent pharmacological class.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• For adults who experience a stroke or transient ischemic attack, a BP goal &lt;130/80 mmHg may be reasonable.</li> <li>• For adults with a lacunar stroke, a target SBP goal &lt;130 mmHg may be reasonable.</li> <li>• In adults previously untreated for hypertension who experience an ischemic stroke or transient ischemic attack and have an SBP &lt;140 mmHg and a DBP &lt;90 mmHg, the usefulness of initiating antihypertensive treatment is not well established.</li> </ul> <p><u>Peripheral Artery Disease (PAD)</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and PAD should be treated similarly to patients with hypertension without PAD.</li> </ul> <p><u>Diabetes Mellitus (DM)</u></p> <ul style="list-style-type: none"> <li>• In adults with DM and hypertension, antihypertensive drug treatment should be initiated at a BP of <math>\geq</math>130/80 mmHg with a treatment goal &lt;130/80 mmHg.</li> <li>• In adults with DM and hypertension, all first-line classes of antihypertensive agents (i.e., diuretics, ACE inhibitors, ARBs, and CCBs) are useful and effective.</li> <li>• In adults with DM and hypertension, ACE inhibitors or ARBs may be considered in the presence of albuminuria.</li> </ul> <p><u>Atrial Fibrillation, Valvular Heart Disease, and Aortic disease</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension can be useful for prevention of recurrence of AF.</li> <li>• In adults with asymptomatic aortic stenosis, hypertension should be treated with pharmacotherapy, starting at a low dose and gradually titrating upward as needed.</li> <li>• In patients with chronic aortic insufficiency, treatment of systolic hypertension with agents that do not slow the heart rate (i.e., avoid beta-blockers) is reasonable.</li> <li>• Beta-blockers are recommended as the preferred antihypertensive agents in patients with hypertension and thoracic aortic disease.</li> </ul> <p><u>Racial and Ethnic Differences in Treatment</u></p> <ul style="list-style-type: none"> <li>• In black adults with hypertension but without HF or CKD, including those with DM, initial antihypertensive treatment should include a thiazide-type diuretic or CCB. Two or more antihypertensive medications are recommended to achieve a BP target &lt;130/80 mmHg in most adults with hypertension, especially in black adults with hypertension.</li> </ul> <p><u>Pregnancy</u></p> <ul style="list-style-type: none"> <li>• Women with hypertension who become pregnant, or are planning to become pregnant, should be transitioned to methyldopa, nifedipine, and/or labetalol during pregnancy.</li> <li>• Women with hypertension who become pregnant should not be treated with ACE inhibitors, ARBs, or direct renin inhibitors.</li> </ul> <p><u>Older Persons</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension with an SBP treatment goal &lt;130 mmHg is recommended for noninstitutionalized ambulatory community-dwelling adults (<math>\geq</math>65 years of age) with an average SBP of <math>\geq</math>130 mmHg.</li> <li>• For older adults (<math>\geq</math>65 years of age) with hypertension and a higher burden of comorbidity and limited life expectancy, clinical judgment, patient preference, and a team-based approach to assess risk/benefit is reasonable for decisions regarding intensity of BP lowering and choice of antihypertensive drugs.</li> </ul> <p><u>Hypertensive Crises</u></p> <ul style="list-style-type: none"> <li>• In adults with a hypertensive emergency, admission to an intensive care unit is recommended for continuous monitoring of BP and target organ damage and for parenteral administration of an appropriate agent.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• For adults with a compelling condition (i.e., aortic dissection, severe pre-eclampsia or eclampsia, or pheochromocytoma crisis), SBP should be reduced to &lt;140 mmHg during the first hour and to &lt;120 mmHg in aortic dissection.</li> <li>• For adults without a compelling condition, SBP should be reduced by no more than 25% within the first hours; then, if stable, to 160/100 mmHg within the next two to six hours; and then cautiously to normal during the following 24 to 48 hours.</li> </ul> <p><u>Cognitive Decline and Dementia</u></p> <ul style="list-style-type: none"> <li>• In adults with hypertension, BP lowering is reasonable to prevent cognitive decline and dementia.</li> </ul> <p><u>Patients Undergoing Surgical Procedures</u></p> <ul style="list-style-type: none"> <li>• In patients with hypertension undergoing major surgery who have been on beta-blockers chronically, beta-blockers should be continued.</li> <li>• In patients with hypertension undergoing planned elective major surgery, it is reasonable to continue medical therapy for hypertension until surgery.</li> <li>• In patients with hypertension undergoing major surgery, discontinuation of ACE inhibitors or ARBs perioperatively may be considered.</li> <li>• In patients with planned elective major surgery and SBP ≥180 mmHg or DBP ≥110 mmHg, deferring surgery may be considered.</li> <li>• For patients undergoing surgery, abrupt pre-operative discontinuation of beta-blockers or clonidine is potentially harmful.</li> <li>• Beta-blockers should not be started on the day of surgery in beta-blocker-naïve patients.</li> <li>• Patients with intraoperative hypertension should be managed with IV medications until such time as oral medications can be resumed.</li> </ul>
<p>American Diabetes Association: <b>Standards of Medical Care in Diabetes (2022)</b><sup>36</sup></p>	<p><u>Hypertension/blood pressure control</u></p> <ul style="list-style-type: none"> <li>• Blood pressure should be measured at every routine visit. When possible, patients found to have elevated blood pressure (≥140/90) should have blood pressure confirmed using multiple readings, including measurements on a separate day, to diagnose hypertension. Patients with blood pressure ≥180/110 and cardiovascular disease could be diagnosed with hypertension at a single visit.</li> <li>• All hypertensive patients with diabetes should monitor their blood pressure at home.</li> <li>• For patients with diabetes and hypertension, with diabetes and hypertension, blood pressure targets should be individualized through a shared decision-making process that addresses cardiovascular risk, potential adverse effects of antihypertensive medications, and patient preferences.</li> <li>• For individuals with diabetes and hypertension at higher cardiovascular risk (existing atherosclerotic cardiovascular disease [ASCVD] or 10-year ASCVD risk ≥15%), a blood pressure target of &lt;130/80 mmHg may be appropriate, if it can be safely attained.</li> <li>• For individuals with diabetes and hypertension at lower risk for cardiovascular disease (10-year atherosclerotic cardiovascular disease risk &lt;15%), treat to blood pressure target of &lt;140/90.</li> <li>• In pregnant patients with diabetes and preexisting hypertension, a blood pressure target of 110 to 135/85 is suggested in the interest of reducing the risk for accelerated maternal hypertension and minimizing impaired fetal growth.</li> <li>• For patients with blood pressure &gt;120/80, lifestyle intervention consists of weight loss when indicated, a Dietary Approaches to Stop Hypertension (DASH)-style eating pattern including reducing sodium and increasing potassium intake, moderation of alcohol intake, and increased physical activity.</li> <li>• Patients with confirmed office-based blood pressure ≥140/90 mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of pharmacologic therapy to achieve blood pressure goals.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Patients with confirmed office-based blood pressure <math>\geq 160/100</math> mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of two drugs or a single pill combination of drugs demonstrated to reduce cardiovascular events in patients with diabetes.</li> <li>• Treatment for hypertension should include drug classes demonstrated to reduce cardiovascular events in patients with diabetes (ACE inhibitors, angiotensin receptor blockers, thiazide-like diuretics, or dihydropyridine calcium channel blockers). ACE inhibitors or angiotensin receptor blockers are recommended first-line therapy for hypertension in people with diabetes and coronary artery disease.</li> <li>• Multiple-drug therapy is generally required to achieve blood pressure targets (but not a combination of ACE inhibitors and angiotensin receptor blockers).</li> <li>• An ACE inhibitor or angiotensin receptor blocker, at the maximum tolerated dose indicated for blood pressure treatment, is the recommended first-line treatment for hypertension in patients with diabetes and urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine or 30 to 299 mg/g creatinine. If one class is not tolerated, the other should be substituted.</li> <li>• For patients treated with an ACE inhibitor, angiotensin receptor blocker, or diuretic, serum creatinine/estimated glomerular filtration rate and serum potassium levels should be monitored at least annually.</li> <li>• Patients with hypertension who are not meeting blood pressure targets on three classes of antihypertensive medications (including a diuretic) should be considered for mineralocorticoid receptor antagonist therapy.</li> </ul> <p><b>Chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>• At least once a year, assess urinary albumin (e.g., spot urinary albumin-to-creatinine ratio) and estimated glomerular filtration rate in patients with type 1 diabetes with duration of five or more years and in all patients with type 2 diabetes.</li> <li>• Patients with diabetes and urinary albumin <math>\geq 300</math> mg/g creatinine and/ or an estimated glomerular filtration rate 30 to 60 mL/min/1.73 m<sup>2</sup> should be monitored twice annually to guide therapy.</li> <li>• Optimize glucose control to reduce the risk or slow the progression of chronic kidney disease (CKD).</li> <li>• For patients with type 2 diabetes and diabetic kidney disease, use of a sodium-glucose cotransporter 2 inhibitor in patients with an estimated glomerular filtration rate <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> and urinary albumin <math>\geq 300</math> mg/g creatinine is recommended to reduce CKD progression and cardiovascular events.</li> <li>• In patients with type 2 diabetes and CKD, consider use of sodium-glucose cotransporter 2 inhibitors additionally for cardiovascular risk reduction when estimated glomerular filtration rate and urinary albumin creatinine are <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> or <math>\geq 300</math> mg/g, respectively.</li> <li>• In patients with CKD who are at increased risk for cardiovascular events or CKD progression and are unable to use a sodium-glucose cotransporter 2 inhibitor, a nonsteroidal mineralocorticoid receptor antagonist (finerenone) is recommended to reduce CKD progression and cardiovascular events.</li> <li>• Optimize blood pressure control and reduce blood pressure variability to reduce the risk or slow the progression of CKD.</li> <li>• Do not discontinue renin-angiotensin system blockade for minor increases in serum creatinine (<math>\leq 30\%</math>) in the absence of volume depletion.</li> <li>• For people with nondialysis-dependent stage 3 or higher CKD, dietary protein intake should be a maximum of 0.8 g/kg body weight per day (the recommended daily allowance). For patients on dialysis, higher levels of dietary protein intake should be considered, since malnutrition is a major problem in some dialysis patients.</li> <li>• In nonpregnant patients with diabetes and hypertension, either an ACE inhibitor or an angiotensin receptor blocker is recommended for those with modestly elevated</li> </ul>

Clinical Guideline	Recommendations
	<p>urinary albumin-to-creatinine ratio (30 to 299 mg/g creatinine) and is strongly recommended for those with urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine and/or estimated glomerular filtration rate <math>&lt; 60</math> mL/min/1.73 m<sup>2</sup>.</p> <ul style="list-style-type: none"> <li>Periodically monitor serum creatinine and potassium levels for the development of increased creatinine or changes in potassium when ACE inhibitors, angiotensin receptor blockers, or diuretics are used.</li> <li>An ACE inhibitor or an angiotensin receptor blocker is not recommended for the primary prevention of CKD in patients with diabetes who have normal blood pressure, normal urinary albumin-to-creatinine ratio (<math>&lt; 30</math> mg/g creatinine), and normal estimated glomerular filtration rate.</li> <li>Patients should be referred for evaluation by a nephrologist if they have an estimated glomerular filtration rate <math>&lt; 30</math> mL/min/1.73 m<sup>2</sup>.</li> <li>Promptly refer to a nephrologist for uncertainty about the etiology of kidney disease, difficult management issues, and rapidly progressing kidney disease.</li> </ul>

\*Agent not available in the United States.

### III. Indications

The Food and Drug Administration (FDA)-approved indications for the miscellaneous calcium-channel blocking agents are noted in Table 3. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 3. FDA-Approved Indications for the Calcium-Channel Blocking Agents, Miscellaneous<sup>1,2,6-14</sup>**

Indication	Diltiazem	Verapamil
<b>Angina Pectoris</b>		
Angina due to coronary artery spasm	✓ (tablet, ER capsule [Cardizem CD <sup>®</sup> ])	
Chronic stable angina	✓	✓ (tablet)
Unstable angina		✓ (tablet)
Vasospastic angina		✓ (tablet)
<b>Arrhythmias</b>		
Control of ventricular rate at rest and during stress in patients with chronic atrial flutter and/or atrial fibrillation in association with digitalis		✓ (tablet)
Prophylaxis of repetitive paroxysmal supraventricular tachycardia		✓ (tablet)
Rapid conversion to sinus rhythm of paroxysmal supraventricular tachycardias	✓ (injection)	✓ (injection)
Temporary control of rapid ventricular rate in atrial flutter or atrial fibrillation	✓ (injection)	✓ (injection)
<b>Hypertension</b>		
Hypertension	✓ * (ER)	✓

\*May be used alone or in combination with other antihypertensive agents.  
ER=extended-release

### IV. Pharmacokinetics

The pharmacokinetic parameters of the miscellaneous calcium-channel blocking agents are listed in Table 4.

**Table 4. Pharmacokinetic Parameters of the Calcium-Channel Blocking Agents, Miscellaneous<sup>2</sup>**

Generic Name(s)	Bioavailability (%)	Protein Binding (%)	Metabolism (%)	Excretion (%)	Half-Life (hours)

Diltiazem*	35 to 40	77 to 93	Liver, extensive (% not reported)	Renal (35) Feces (60 to 65)	3 to 10
Verapamil*	20 to 35	88 to 94	Liver (65 to 80)	Renal (70) Feces (9 to 16)	4 to 12

\*Immediate-release

## V. Drug Interactions

Major drug interactions with the miscellaneous calcium-channel blocking agents are listed in Table 5.

**Table 5. Major Drug Interactions with the Calcium-Channel Blocking Agents, Miscellaneous<sup>2</sup>**

Generic Name(s)	Interaction	Mechanism
Calcium-channel blocking agents, miscellaneous (diltiazem, verapamil)	Macrolides	Increased serum levels of macrolide antibiotics may result if administered with calcium-channel blocking agents, miscellaneous, due to the inhibitory effect on CYP3A4. Coadministration should be avoided.
Calcium-channel blocking agents, miscellaneous (diltiazem, verapamil)	Narcotic Analgesics	Calcium-channel blocking agents, miscellaneous may increase plasma concentrations of narcotic analgesics, increasing the potential for enhanced pharmacologic effects and toxicity. Inhibition of CYP3A4 isoenzyme by Calcium-channel blocking agents, miscellaneous may decrease the metabolic elimination of narcotic analgesics.
Calcium-channel blocking agents, miscellaneous (diltiazem, verapamil)	Vasopressin Receptor Antagonists	Plasma concentrations and pharmacologic effects of vasopressin receptor antagonists may be increased by diltiazem. Inhibition of CYP3A isoenzymes by diltiazem may decrease the metabolic elimination of vasopressin receptor antagonists.
Calcium-channel blocking agents, miscellaneous (diltiazem, verapamil)	Amiodarone	Concurrent use of amiodarone and calcium channel blockers may result in bradycardia, atrioventricular block and/or sinus arrest.
Calcium-channel blocking agents, miscellaneous (diltiazem, verapamil)	Colchicine	Plasma concentrations of colchicine may be increased. Colchicine toxicity may occur. Inhibition of CYP3A4 and/or efflux transporter P-glycoprotein diltiazem may increase the absorption and decrease the metabolic elimination of colchicine.
Calcium-channel blocking agents, miscellaneous (diltiazem, verapamil)	Carbamazepine	Increased serum levels of carbamazepine may result if administered with diltiazem, increasing the risk of greater effect and toxicity, due to inhibition of carbamazepine metabolism by diltiazem.
Calcium-channel blocking agents, miscellaneous (diltiazem, verapamil)	Cyclosporine	Increased serum levels of cyclosporine may result if administered with diltiazem, due to inhibition of cyclosporine metabolism by diltiazem.
Calcium-channel blocking agents, miscellaneous (diltiazem, verapamil)	Everolimus	Pharmacologic effects and plasma concentrations of everolimus may be increased by diltiazem. Inhibition of CYP3A4 and P-glycoprotein by diltiazem may decrease the metabolic elimination of everolimus.
Calcium-channel blocking agents, miscellaneous (diltiazem, verapamil)	Ibrutinib	Diltiazem inhibits CYP3A4 metabolism of ibrutinib, thereby increasing plasma concentrations, pharmacologic effects, and risk of toxicity (e.g., hemorrhage, renal toxicity).
Calcium-channel blocking agents, miscellaneous (diltiazem, verapamil)	Lomitapide	Diltiazem inhibits CYP3A4 metabolism of lomitapide, thereby increasing plasma concentrations, pharmacologic effects, and risk of adverse reactions, including hepatotoxicity.

Generic Name(s)	Interaction	Mechanism
Calcium-channel blocking agents, miscellaneous (diltiazem, verapamil)	Ranolazine	Increased serum levels of ranolazine may result if administered with diltiazem, due to diltiazem's inhibitory effect on CYP3A4. Coadministration should be avoided due to the increased risk of QTc prolongation, torsades de pointes arrhythmias and death.
Calcium-channel blocking agents, miscellaneous (diltiazem, verapamil)	HMG CoA reductase inhibitors	Plasma concentrations and pharmacologic effects of statins may be increased by co-administration. The risk of myopathy and rhabdomyolysis may be increased. Inhibition of CYP3A4 isoenzymes by miscellaneous calcium-channel blockers may decrease the metabolic elimination of statins.
Calcium-channel blocking agents, miscellaneous (diltiazem)	Benzodiazepines	Increased serum levels of benzodiazepines may result if administered with diltiazem, increasing the risk of central nervous system depression, due to decreased metabolism of benzodiazepines.
Calcium-channel blocking agents, miscellaneous (diltiazem)	$\beta$ -Blockers	Increased serum levels of $\beta$ -blockers may result if administered with diltiazem, increasing the risk of symptomatic bradycardia, due to decreased metabolism of $\beta$ -blockers and additive pharmacologic effects.
Calcium-channel blocking agents, miscellaneous (diltiazem)	Cilostazol	Pharmacologic effects of cilostazol may be increased by diltiazem. Elevated plasma concentrations with toxicity may occur. Inhibition of CYP3A4 isoenzymes by diltiazem may decrease the metabolic elimination of cilostazol.
Calcium-channel blocking agents, miscellaneous (diltiazem)	Cisapride	Concurrent use may result in an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest).
Calcium-channel blocking agents, miscellaneous (diltiazem)	Corticosteroids	Diltiazem may increase the pharmacologic effects of corticosteroids. Inhibition of CYP3A4 isoenzymes by diltiazem may decrease the metabolic elimination of corticosteroids.
Calcium-channel blocking agents, miscellaneous (diltiazem)	Digoxin	Increased serum levels of digoxin may result, increasing the risk of digoxin toxicity, if administered with diltiazem, due to decreased renal clearance of digoxin.
Calcium-channel blocking agents, miscellaneous (diltiazem)	HIV Protease Inhibitors	Plasma concentrations and pharmacologic effects of diltiazem may be increased by HIV protease inhibitors. An additive effect on the PR interval has also been demonstrated. Plasma concentrations and pharmacologic effects of diltiazem may be increased by HIV protease inhibitors.
Calcium-channel blocking agents, miscellaneous (diltiazem)	Macrolide immuno-suppressives	Plasma trough concentrations of macrolide immunosuppressives may be increased by diltiazem. Neurologic toxicity may occur. Diltiazem may increase the plasma trough concentrations of macrolide immunosuppressives. Neurologic toxicity may occur.
Calcium-channel blocking agents, miscellaneous (diltiazem)	Theophyllines	The pharmacologic and toxic effects of theophyllines may be increased due to the inhibition of metabolism of theophylline by diltiazem.
Calcium-channel blocking agents, miscellaneous (verapamil)	$\beta$ -Blockers	Effects of $\beta$ -blockers and diltiazem may be increased, close monitoring of cardiac function is recommended. Diltiazem may inhibit the metabolism of some $\beta$ -blockers (atenolol, metoprolol and propranolol), leading to increased effects of these $\beta$ -blockers.
Calcium-channel	Digoxin	Verapamil may alter the pharmacokinetics and increase

Generic Name(s)	Interaction	Mechanism
blocking agents, miscellaneous (verapamil)		serum concentrations of digoxin. Verapamil may decrease nonrenal and total digoxin clearance.
Calcium-channel blocking agents, miscellaneous (verapamil)	Dofetilide	Increase serum levels and effects of dofetilide may occur if coadministered with verapamil, increasing the risk of arrhythmia.
Calcium-channel blocking agents, miscellaneous (verapamil)	Quinidine	Pharmacologic effects of quinidine may be increased. This combination may produce marked hypotension. Verapamil inhibits the hepatic metabolism of quinidine.
Calcium-channel blocking agents, miscellaneous (verapamil)	Aldosterone Blockers	Verapamil may increase plasma concentrations and pharmacologic or toxic effects of aldosterone blockers. Inhibition of CYP3A4 isoenzymes by verapamil may decrease the metabolic elimination of aldosterone blockers.
Calcium-channel blocking agents, miscellaneous (verapamil)	Clonidine	Sinus bradycardia, atrioventricular block and severe hypotension may occur with coadministration of clonidine and verapamil.
Calcium-channel blocking agents, miscellaneous (verapamil)	Dronedarone	Plasma concentrations and pharmacologic effects of dronedarone may be increased by verapamil. Dronedarone may also increase the plasma concentrations and pharmacologic effects of verapamil. Additionally, verapamil may enhance the electrophysiologic effects of dronedarone.
Calcium-channel blocking agents, miscellaneous (verapamil)	Flecainide	Increased risk of cardiotoxic effects may occur when flecainide and verapamil are coadministered. Cardiogenic shock or asystole may develop. Pharmacologic effects may be additive or synergistic.
Calcium-channel blocking agents, miscellaneous (verapamil)	Nondepolarizing muscle relaxants	Increased serum levels of nondepolarizing muscle relaxants may result, increasing the risk of respiratory depression, if coadministered with verapamil, due to calcium's role on muscle contraction.
Calcium-channel blocking agents, miscellaneous (verapamil)	Quinazolines	The combination of verapamil and quinazolines may produce an acute hypotensive effect which is greater than when either drug is taken alone. Verapamil may decrease the first-pass hepatic metabolism and increase the bioavailability of quinazolines.
Calcium-channel blocking agents, miscellaneous (verapamil)	Rifampin	Decreased serum levels of verapamil may result if coadministered with rifampin, due to increased metabolism of verapamil.

CYP=cytochrome P450 isoenzymes, HIV=human immunodeficiency virus, HMG CoA=3-hydroxy-3-methyl-glutaryl-CoA

## VI. Adverse Drug Events

The most common adverse drug events reported with the miscellaneous calcium-channel blocking agents are listed in Table 6.

## VII. Dosing and Administration

The usual dosing regimens for the miscellaneous calcium-channel blocking agents are listed in Table 7.

**Table 7. Usual Dosing Regimens for the Calcium-Channel Blocking Agents, Miscellaneous<sup>1,2,6-14</sup>**

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
Diltiazem	<p><u>Angina pectoris (chronic stable):</u>            Extended-release capsule: initial, 120 mg/day; maintenance, 180 to 480 mg/day; maximum, 480 mg/day</p> <p>Extended-release tablet: initial, 180 mg once daily; maximum, 360 mg/day</p> <p>Tablet: initial, 30 mg four times daily; maintenance, 180 to 360 mg/day</p> <p><u>Angina pectoris (due to coronary artery spasm):</u>            Extended-release capsule (Cardizem CD<sup>®</sup>): initial, 120 or 180 mg once daily; maintenance, adjust dosage to each patient's needs</p> <p>Tablet: initial, 30 mg four times daily; maintenance, 180 to 360 mg/day</p> <p><u>Arrhythmias:</u>            Injection: weight based dosing administered intravenously</p> <p><u>Hypertension:</u>            Extended-release capsule: initial, 180 to 240 mg once daily; maintenance, 180 to 480 mg/day; maximum, 540 mg/day</p> <p>Extended-release tablet: initial, 180 to 240 mg once daily; maintenance, 120 to 540 mg/day; maximum, 540 mg/day</p>	Safety and efficacy in children have not been established.	<p>Extended-release capsule:            60 mg            90 mg            120 mg            180 mg            240 mg            300 mg            360 mg            420 mg</p> <p>Extended-release tablet:            120 mg            180 mg            240 mg            300 mg            360 mg            420 mg</p> <p>Injection:            5 mg/mL            100 mg</p> <p>Tablet:            30 mg            60 mg            90 mg            120 mg</p>

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
Verapamil	<p><u>Angina pectoris (chronic stable, unstable, and vasospastic):</u>            Tablet: maintenance, 80 to 120 mg three times a day</p> <p><u>Arrhythmias:</u>            Injection: weight based dosing administered by slow intravenous injection</p> <p>Tablet: maintenance, 240 to 480 mg/day, divided (three to four times daily)</p> <p><u>Hypertension:</u>            Tablet: initial, 80 mg three times daily; maintenance, 360 to 480 mg/day divided (three to four times daily); maximum, 480 mg/day</p> <p>Extended-release tablet: maintenance, 180 to 480 mg/day</p>	<p>Safety and efficacy of oral verapamil in children have not been established.</p> <p><u>Arrhythmias in children 0 to 15 years of age:</u>            Injection: weight based dosing administered by slow intravenous injection</p>	<p>Extended-release capsule            100 mg            120 mg            180 mg            200 mg            240 mg            300 mg            360 mg</p> <p>Extended-release tablet:            120 mg            180 mg            240 mg</p> <p>Injection:            2.5 mg/mL</p> <p>Tablet:            40 mg            80 mg            120 mg</p>

**VIII. Effectiveness**

Clinical studies evaluating the safety and efficacy of the miscellaneous calcium-channel blocking agents are summarized in Table 8.

**Table 8. Comparative Clinical Trials with the Calcium-Channel Blocking Agents, Miscellaneous**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<b>Angina</b>				
<p>De Rosa et al.<sup>37</sup> (1998)</p> <p>Diltiazem SR 300 mg QD</p> <p>vs</p> <p>verapamil SR 240 mg QD</p>	<p>DB, XO</p> <p>Men and women 48 to 72 years of age, with stable exertional angina, a positive test for myocardial ischemia and documented coronary artery disease</p>	<p>N=20</p> <p>12 weeks</p>	<p>Primary: Exercise tolerance test: time to onset of angina, time to 1-mm ST-segment depression and total exercise duration</p> <p>Secondary: Heart rate, angina frequency, nitroglycerin use and adverse events</p>	<p>Primary: Time to onset of angina increased significantly in both groups compared to the placebo group (verapamil vs placebo; P&lt;0.05 and diltiazem vs placebo; P&lt;0.005).</p> <p>Time to 1-mm ST-segment depression increased significantly in both groups compared to the placebo group (verapamil vs placebo; P&lt;0.05 and diltiazem vs placebo; P&lt;0.005).</p> <p>Total exercise duration increased significantly in both groups compared to the placebo group (verapamil vs placebo; P&lt;0.05 and diltiazem vs placebo; P&lt;0.005).</p> <p>For each primary endpoint, there was no significant difference between the treatment groups.</p> <p>Secondary: Heart rates were similar between the treatment groups, except resting heart rate was significantly lower in the diltiazem group as compared to the verapamil group (68.5 vs 75.9; P&lt;0.05).</p> <p>Angina frequency and nitroglycerin use decreased significantly in the diltiazem group compared to the placebo group (P&lt;0.05) and to the verapamil group (P&lt;0.05).</p> <p>Edema and flushing were most frequently reported. Similar rates of adverse events were reported for both treatments.</p>
<p>Chugh et al.<sup>38</sup> (2001)</p> <p>Diltiazem 240 mg</p>	<p>DB, DD, PG, RCT</p> <p>Patients with stable angina, blood</p>	<p>N=67</p> <p>4 weeks</p>	<p>Primary: Treadmill exercise test: time to onset of angina, time to</p>	<p>Primary: Both treatment groups, and all doses, had significant increases in time to onset of angina from baseline (P&lt;0.001 for all). There was no significant difference between the treatment groups (P=0.838) and between dose</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>QD for 2 weeks then 360 mg QD for 2 weeks</p> <p>vs</p> <p>amlodipine 5 mg QD for 2 weeks then 10 mg QD for 2 weeks</p>	<p>pressure in the range of 100/60 to 170/110 mm Hg and a positive ischemic response on a treadmill test, history of angiography</p>		<p>1-mm ST-segment depression</p> <p>Secondary: Heart rate, blood pressure, number of angina episodes and use of nitrates</p>	<p>levels (P=0.144) in time to onset of angina.</p> <p>Both treatment groups, and all doses, had significant increases in time to 1-mm ST-segment depression from baseline, except the low-dose amlodipine group (P&lt;0.004, except P=0.063). There was no significant difference between the treatment groups and between dose levels (P=0.114) in time to 1-mm ST-segment depression (P=0.691).</p> <p>Secondary: There was no significant difference between the groups in heart rate at rest or maximal exercise.</p> <p>There was no significant difference between the groups in blood pressure at rest or maximal exercise, except SBP at rest was higher in the diltiazem group (137 to 143 vs 129 to 135 mm Hg; P=0.029).</p> <p>Both treatments reduced the number of angina episodes and the use of nitrates, but these results were not statistically different between the groups (P value not reported).</p>
<p>van Kesteren et al.<sup>39</sup> (1998)</p> <p>Diltiazem CR 90 to 120 mg BID</p> <p>vs</p> <p>amlodipine 5 to 10 mg QD</p>	<p>DB, MC</p> <p>Men and women 41 to 77 years of age with a history of stable angina pectoris, a positive exercise tolerance test, and positive thallium scan or positive coronary angiogram</p>	<p>N=132</p> <p>8 weeks</p>	<p>Primary: Exercise tolerance test: time to 1-mm ST-segment depression, time to onset of chest pain, time to end of exercise (exercise duration)</p> <p>Secondary: Safety</p>	<p>Primary: Diltiazem and amlodipine treatment resulted in significant increases in time to 1-mm ST-segment depression as compared to baseline (P&lt;0.0001). Treatments were not significantly different from each other (P&gt;0.05).</p> <p>Diltiazem and amlodipine treatment resulted in significant increases in time to onset of chest pain at four and eight weeks, (10 and 13% for amlodipine; P&lt;0.0001; 5 and 7% for diltiazem; P=0.009). Treatments were not significantly different from each other (P&gt;0.05).</p> <p>Amlodipine treatment resulted in a significant increase in total exercise duration as compared to baseline (P=0.0002), however the change from baseline for diltiazem was not significantly increased (P=0.43). There was no significant difference between the treatment groups at endpoint.</p> <p>Secondary: Ten patients (15.2%) in the amlodipine group and 17 patients (25.8%) in the diltiazem group reported an adverse event; two patients from the</p>

<b>Cardiovascular Outcomes</b>				
<p>Boden et al.<sup>42</sup> (2002) INTERCEPT</p> <p>Diltiazem 300 mg QD</p> <p>vs</p> <p>placebo</p>	<p>DB, MC, PG, PRO, RCT</p> <p>Patients 75 years of age and younger, with acute MI, without CHF and who received a thrombolytic agent</p>	<p>N=874</p> <p>Up to 6 months</p>	<p>Primary: Composite first-event rate of: cardiac death, nonfatal reinfarction or refractory ischemia</p> <p>Secondary: Composite of first occurrence of cardiac death, nonfatal reinfarction, recurrent ischemia, composite of cardiac death, nonfatal reinfarction, need for myocardial revascularization, safety</p>	<p>Primary: There was no significant difference between diltiazem treatment and placebo treatment in composite event rate (131 primary outcome events occurred in the placebo group and 97 occurred in the diltiazem group; P=0.07).</p> <p>Secondary: Rates of all composite nonfatal cardiac events (nonfatal reinfarction combined with refractory ischemia or all recurrent ischemia or need for revascularization) significantly favored the diltiazem group over the placebo group (P=0.05, P=0.05, P=0.03 respectively).</p> <p>Rates of cardiac death, nonfatal reinfarction, refractory ischemia and all recurrent ischemia were similar between the diltiazem group and the placebo group, however the need for revascularization favored the diltiazem group (P=0.67, P=0.47, P=0.07, P=0.07, P=0.03).</p> <p>There was no increase in rates of CHF, bleeding, cancer or cerebrovascular accidents in the diltiazem group.</p>
<p>Gibson et al.<sup>43</sup> (2000)</p>	<p>RETRO combined subgroup analysis</p>	<p>N=817</p>	<p>Primary: All cause mortality</p>	<p>Primary: Patients receiving treatment (either agent) had a 42% lower mortality rate</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
Diltiazem 60 mg QID or verapamil 120 mg TID  vs  placebo	of 2 RCT  Patients suffering acute non-Q-wave MI	12 to 18 months	Secondary: Combined cardiac events	than those receiving placebo (P=0.010).  Secondary: Patients receiving treatment (either agent) had a 31% lower event rate (death or recurrent MI) than those receiving placebo (P<0.006).
Hansson et al. <sup>44</sup> (2000) NORDIL  Diltiazem 180 to 360 mg QD  vs  conventional therapy (diuretic, β-blocker or both)	BE, MC, OL, PRO, RCT  Patients 50 to 74 years of age with DBP ≥100 mm Hg and previously untreated	N=10,881  4.5 years	Primary: Combined fatal and nonfatal stroke, fatal and nonfatal MI, other cardiovascular death  Secondary: Fatal plus nonfatal stroke and fatal plus nonfatal MI	Primary: The primary endpoint occurred in 403 of the diltiazem patients and 400 of the diuretic/β-blocker patients (RR, 1.00; 95% CI, 0.87 to 1.15; P=0.97).  Secondary: Rates of secondary endpoints were similar between the groups. Fatal plus nonfatal stroke occurred in 159 of the diltiazem patients and 196 of the diuretic/β-blocker patients (P=0.04).  Fatal plus nonfatal MI occurred in 183 of the diltiazem patients and 157 of the diuretic/β-blocker patients (P=0.17).  Other endpoints were not statistically different between the groups including cardiovascular death (P=0.41), all cardiac events (P=0.57 and congestive heart failure (P=0.42).
Pepine et al. <sup>45</sup> (2003) INVEST  Verapamil SR 240 mg/day (step 1), then add trandolapril if needed (step 2), then increase doses of both (step 3), then add HCTZ (step 4) (calcium antagonist	MC, OL, RCT  Patients with essential HTN	N=22,576  24 months	Primary: First occurrence of death (all cause), nonfatal MI or stroke  Secondary: Cardiovascular death, angina, cardiovascular hospitalization, angina, blood pressure control (SBP/DBP	Primary: At 24 months, in the calcium antagonist strategy subgroup, 81.5% of patients were taking verapamil SR, 62.9% trandolapril, and 43.7% HCTZ. In the non-calcium antagonist strategy, 77.5% of patients were taking atenolol, 60.3% HCTZ, and 52.4% trandolapril.  After a follow-up of 61,835 patient-years (mean, 2.7 years per patient), 2,269 patients had a primary outcome event with no statistically significant difference between treatment strategies (9.93% in calcium antagonist strategy vs 10.17% in non-calcium antagonist strategy; RR, 0.98; 95% CI, 0.90 to 1.16; P=0.57).  Secondary: There was no significant difference in the rate of cardiovascular death

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>strategy)</p> <p>vs</p> <p>atenolol 50 mg/day (step 1), then add HCTZ if needed (step 2), then increase doses of both (step 3), then add trandolapril (step 4) (non-calcium antagonist strategy)</p> <p>Trandolapril was recommended for all patients with heart failure, diabetes, or renal insufficiency.</p>			<p>&lt;140/90 mm Hg or &lt;130/85 mm Hg if diabetic or renal impairment), safety</p>	<p>(P=0.94) or cardiovascular hospitalization (P=0.59) between the two treatment groups.</p> <p>At 24 months, angina episodes decreased in both groups, but the mean frequency was lower in the calcium antagonist strategy group (0.77 episodes/week) compared to the non-calcium antagonist strategy group (0.88 episodes/week; P=0.02).</p> <p>Two-year blood pressure control was similar between groups. The blood pressure goals were achieved by 65.0% (systolic) and 88.5% (diastolic) of calcium antagonist strategy patients and 64.0% (systolic) and 88.1% (diastolic) of non-calcium antagonist strategy patients. A total of 71.7% of calcium antagonist strategy patients and 70.7% of non-calcium antagonist strategy patients achieved an SBP &lt;140 mm Hg and DBP &lt;90 mm Hg.</p> <p>Both regimens were generally well tolerated. Patients in the calcium antagonist strategy group reported constipation and cough more frequently than patients in the non-calcium antagonist strategy group, while non-calcium antagonist strategy patients experienced more dyspnea, lightheadedness, symptomatic bradycardia and wheezing (all were statistically significant with P≤0.05).</p>
<p>Mancia et al.<sup>46</sup> (2007) INVEST</p> <p>Verapamil SR 120 to 480 mg QD</p> <p>vs</p> <p>atenolol 25 to 200 mg QD</p>	<p>MC, open blinded endpoint, PRO, RCT</p> <p>Patients with HTN, requiring drug therapy (BP&gt;140/90 or &gt;130/80 mm Hg if diabetic or with renal impairment), and CAD</p>	<p>N=22,576</p> <p>24 months</p>	<p>Primary: Occurrence of death, nonfatal MI and nonfatal stroke</p> <p>Secondary: Blood pressure control rates</p>	<p>Primary: Rates (death, nonfatal MI and nonfatal stroke) were similar for both treatment groups (P value not reported).</p> <p>Secondary: Rates of death, MI and stroke declined as the number of office visits for which blood pressure was controlled increased (P&lt;0.001).</p>

vs  verapamil SR 240 mg and trandolapril 4 mg QD (separate entities)				
Karlberg et al. <sup>58</sup> (2000)  Trandolapril 2 mg/day  vs  verapamil 240 mg/day  vs  trandolapril and verapamil 2-180 mg/day (fixed-dose combination)	DB, MC, PRO, RCT, XO  Patients with uncomplicated primary HTN (sitting DBP between 95 and 115 mm Hg) between the ages of 20 to 80 years	N=226  2 months	Primary: Change in blood pressure and rate pressure product  Secondary: Predictive value of plasma concentrations of active renin regarding the blood pressure response to the different treatment regimens, safety	Primary: The mean fall in blood pressure was significantly greater with the combination (20/15 mm Hg; P<0.00054), as compared to trandolapril (14/11 mm Hg) or verapamil (13/11) mm Hg. The difference between verapamil and trandolapril was not significant.  Rate pressure product decreased significantly more on the combination (P<0.001) than on trandolapril or verapamil alone.  Secondary: There was a significant positive correlation between blood pressure fall and plasma concentrations of active renin (e.g., the higher the initial active renin, the better the blood pressure response to trandolapril [P<0.045 for SBP and P<0.004 for DBP]). No relationships were found for either verapamil or the combination.  All treatments were well tolerated and safe.
Van Bortel et al. <sup>59</sup> (2008)  ACE inhibitor, ARB, β-blocker, calcium channel blocker, or placebo  vs  nebivolol	MA  12 RCTs involving >25 patients with essential HTN where nebivolol 5 mg QD was compared to placebo or other active drugs for >1 month	N=2,653  Duration varied	Primary: Antihypertensive effect and tolerability  Secondary: Not reported	Primary: Overall, higher response rates were observed with nebivolol than all other antihypertensive agents combined (OR, 1.41; 95% CI, 1.15 to 1.73; P=0.001) and compared to the ACE inhibitors (OR, 1.92; 1.30 to 2.85; P=0.001), but response rates to nebivolol were similar to β-blockers (OR, 1.29; 95% CI, 0.81 to 2.04; P=0.283), calcium channel blockers (OR, 1.19; 95% CI, 0.83 to 1.70; P=0.350) and losartan (OR, 1.35; 95% CI, 0.84 to 2.15; P=0.212).  Overall, a higher percentage of patients obtained normalized blood pressure with nebivolol compared to the other antihypertensive agents combined (OR, 1.35; 95% CI, 1.07 to 1.72; P=0.012). A higher percentage

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				<p>of patient receiving nebivolol obtained normalized blood pressure compared to losartan (OR, 1.98; 95% CI, 1.24 to 3.15; P=0.004) and calcium channel blockers (OR, 1.96; 95% CI, 1.05 to 1.96; P=0.024), but not when compared to other <math>\beta</math>-blockers (OR, 1.29; 95% CI, 0.81 to 1.65; P=0.473).</p> <p>Overall, the percentage of adverse events was significantly lower with nebivolol compared to the other antihypertensive agents combined (OR, 0.59; 95% CI, 0.48 to 0.72; P&lt;0.001) and similar to placebo (OR, 1.16; 95% CI, 0.76 to 1.67; P=0.482). In comparing nebivolol to the individual treatments, nebivolol had a lower percentage of adverse events compared to losartan (OR, 0.52; 95% CI, 0.30 to 0.89; P=0.016), the other <math>\beta</math>-blockers (OR, 0.56; 95% CI, 0.36 to 0.85; P=0.007) and calcium channel blockers (OR, 0.49; 95% CI 0.33 to 0.72; P&lt;0.001), but was similar to ACE inhibitors (OR, 0.75; 95% CI 0.52 to 1.08).</p> <p>Secondary: Not reported</p>
<p>Hilleman et al.<sup>60</sup> (1999)</p> <p>Amlodipine-benazepril (fixed-dose combination)</p> <p>vs</p> <p>monotherapy (atenolol, HCTZ, captopril, enalapril, lisinopril, amlodipine, diltiazem, nifedipine, verapamil)</p>	<p>MA</p> <p>Patients with mild to moderate essential HTN</p>	<p>82 trials</p> <p><math>\geq 4</math> weeks</p>	<p>Primary: Absolute change in supine DBP from baseline</p> <p>Secondary: Percent of patients who achieved blood pressure control, safety</p>	<p>Primary: The mean absolute decrease in supine DBP ranged from 9.7 to 13.3 mm Hg with verapamil showing the greatest effect and captopril the least. When studies were weighted by sample size, amlodipine and benazepril, atenolol, lisinopril, and verapamil showed the greatest blood pressure effect.</p> <p>Secondary: The average percentage of patients defined as controlled after treatment varied from 53.5 to 79.0%, with amlodipine and benazepril (74.3%) and lisinopril (79.0%) showing the highest percentage control (P=0.096).</p> <p>The incidence of adverse events ranged from 12.1 to 41.8%, with lisinopril and verapamil showing the lowest incidences (12.1% and 14.1%, respectively) and nifedipine the highest incidence. Lisinopril demonstrated significantly less overall side effects compared to nifedipine (P=0.030).</p> <p>Nifedipine demonstrated a higher withdrawal rate due to side effects compared to atenolol, HCTZ, enalapril, amlodipine, and diltiazem</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
				(P=0.002). Although amlodipine and benazepril had the lowest rate of withdrawals due to adverse events, lack of significant change was due to the low number of cohorts available for analysis.

**IX. Cost**

A "relative cost index" is provided below as a comparison of the average cost per prescription for medications within this American Hospital Formulary Service (AHFS) drug class. To differentiate the average cost per prescription from one product to another, a specific number of '\$' signs from one to five is assigned to each medication. Assignment of relative cost values is based upon current Alabama Medicaid prescription claims history and the average cost per prescription as paid at the retail pharmacy level. For branded products with little or no recent utilization data, the average cost per prescription is calculated by the average wholesale price (AWP) and the standard daily dosing per product labeling. For generic products with little or no recent utilization data, the average cost per prescription is calculated by the Alabama Medicaid maximum allowable cost (MAC) and the standard daily dosage per product labeling. Please note that the relative cost index does not factor in additional cost offsets available to the Alabama Medicaid program via pharmaceutical manufacturer rebating.

The relative cost index scale for this class is as follows:

Relative Cost Index Scale	
\$	\$0-\$30 per Rx
\$\$	\$31-\$50 per Rx
\$\$\$	\$51-\$100 per Rx
\$\$\$\$	\$101-\$200 per Rx
\$\$\$\$\$	Over \$200 per Rx

Rx=prescription

**Table 9. Relative Cost of the Calcium-Channel Blocking Agents, Miscellaneous**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Brand Cost	Generic Cost
Diltiazem	extended-release capsule, extended-release tablet, injection, tablet	Cardizem <sup>®*</sup> , Cardizem CD <sup>®*</sup> , Cardizem LA <sup>®</sup> , Matzim LA <sup>®</sup> , Tiazac ER <sup>®*</sup>	\$\$\$	\$\$
Verapamil	extended-release capsule, extended-release tablet, injection, tablet	Calan SR <sup>®*</sup> , Verelan <sup>®*</sup> , Verelan PM <sup>®*</sup>	\$\$\$\$ to \$\$\$\$\$	\$\$\$

\*Generic is available in at least one dosage form or strength.

**X. Conclusions**

The miscellaneous calcium-channel blocking agents are approved for the treatment of angina, arrhythmias and hypertension.<sup>1,2,6-14</sup> Diltiazem and verapamil are available in a variety of modified-release delivery systems that alter their pharmacokinetic properties, including onset and duration of action.<sup>1,2</sup> Both drugs are available in a generic formulation.

There are several national and international guidelines that provide recommendations regarding the use of calcium-channel blocking agents.<sup>15-36</sup> For the treatment of chronic angina,  $\beta$ -blockers are recommended as initial therapy; however, long-acting calcium-channel blocking agents may be used if  $\beta$ -blockers are contraindicated or if additional therapy is required.<sup>15-20</sup> Calcium-channel blocking agents are recommended as initial therapy in patients

with variant/vasospastic angina.<sup>16,19</sup> Verapamil may be considered for secondary prevention of cardiovascular disease in patients with no heart failure in whom  $\beta$ -blockers are contraindicated.<sup>21</sup> Treatment options for atrial fibrillation include ventricular rate control or drug therapy to maintain sinus rhythm. The AFFIRM, RACE, and HOT CAFE trials demonstrated similar outcomes with rate control compared to rhythm control strategies.  $\beta$ -blockers and nondihydropyridine calcium-channel blocking agents are recommended for patients with persistent or permanent atrial fibrillation, either alone or in combination with digoxin.<sup>25-27</sup> For the treatment of heart failure, ACE inhibitors, ARBs, aldosterone antagonists, and isosorbide dinitrate/hydralazine are recommended as initial therapy. In general, calcium-channel blocking agents are not recommended for the routine treatment of heart failure.<sup>22-23</sup> Thiazide-type diuretics are frequently recommended as initial therapy in patients with uncomplicated hypertension.<sup>28-33</sup> According to the National Heart, Lung, and Blood Institute's Eighth Report of The Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 8), thiazide-type diuretics should be utilized first-line for most patients with hypertension, either alone or in combination with another hypertensive from a different medication class (e.g., ACE inhibitors, ARBs,  $\beta$ -blockers, calcium channel blockers).<sup>28</sup> Several guidelines consistently recommend that the selection of an antihypertensive agent be based on compelling indications for use.<sup>28-35</sup> Most patients will require more than one antihypertensive medication to achieve blood pressure goals.<sup>28-35</sup>

Clinical trials demonstrate that diltiazem and verapamil can effectively treat angina and improve blood pressure.<sup>37-41,53-61</sup> Both agents have been shown to reduce mortality and cardiovascular event rates compared to placebo.<sup>43</sup> Evidence suggests that there is no overall difference between diltiazem and verapamil compared to other antihypertensive agents ( $\beta$ -blockers, atenolol, diuretics) in reducing cardiovascular events and mortality in patients with hypertension.<sup>44-50</sup>

There is insufficient evidence to support that one brand miscellaneous calcium-channel blocking agent is safer or more efficacious than another. Formulations without a generic alternative should be managed through the medical justification portion of the prior authorization process.

Therefore, all brand miscellaneous calcium-channel blocking agents within the class reviewed are comparable to each other and to the generic products in the class (if applicable) and offer no significant clinical advantage over other alternatives in general use.

## **XI. Recommendations**

No brand miscellaneous calcium-channel blocking agent is recommended for preferred status. Alabama Medicaid should accept cost proposals from manufacturers to determine the most cost effective products and possibly designate one or more preferred brands.

**Alabama Medicaid Agency  
Pharmacy and Therapeutics Committee Meeting  
Pharmacotherapy Review of Angiotensin-Converting Enzyme Inhibitors  
AHFS Class 243204  
May 4, 2022**

**I. Overview**

The renin-angiotensin-aldosterone system (RAAS) is the most important component in the homeostatic regulation of blood pressure. Excessive activity of the RAAS may lead to hypertension, as well as fluid and electrolyte disorders. Renin catalyzes the conversion of angiotensinogen to angiotensin I. Angiotensin I is then cleaved to angiotensin II by angiotensin-converting enzyme (ACE). Angiotensin II may also be generated through other pathways (angiotensin I convertase). Angiotensin II can increase blood pressure by direct vasoconstriction, as well as through actions on the brain and autonomic nervous system. In addition, angiotensin II stimulates aldosterone synthesis from the adrenal cortex, leading to sodium and water reabsorption. Angiotensin II exerts other detrimental effects, which include ventricular hypertrophy and remodeling and myocyte apoptosis.<sup>1-2</sup>

The ACE inhibitors are approved for the treatment of diabetic nephropathy, heart failure, hypertension, and post-myocardial infarction.<sup>3-19</sup> They block the conversion of angiotensin I to angiotensin II, and also inhibit the breakdown of bradykinin, which is a potent vasodilator. However, this increase in bradykinin also leads to an increase in adverse effects, including cough.<sup>3-19</sup> The ACE inhibitors are available as single entity products, as well as in combination with hydrochlorothiazide or verapamil. Hydrochlorothiazide inhibits the reabsorption of sodium and chloride in the cortical thick ascending limb of the loop of Henle and the early distal tubules. This action leads to an increase in the urinary excretion of sodium and chloride. Verapamil dilates coronary and peripheral arteries. It also slows conduction through the AV node, and has negative inotropic and chronotropic effects.<sup>18,19</sup>

The angiotensin-converting enzyme inhibitors that are included in this review are listed in Table 1. This review encompasses all dosage forms and strengths. All of the products are available in a generic formulation. This class was last reviewed in February 2020.

**Table 1. Angiotensin-Converting Enzyme Inhibitors Included in this Review**

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
<b>Single Entity Agents</b>			
Benazepril	tablet	Lotensin®*	benazepril
Captopril	tablet	N/A	captopril
Enalapril	solution, tablet	Epaned®*, Vasotec®*	enalapril
Enalaprilat	injection^	N/A	enalaprilat dihydrate
Fosinopril	tablet	N/A	fosinopril
Lisinopril	solution, tablet	Prinivil®*, Qbrelis®, Zestril®*	lisinopril
Moexipril	tablet	N/A	moexipril
Perindopril	tablet	N/A	perindopril
Quinapril	tablet	Accupril®*	quinapril
Ramipril	capsule	Altace®*	ramipril
Trandolapril	tablet	N/A	trandolapril
<b>Combination Products</b>			
Benazepril and hydrochlorothiazide	tablet	Lotensin HCT®*	benazepril and hydrochlorothiazide
Captopril and hydrochlorothiazide	tablet	N/A	captopril and hydrochlorothiazide
Enalapril and hydrochlorothiazide	tablet	Vaseretic®*	enalapril and hydrochlorothiazide
Fosinopril and hydrochlorothiazide	tablet	N/A	fosinopril and hydrochlorothiazide

Generic Name(s)	Formulation(s)	Example Brand Name(s)	Current PDL Agent(s)
Lisinopril and hydrochlorothiazide	tablet	Prinzide <sup>®*</sup> , Zestoretic <sup>®*</sup>	lisinopril and hydrochlorothiazide
Quinapril and hydrochlorothiazide	tablet	Accuretic <sup>®*</sup>	quinapril and hydrochlorothiazide

\*Generic is available in at least one dosage form or strength.

^Product is primarily administered in an institution.

PDL=Preferred Drug List

N/A=Not available

## II. Evidence-Based Medicine and Current Treatment Guidelines

Current treatment guidelines that incorporate the use of the angiotensin-converting enzyme inhibitors are summarized in Table 2.

**Table 2. Treatment Guidelines Using the Angiotensin-Converting Enzyme Inhibitors**

Clinical Guideline	Recommendations
American College of Cardiology/American Heart Association: <b>2007 Chronic Angina Focused Update of the 2002 Guidelines for the Management of Patients With Chronic Stable Angina (2007)</b> <sup>20</sup>	<ul style="list-style-type: none"> <li>Aspirin should be started at 75 to 162 mg/day and continued indefinitely in all patients, unless contraindicated.</li> <li>Use of warfarin in conjunction with aspirin and/or clopidogrel is associated with an increased risk of bleeding and should be monitored closely.</li> <li>Patients with hypertension and established coronary artery disease (CAD) should be treated with blood pressure medication(s) as tolerated, including angiotensin-converting enzyme inhibitors (ACE inhibitors) and/or <math>\beta</math>-adrenergic antagonists (<math>\beta</math>-blockers) with the addition of other medications as needed to achieve blood pressure goals of &lt;140/90 or &lt;130/80 mm Hg for patients with chronic kidney disease or diabetes.</li> <li>Long-acting calcium-channel blocking agents or long-acting nitrates may be used if <math>\beta</math>-blockers are contraindicated. Immediate-release and short-acting dihydropyridine calcium channel blockers can increase adverse cardiac events and should not be used.</li> <li>Long-acting calcium channel blockers or long-acting nitrates may be used with <math>\beta</math>-blockers if initial treatment is not successful.</li> <li>ACE inhibitors should be used indefinitely in patients with a left ventricular ejection fraction (LVEF) of <math>\leq 40\%</math> and in those with hypertension, diabetes or chronic kidney disease, unless contraindicated.</li> <li>ACE inhibitors should also be used indefinitely in patients at lower risk (mildly reduced or normal LVEF in whom cardiovascular risk factors remain well controlled and revascularization has been performed), unless contraindicated.</li> <li>Angiotensin II receptor blockers (ARBs) are recommended in patients with hypertension, those who have an indication for an ACE inhibitor and are intolerant to them, who have heart failure, or who have had a myocardial infarction (MI) and have a LVEF of <math>\leq 40\%</math>.</li> <li>ARBs may be considered in combination with an ACE inhibitor for heart failure due to left ventricular systolic dysfunction.</li> <li>Aldosterone blockade is recommended in patients post-MI without significant renal dysfunction or hyperkalemia who are already receiving therapeutic doses of an ACE inhibitor and a <math>\beta</math>-blocker, have a LVEF <math>\leq 40\%</math> and have either diabetes or heart failure.</li> <li>It is beneficial to start and continue <math>\beta</math>-blocker therapy indefinitely in all patients who have had a MI, acute coronary syndrome or left ventricular dysfunction with or without heart failure symptoms, unless contraindicated.</li> <li>Annual influenza vaccination is recommended in patients with cardiovascular disease.</li> </ul>
European Society of Cardiology:	<p><b>Pharmacological management of stable coronary artery disease (CAD) patients</b></p> <ul style="list-style-type: none"> <li>The two aims of the pharmacological management of stable CAD patients are to</li> </ul>

Clinical Guideline	Recommendations
<p><b>Guidelines for the Diagnosis and Management of Chronic Coronary Syndromes (2019)<sup>21</sup></b></p>	<p>obtain relief of symptoms and to prevent CV events.</p> <ul style="list-style-type: none"> <li>• Optimal medical treatment indicates at least one drug for angina/ischemia relief plus drugs for event prevention.</li> <li>• It is recommended to educate patients about the disease, risk factors and treatment strategy.</li> <li>• It is indicated to review the patient's response soon after starting therapy.</li> <li>• Concomitant use of a proton pump inhibitor is recommended in patients receiving aspirin monotherapy, DAPT, or DOAC monotherapy who are at high risk of gastrointestinal bleeding.</li> <li>• Lipid-lowering drugs: if goals are not met on maximum tolerated dose of a statin, consideration of combination therapy with ezetimibe or a PCSK9 inhibitor is recommended</li> <li>• ACE inhibitors should be considered in patients at a very high risk of cardiovascular adverse events</li> <li>• Angina/ischemia relief: <ul style="list-style-type: none"> <li>○ Short-acting nitrates are recommended.</li> <li>○ First-line treatment is indicated with <math>\beta</math>-blockers and/or calcium channel blockers to control heart rate and symptoms.</li> <li>○ Long-acting nitrates should be considered as a second-line treatment option when initial therapy with a beta-blocker and/or a non-DHP-calcium channel blocker is contraindicated, poorly tolerated, or inadequate in controlling angina symptoms</li> <li>○ Nicorandil, ranolazine, ivabradine, or trimetazidine should be considered as a second-line treatment to reduce angina frequency and improve exercise tolerance in subjects who cannot tolerate, have contraindications to, or whose symptoms are not adequately controlled by beta-blockers, CCBs, and long-acting nitrates.</li> <li>○ According to comorbidities/tolerance, it is indicated to use second-line therapies as first-line treatment in selected patients.</li> <li>○ In asymptomatic patients with large areas of ischemia (&gt;10%) <math>\beta</math>-blockers should be considered.</li> <li>○ In patients with vasospastic angina, calcium channel blockers and nitrates should be considered and beta-blockers avoided.</li> </ul> </li> <li>• Event prevention: <ul style="list-style-type: none"> <li>○ Low-dose aspirin daily is recommended in all stable CAD patients.</li> <li>○ Clopidogrel is indicated as an alternative in case of aspirin intolerance.</li> <li>○ Statins are recommended in all stable CAD patients.</li> <li>○ It is recommended to use ACE inhibitors (or ARBs) if presence of other conditions (e.g., heart failure, hypertension or diabetes).</li> </ul> </li> </ul> <p><u>Treatment in patients with microvascular angina</u></p> <ul style="list-style-type: none"> <li>• It is recommended that all patients receive secondary prevention medications including aspirin and statins.</li> <li>• <math>\beta</math>-blockers are recommended as a first-line treatment.</li> <li>• Calcium antagonists are recommended if <math>\beta</math>-blockers do not achieve sufficient symptomatic benefit or are not tolerated.</li> <li>• ACE inhibitors or nicorandil may be considered in patients with refractory symptoms.</li> <li>• Xanthine derivatives or nonpharmacological treatments such as neurostimulatory techniques may be considered in patients with symptoms refractory to the above listed drugs.</li> </ul> <p><u>Stenting and peri-procedural antiplatelet strategies in stable CAD patients</u></p> <ul style="list-style-type: none"> <li>• Drug-eluting stent (DES) is recommended in stable CAD patients undergoing stenting if there is no contraindication to prolonged dual antiplatelet therapy</li> </ul>

Clinical Guideline	Recommendations
	<p>(DAPT).</p> <ul style="list-style-type: none"> <li>• Aspirin is recommended for elective stenting.</li> <li>• Clopidogrel is recommended for elective stenting.</li> <li>• Prasugrel or ticagrelor should be considered in patients with stent thrombosis on clopidogrel without treatment interruption.</li> <li>• GP IIb/IIIa antagonists should be considered for bailout situation only.</li> <li>• Platelet function testing or genetic testing may be considered in specific or high-risk situations (e.g., prior history of stent thrombosis; compliance issue; suspicion of resistance; high bleeding risk) if results may change the treatment strategy.</li> <li>• Prasugrel or ticagrelor may be considered in specific high-risk situations of elective stenting (e.g., left main stenting, high risk of stent thrombosis, diabetes).</li> <li>• Pretreatment with clopidogrel (when coronary anatomy is not known) is not recommended.</li> <li>• Routine platelet function testing (clopidogrel and aspirin) to adjust antiplatelet therapy before or after elective stenting is not recommended.</li> <li>• Prasugrel or ticagrelor is not recommended in low-risk elective stenting.</li> <li>• After uncomplicated PCI, early cessation (<math>\leq 1</math> week) of aspirin, and continuation of dual therapy with oral anticoagulation therapy and clopidogrel should be considered if the risk of stent thrombosis is low.</li> <li>• Triple therapy with aspirin, clopidogrel, and a DOAC for <math>\geq 1</math> month should be considered when the risk of stent thrombosis outweighs the bleeding risk, with a total of no more than six months.</li> </ul> <p><u>Follow-up of revascularized stable coronary artery disease patients</u></p> <ul style="list-style-type: none"> <li>• It is recommended that all revascularized patients receive a secondary prevention and be scheduled for follow-up visit.</li> <li>• It is recommended to instruct patients before discharge about return to work and resumption of full activities. Patients have to be advised to seek immediate medical contact if symptoms (re-) occur.</li> <li>• Single antiplatelet therapy, usually aspirin, is recommended indefinitely.</li> <li>• DAPT is indicated after bare metal stent (BMS) for at least one month.</li> <li>• DAPT is indicated for six to 12 months after second generation DES.</li> <li>• DAPT may be used for more than one year in patients at high ischemic risk (e.g., stent thrombosis, recurrent acute coronary syndrome on DAPT, post MI/diffuse CAD) and low bleeding risk.</li> <li>• DAPT for one to three months may be used after DES implantation in patients at high bleeding risk or with undeferrable surgery or concomitant anticoagulant treatment.</li> </ul> <p><u>Antithrombotic therapy in patients with chronic coronary syndrome:</u></p> <ul style="list-style-type: none"> <li>• Addition of a second antithrombotic drug to aspirin for long-term secondary prevention should be considered in patients with at least a moderately increased risk of ischemic events and without high bleeding risk.</li> <li>• When oral anticoagulation is initiated in patients with AF, a DOAC is recommended in preference to VKA therapy.</li> </ul>
<p>American College of Physicians/ American College of Cardiology Foundation/ American Heart Association/ American Association for Thoracic Surgery/ Preventive Cardiovascular Nurses Association/ Society</p>	<p><u>Medical therapy to prevent MI and death in patients with stable IHD</u></p> <ul style="list-style-type: none"> <li>• Aspirin 75 to 162 mg daily should be continued indefinitely in the absence of contraindications.</li> <li>• Treatment with clopidogrel is a reasonable option when aspirin is contraindicated.</li> <li>• Dipyridamole should not be used as antiplatelet therapy.</li> <li>• Beta-blocker therapy should be initiated and continued for three years in all patients with normal left ventricular (LV) function following MI or acute coronary syndromes.</li> <li>• Metoprolol succinate, carvedilol, or bisoprolol should be used for all patients</li> </ul>

Clinical Guideline	Recommendations
<p>of Thoracic Surgeons: <b>Management of Stable Ischemic Heart Disease (2012)</b><sup>22</sup></p>	<p>with systolic LV dysfunction (ejection fraction <math>\leq 40\%</math>) with heart failure or prior MI, unless contraindicated.</p> <ul style="list-style-type: none"> <li>• ACE inhibitors should be prescribed in all patients with stable IHD who also have hypertension, diabetes, LV systolic dysfunction (ejection fraction <math>\leq 40\%</math>), and/or chronic kidney disease, unless contraindicated.</li> <li>• Angiotensin-receptor blockers (ARBs) are recommended for patients with stable IHD who have hypertension, diabetes, LV systolic dysfunction, or chronic kidney disease and have indications for, but are intolerant of, ACE inhibitors.</li> <li>• Patients should receive an annual influenza vaccine.</li> </ul> <p><u>Medical therapy for relief of symptoms in patients with stable IHD</u></p> <ul style="list-style-type: none"> <li>• Beta-blockers are recommended as initial therapy for relief of symptoms.</li> <li>• Calcium channel blockers or long-acting nitrates should be prescribed for relief of symptoms when <math>\beta</math>-blockers are contraindicated or cause unacceptable side effects.</li> <li>• Calcium channel blockers or long-acting nitrates, in combination with <math>\beta</math>-blockers, should be prescribed for relief of symptoms when initial treatment with <math>\beta</math>-blockers is unsuccessful.</li> <li>• Nitroglycerin or nitroglycerin spray should be used for immediate relief of angina.</li> <li>• Ranolazine is a fourth-line agent reserved for patients who have contraindications to, do not respond to, or cannot tolerate <math>\beta</math>-blockers, calcium-channel blockers, or long-acting nitrates.</li> </ul>
<p>American College of Cardiology Foundation/American Heart Association: <b>2014 American Heart Association/ American College of Cardiology Foundation Guideline for the Management of Patients With Non-ST-Elevation Acute Coronary Syndromes (2014)</b><sup>23</sup></p>	<p><u>Early hospital care- standard medical therapies</u></p> <ul style="list-style-type: none"> <li>• Supplemental oxygen should be administered to patients with non-ST-elevation acute coronary syndrome (NSTEMI-ACS) with arterial oxygen saturation <math>&lt; 90\%</math>, respiratory distress, or other high risk features of hypoxemia.</li> <li>• Anti-ischemic and analgesic medications             <ul style="list-style-type: none"> <li>○ Nitrates                 <ul style="list-style-type: none"> <li>▪ Patients with NSTEMI-ACS with continuing ischemic pain should receive sublingual nitroglycerin (0.3 to 0.4 mg) every 5 minutes for up to three doses, after which an assessment should be made about the need for intravenous nitroglycerin.</li> <li>▪ Intravenous nitroglycerin is indicated for patients with NSTEMI-ACS for the treatment of persistent ischemia, heart failure, or hypertension.</li> <li>▪ Nitrates should not be administered to patients who recently received a phosphodiesterase inhibitor, especially within 24 hours of sildenafil or vardenafil, or within 48 hours of tadalafil.</li> </ul> </li> <li>○ Analgesic therapy                 <ul style="list-style-type: none"> <li>▪ In the absence of contraindications, it may be reasonable to administer morphine sulphate intravenously to patients with NSTEMI-ACS if there is continued ischemic chest pain despite treatment with maximally tolerated anti-ischemic medications.</li> <li>▪ Nonsteroidal anti-inflammatory drugs (NSAIDs) (except aspirin) should not be initiated and should be discontinued during hospitalization due to the increased risk of major adverse cardiac event associated with their use</li> </ul> </li> <li>○ Beta-adrenergic blockers                 <ul style="list-style-type: none"> <li>▪ Oral <math>\beta</math>-blocker therapy should be initiated within the first 24 hours in patients who do not have any of the following: 1) signs of HF, 2) evidence of low-output state, 3) increased risk for cardiogenic shock, or 4) other contraindications to <math>\beta</math>-blockade (e.g., PR interval <math>&gt; 0.24</math> second, second- or third-degree heart block without a cardiac pacemaker, active asthma, or reactive airway disease)</li> <li>▪ In patients with concomitant NSTEMI-ACS, stabilized heart failure, and reduced systolic function, it is recommended to continue <math>\beta</math>-blocker</li> </ul> </li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>therapy with one of the three drugs proven to reduce mortality in patients with heart failure: sustained-release metoprolol succinate, carvedilol, or bisoprolol.</p> <ul style="list-style-type: none"> <li>▪ Patients with documented contraindications to <math>\beta</math>-blockers in the first 24 hours should be re-evaluated to determine subsequent eligibility.</li> </ul> <ul style="list-style-type: none"> <li>○ Calcium channel blockers (CCBs) <ul style="list-style-type: none"> <li>▪ In patients with NSTEMI-ACS, continuing or frequently recurring ischemia, and a contraindication to <math>\beta</math>-blockers, a nondihydropyridine CCB (e.g., verapamil or diltiazem) should be given as initial therapy in the absence of clinically significant LV dysfunction, increased risk for cardiogenic shock, PR interval <math>&gt;0.24</math> seconds, or second or third degree atrioventricular block without a cardiac pacemaker.</li> <li>▪ Oral nondihydropyridine calcium antagonists are recommended in patients with NSTEMI-ACS who have recurrent ischemia in the absence of contraindications, after appropriate use of <math>\beta</math>-blockers and nitrates.</li> <li>▪ CCBs are recommended for ischemic symptoms when <math>\beta</math>-blockers are not successful, are contraindicated, or cause unacceptable side effects.</li> <li>▪ Long-acting CCBs and nitrates are recommended in patients with coronary artery spasm.</li> <li>▪ Immediate-release nifedipine should not be administered to patients with NSTEMI-ACS in the absence of <math>\beta</math>-blocker therapy.</li> </ul> </li> <li>○ Other anti-ischemic interventions <ul style="list-style-type: none"> <li>▪ Ranolazine is currently indicated for treatment of chronic angina; however, it may also improve outcomes in NSTEMI-ACS patients due to a reduction in recurrent ischemia.</li> </ul> </li> <li>○ Cholesterol management <ul style="list-style-type: none"> <li>▪ High-intensity statin therapy should be initiated or continued in all patients with NSTEMI-ACS and no contraindications to its use. Treatment with statins reduces the rate of recurrent MI, coronary heart disease mortality, need for myocardial revascularization, and stroke.</li> <li>▪ It is reasonable to obtain a fasting lipid profile in patients with NSTEMI-ACS, preferably within 24 hours of presentation.</li> </ul> </li> </ul> <ul style="list-style-type: none"> <li>• Inhibitors of renin-angiotensin-aldosterone system <ul style="list-style-type: none"> <li>○ ACE inhibitors should be started and continued indefinitely in all patients with LVEF <math>&lt;0.40</math> and in those with hypertension, diabetes mellitus, or stable CKD, unless contraindicated.</li> <li>○ ARBs are recommended in patients with heart failure or myocardial infarction with LVEF <math>&lt;0.40</math> who are ACE inhibitor intolerant.</li> <li>○ Aldosterone-blockade is recommended in patients post-MI without significant renal dysfunction (creatinine <math>&gt;2.5</math> mg/dL in men or <math>&gt;2.0</math> mg/dL in women) or hyperkalemia (<math>K &gt;5.0</math> mEq/L) who are receiving therapeutic doses of ACE inhibitor and <math>\beta</math>-blocker and have a LVEF <math>&lt;0.40</math>, diabetes mellitus, or heart failure.</li> </ul> </li> <li>• Initial antiplatelet/anticoagulant therapy in patients with definite or likely NSTEMI-ACS treated with an initial invasive or ischemia-guided strategy <ul style="list-style-type: none"> <li>○ Non-enteric coated, chewable aspirin (162 to 325 mg) should be given to all patients with NSTEMI-ACS without contraindications as soon as possible after presentation, and a maintenance dose of aspirin (81 to 162 mg/day) should be continued indefinitely.</li> <li>○ In patients who are unable to take aspirin because of hypersensitivity or major gastrointestinal intolerance, a loading dose of clopidogrel followed by a daily maintenance dose should be administered.</li> <li>○ A P2Y<sub>12</sub> receptor inhibitor (clopidogrel or ticagrelor) in addition to aspirin should be administered for up to 12 months to all patients with NSTEMI-ACS without contraindications who are treated with an early invasive or ischemia-guided strategy. Options include:</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>▪ Clopidogrel: 300 or 600 mg loading dose, then 75 mg daily.</li> <li>▪ Ticagrelor: 180 mg loading dose, then 90 mg twice daily.</li> <li>▪ It is reasonable to use ticagrelor in preference to clopidogrel for P2Y<sub>12</sub> treatment in patients with NSTEMI-ACS who undergo an early invasive or ischemia-guided strategy.</li> <li>▪ In patients with NSTEMI-ACS treated with an early invasive strategy and dual antiplatelet therapy (DAPT) with intermediate/high-risk features (e.g., positive troponin), a GP IIb/IIIa inhibitor may be considered as part of initial antiplatelet therapy. Preferred options are eptifibatid or tirofiban.</li> </ul> <p><u>Percutaneous coronary intervention (PCI)- Antiplatelet and anticoagulant therapy</u></p> <ul style="list-style-type: none"> <li>• Antiplatelet agents <ul style="list-style-type: none"> <li>○ Patients already taking daily aspirin before PCI should take 81 to 325 mg non-enteric coated aspirin before PCI</li> <li>○ Patients not on aspirin therapy should be given non-enteric coated aspirin 325 mg as soon as possible before PCI.</li> <li>○ After PCI, aspirin should be continued indefinitely.</li> <li>○ A loading dose of a P2Y<sub>12</sub> inhibitor should be given before the procedure in patients undergoing PCI with stenting. Options include clopidogrel 600 mg, prasugrel 60 mg, or ticagrelor 180 mg.</li> <li>○ In patients with NSTEMI-ACS and high-risk features (e.g., elevated troponin) not adequately pretreated with clopidogrel or ticagrelor, it is useful to administer a GP IIb/IIIa inhibitor (abciximab, double-bolus eptifibatid, or high-dose bolus tirofiban) at the time of PCI.</li> <li>○ In patients receiving a stent (bare metal or drug eluting) during PCI, P2Y<sub>12</sub> inhibitor therapy should be given for at least 12 months. Options include clopidogrel 75 mg daily, prasugrel 10 mg daily, or ticagrelor 90 mg twice daily.</li> </ul> </li> <li>• Anticoagulant therapy <ul style="list-style-type: none"> <li>○ An anticoagulant should be administered to patients with NSTEMI-ACS undergoing PCI to reduce the risk of intracoronary and catheter thrombus formation.</li> <li>○ Intravenous unfractionated heparin (UFH) is useful in patients with NSTEMI-ACS undergoing PCI.</li> <li>○ Bivalirudin is useful as an anticoagulant with or without prior treatment with UFH.</li> <li>○ An additional dose of 0.3 mg/kg intravenous enoxaparin should be administered at the time of PCI to patients with NSTEMI-ACS who have received fewer than two therapeutic subcutaneous doses or received the last subcutaneous enoxaparin dose eight to 12 hours before PCI.</li> <li>○ If PCI is performed while the patient is on fondaparinux, an additional 85 IU/kg of UFH should be given intravenously immediately before PCI because of the risk of catheter thrombosis (60 IU/kg IV if a GP IIb/IIIa inhibitor used with UFH dosing based on the target-activated clotting time).</li> <li>○ Anticoagulant therapy should be discontinued after PCI unless there is a compelling reason to continue.</li> </ul> </li> <li>• Timing of CABG in relation to use of antiplatelet agents <ul style="list-style-type: none"> <li>○ Non-enteric coated aspirin (81 to 325 mg daily) should be administered preoperatively to patients undergoing CABG.</li> <li>○ In patients referred for elective CABG, clopidogrel and ticagrelor should be discontinued for at least five days before surgery and prasugrel for at least seven days before surgery.</li> <li>○ In patients referred for urgent CABG, clopidogrel and ticagrelor should be discontinued for at least 24 hours to reduce major bleeding.</li> <li>○ In patients referred for CABG, short-acting intravenous GP IIb/IIIa</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>inhibitors (eptifibatide or tirofiban) should be discontinued for at least 2 to 4 hours before surgery and abciximab for at least 12 hours before to limit blood loss and transfusion.</p> <p><u>Late hospital care, hospital discharge, and posthospital discharge care</u></p> <ul style="list-style-type: none"> <li>• Medications at discharge <ul style="list-style-type: none"> <li>○ Medications required in the hospital to control ischemia should be continued after hospital discharge in patients with NSTEMI-ACS who do not undergo coronary revascularization, patients with incomplete or unsuccessful revascularization, and patients with recurrent symptoms after revascularization. Titration of the doses may be required.</li> <li>○ All patients who are post-NSTEMI-ACS should be given sublingual or spray nitroglycerin with verbal and written instructions for its use.</li> <li>○ Before hospital discharge, patients with NSTEMI-ACS should be informed about symptoms of worsening myocardial ischemia and MI and should be given verbal and written instructions about how and when to seek emergency care for such symptoms.</li> <li>○ Before hospital discharge, patients who are post-NSTEMI-ACS and/or designated responsible caregivers should be provided with easily understood and culturally sensitive verbal and written instructions about medication type, purpose, dose, frequency, side effects, and duration of use.</li> <li>○ For patients who are post-NSTEMI-ACS and have initial angina lasting more than one minute, nitroglycerin (one dose sublingual or spray) is recommended if angina does not subside within three to five minutes; call 9-1-1 immediately to access emergency medical services.</li> <li>○ If the pattern or severity of angina changes, suggesting worsening myocardial ischemia (e.g., pain is more frequent or severe or is precipitated by less effort or occurs at rest), patients should contact their clinician without delay to assess the need for additional treatment or testing.</li> <li>○ Before discharge, patients should be educated about modification of cardiovascular risk factors.</li> </ul> </li> <li>• Late hospital and post-hospital oral antiplatelet therapy <ul style="list-style-type: none"> <li>○ Aspirin should be continued indefinitely. The dose should be 81 mg daily in patients treated with ticagrelor and 81 to 325 mg daily in all other patients.</li> <li>○ In addition to aspirin, a P2Y<sub>12</sub> inhibitor (either clopidogrel or ticagrelor) should be continued for up to 12 months in all patients with NSTEMI-ACS without contraindications who are treated with an ischemia-guided strategy.</li> <li>○ In patients receiving a stent (bare-metal stent or DES) during PCI for NSTEMI-ACS, P2Y<sub>12</sub> inhibitor therapy should be given for at least 12 months.</li> </ul> </li> <li>• Combined oral anticoagulant therapy and antiplatelet therapy in patients with NSTEMI-ACS <ul style="list-style-type: none"> <li>○ The duration of triple antithrombotic therapy with a vitamin K antagonist, aspirin, and a P2Y<sub>12</sub> receptor inhibitor in patients with NSTEMI-ACS should be minimized to the extent possible to limit the risk of bleeding.</li> <li>○ Proton pump inhibitors should be prescribed in patients with NSTEMI-ACS with a history of gastrointestinal bleeding who require triple antithrombotic therapy with a vitamin K antagonist, aspirin, and a P2Y<sub>12</sub> receptor inhibitor.</li> </ul> </li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Management of Acute Coronary Syndromes in Patients Presenting without Persistent ST-Segment</b></p>	<p><b>Pharmacological treatment of ischemia</b></p> <ul style="list-style-type: none"> <li>• Sublingual or intravenous nitrates and early initiation of <math>\beta</math>-blocker treatment is recommended in patients with ongoing ischemic symptoms and without contraindications.</li> <li>• Continuation of chronic <math>\beta</math>-blocker therapy is recommended unless the patient is in overt heart failure.</li> <li>• Sublingual or intravenous nitrates are recommended to relieve angina; intravenous treatment is recommended in patients with recurrent angina, uncontrolled hypertension, or signs of heart failure.</li> </ul>

Clinical Guideline	Recommendations
<p><b>Elevation (2020)<sup>24</sup></b></p>	<ul style="list-style-type: none"> <li>• In patients with suspected/confirmed vasospastic angina, calcium channel blockers, and nitrates should be considered and <math>\beta</math>-blockers avoided.</li> </ul> <p><u>Recommendations for platelet inhibition in non-ST-elevation acute coronary syndromes</u></p> <ul style="list-style-type: none"> <li>• Aspirin is recommended for all patients without contraindications at an initial oral loading dose of 150 to 300 mg (in aspirin-naïve patients) and a maintenance dose of 75 to 100 mg/day long-term regardless of treatment strategy.</li> <li>• A P2Y<sub>12</sub> inhibitor is recommended, in addition to aspirin, for 12 months unless there are contraindications such as excessive risks of bleeds.             <ul style="list-style-type: none"> <li>○ Ticagrelor (180 mg loading dose, 90 mg twice daily) is recommended, in the absence of contraindication, for all patients at moderate-to-high risk of ischemic events (e.g., elevated cardiac troponins), regardless of initial treatment strategy and including those pretreated with clopidogrel (which should be discontinued when ticagrelor is started).</li> <li>○ Prasugrel (60 mg loading dose, 10 mg daily dose) is recommended in patients who are proceeding to PCI if no contraindication. Prasugrel should be considered in preference to ticagrelor in NSTEMI-ACS patients who proceed to PCI.</li> <li>○ Clopidogrel (300 to 600 mg loading dose, 75 mg daily dose) is recommended for patients who cannot receive ticagrelor or prasugrel or who require oral anticoagulation.</li> </ul> </li> <li>• P2Y<sub>12</sub> inhibitor administration for a shorter duration of three to six months after DES implantation may be considered in patients deemed at high bleeding risk.</li> <li>• Pre-treatment with a P2Y<sub>12</sub> inhibitor may be considered in patients with NSTEMI-ACS who are not planned to undergo an early invasive strategy.</li> <li>• It is not recommended to administer routine pre-treatment with a P2Y<sub>12</sub> inhibitor in patients in whom coronary anatomy is not known.</li> <li>• It is not recommended to administer prasugrel in patients whom coronary anatomy is not known.</li> <li>• GPIIb/IIIa inhibitors during PCI should be considered for bailout situations or thrombotic complications.</li> <li>• Cangrelor may be considered in P2Y<sub>12</sub> inhibitor-naïve patients undergoing PCI.</li> <li>• It is not recommended to administer GPIIb/IIIa inhibitors in patients whom coronary anatomy is not known.</li> <li>• P2Y<sub>12</sub> inhibitor administration in addition to aspirin beyond one year may be considered after careful assessment of the ischemic and bleeding risks of the patient.</li> </ul> <p><u>Recommendations for anticoagulation in non-ST-elevation acute coronary syndromes</u></p> <ul style="list-style-type: none"> <li>• Parenteral anticoagulation is recommended at the time of diagnosis according to both ischemic and bleeding risks.</li> <li>• Fondaparinux is recommended as having the most favorable efficacy-safety profile regardless of the management strategy.</li> <li>• Bivalirudin is recommended as an alternative to UFH plus GPIIb/IIIa inhibitors during PCI.</li> <li>• UFH is recommended in patients undergoing PCI who did not receive any anticoagulant.</li> <li>• In patients on fondaparinux undergoing PCI, a single intravenous bolus of UFH is recommended during the procedure.</li> <li>• Enoxaparin or UFH are recommended when fondaparinux is not available.</li> <li>• Enoxaparin should be considered as an anticoagulant for PCI in patients pretreated for PCI with subcutaneous enoxaparin.</li> <li>• Additional activated clotting time-guided intravenous boluses of UFH during PCI may be considered following initial UFH treatment.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Discontinuation of anticoagulation should be considered after PCI, unless otherwise indicated.</li> <li>• Crossover between UFH and LMWH is not recommended.</li> <li>• In NSTEMI patients with no prior stroke/TIA and at high ischemic risk as well as low bleeding risk receiving aspirin and clopidogrel, low-dose rivaroxaban (2.5 mg twice daily for approximately one year) may be considered after discontinuation of parenteral anticoagulation.</li> </ul> <p><u>Recommendations for combining antiplatelet agents and anticoagulants in non-ST-elevation acute coronary syndrome patients requiring chronic oral anticoagulation</u></p> <ul style="list-style-type: none"> <li>• In patients with a firm indication for oral anticoagulation (e.g., atrial fibrillation with a CHADS<sub>2</sub>-VASc score <math>\geq 2</math>, recent VTE, mechanical valve prosthesis), oral anticoagulation is recommended in addition to antiplatelet therapy.</li> <li>• An early invasive coronary angiography (within 24 hours) should be considered in moderate- to high-risk patients, irrespective of oral anticoagulant exposure, to expedite treatment allocation (medical vs PCI vs CABG) and to determine optimal antithrombotic regimen.</li> <li>• Initial dual antiplatelet therapy with aspirin plus a P2Y<sub>12</sub> inhibitor in addition to oral anticoagulation before coronary angiography is not recommended.</li> <li>• During PCI, additional parenteral anticoagulation is recommended, irrespective of the timing of the last dose of all non-vitamin K antagonist oral anticoagulants (NOACs) and if INR is <math>&lt; 2.5</math> in VKA-treated patients.</li> <li>• Uninterrupted therapeutic anticoagulation with VKA or NOACs should be considered during the periprocedural phase.</li> <li>• Periprocedural DAPT administration consisting of aspirin and clopidogrel up to one week is recommended</li> <li>• Discontinuation of antiplatelet treatment in patients treated with an oral anticoagulant is recommended after 12 months</li> <li>• Following coronary stenting, dual (oral) antiplatelet therapy (DAPT) including new P2Y<sub>12</sub> inhibitors should be considered as an alternative to triple therapy for patients with non-ST-elevation acute coronary syndromes and atrial fibrillation with a CHADS<sub>2</sub>-VASc score of 1 (in males) or 2 (in females).</li> <li>• If at low bleeding risk (HAS-BLED <math>\leq 2</math>), triple therapy with oral anticoagulant, aspirin, and clopidogrel should be considered for six months, followed by oral anticoagulant and aspirin or clopidogrel continued up to 12 months.</li> <li>• If at high bleeding risk (HAS-BLED <math>\geq 3</math>), triple therapy with oral anticoagulant, aspirin, and clopidogrel should be considered for one month, followed by oral anticoagulant and aspirin or clopidogrel continued up to 12 months irrespective of the stent type.</li> <li>• Dual therapy with oral anticoagulant and clopidogrel may be considered as an alternative to triple antithrombotic therapy in selected patients (HAS-BLED <math>\geq 3</math> and low risk of stent thrombosis).</li> <li>• The use of ticagrelor or prasugrel as part of triple therapy is not recommended.</li> <li>• In medically managed patients, one antiplatelet agent in addition to oral anticoagulant should be considered for up to one year.</li> </ul> <p><u>Recommendations for post-interventional and maintenance treatment</u></p> <ul style="list-style-type: none"> <li>• In patients with NSTEMI-ACS with coronary stent implantation, DAPT with a P2Y<sub>12</sub> inhibitor on top of aspirin is recommended for 12 months unless there are contraindications such as excessive risk of bleeding.</li> <li>• Adding a second anti-thrombotic agent to aspirin for extended long-term secondary prevention should be considered in patients with a moderate to high risk of ischemic events and without increased risk of major bleeding.</li> <li>• After stent implantation with high risk of bleeding, discontinuation of P2Y<sub>12</sub> inhibitor therapy after three months should be considered</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• After stent implantation in patients undergoing DAPT, stopping aspirin after three to six months should be considered, depending on balance between ischemic and bleeding risk.</li> <li>• De-escalation of P2Y<sub>12</sub> inhibitor treatment may be considered as an alternative DAPT strategy, especially for ACS patients deemed unsuitable for potent platelet inhibition.</li> </ul>
<p>American College of Cardiology/American Heart Association: <b>Guideline for the Management of ST-Elevation Myocardial Infarction (2013)</b><sup>25</sup></p>	<p><u>Routine medical therapies: <math>\beta</math>-blockers</u></p> <ul style="list-style-type: none"> <li>• Oral <math>\beta</math>-blockers should be initiated within the first 24 hours in patients with an ST-segment elevation myocardial infarction (STEMI) who do not have any of the following: 1) signs of heart failure, 2) evidence of a low-output state, 3) increased risk of cardiogenic shock, 4) other contraindications to use of oral <math>\beta</math>-blockers (e.g., PR interval &gt;24 seconds, second or third degree heart block, active asthma, reactive airway disease).</li> <li>• <math>\beta</math>-blockers should be continued during and after hospitalization for all patients with STEMI and with no contraindications to their use.</li> <li>• Patients with initial contraindications to the use of <math>\beta</math>-blockers in the first 24 hours after STEMI should be re-evaluated to determine their subsequent eligibility.</li> <li>• It is reasonable to administer intravenous <math>\beta</math>-blockers at the time of presentation to patients with STEMI and no contraindications to their use who are hypertensive or have ongoing ischemia.</li> </ul> <p><u>Routine medical therapies: renin-angiotensin-aldosterone system inhibitors</u></p> <ul style="list-style-type: none"> <li>• An ACE inhibitor should be administered within the first 24 hours to all patients with ST-segment elevation myocardial infarction with anterior location, heart failure, or ejection fraction <math>\leq 40\%</math>, unless contraindicated.</li> <li>• An ARB should be given to patients who have indications for but are intolerant of ACE inhibitors.</li> <li>• ACE inhibitors are reasonable for all patients with no contraindications to their use.</li> <li>• An aldosterone antagonist should be given to patients with STEMI and no contraindications who are already receiving an ACE inhibitor and <math>\beta</math>-blocker and who have an EF <math>\leq 40\%</math> and either symptomatic heart failure or diabetes.</li> </ul> <p><u>Routine medical therapies: Lipid management</u></p> <ul style="list-style-type: none"> <li>• High-intensity statin therapy should be initiated or continued in all patients with STEMI and no contraindications to its use.</li> <li>• It is reasonable to obtain a fasting lipid profile in patients with STEMI, preferably within 24 hours of presentation.</li> </ul>
<p>European Society of Cardiology: <b>Management of Acute Myocardial Infarction in Patients Presenting with ST-segment Elevation (2017)</b><sup>26</sup></p>	<p><u>Routine therapies in the acute, subacute and long term phase of ST-elevation myocardial infarction (STEMI)</u></p> <ul style="list-style-type: none"> <li>• Antiplatelet therapy with low dose aspirin (75 to 100 mg) is indicated indefinitely after STEMI.</li> <li>• Dual antiplatelet therapy with a combination of aspirin and prasugrel or aspirin and ticagrelor is recommended for 12 months after percutaneous coronary intervention (PCI), unless there are contraindications such as excessive risk of bleeding.</li> <li>• A proton pump inhibitor (PPI) in combination with dual antiplatelet therapy is recommended in patients at high risk of gastrointestinal bleeding.</li> <li>• In patients with an indication for oral anticoagulation, oral anticoagulants are indicated in addition to antiplatelet therapy.</li> <li>• In patients who are at high risk of severe bleeding complications, discontinuation of P2Y<sub>12</sub> inhibitor therapy after six months should be considered.</li> <li>• In STEMI patients with stent implantation and an indication for oral anticoagulation, triple therapy (oral anticoagulant, aspirin, and clopidogrel) should be considered for one to six months (according a balance between the</li> </ul>

Clinical Guideline	Recommendations
	<p>estimated risk of recurrent coronary events and bleeding).</p> <ul style="list-style-type: none"> <li>• In patients with left ventricular thrombus, anticoagulation should be instituted for a minimum of six months, guided by repeated imaging.</li> <li>• In selected patients who receive aspirin and clopidogrel, low-dose rivaroxaban (2.5 mg twice daily) may be considered if the patient is at low bleeding risk.</li> <li>• Dual antiplatelet therapy should be used up to one year in patients with STEMI who did not receive a stent unless there are contraindications such as excessive risk of bleeding.</li> <li>• In high ischemic-risk patients (age <math>\geq 50</math> years, and at least one of the following risk factors: age <math>\geq 65</math> years, diabetes mellitus on medication, prior spontaneous MAI, multivessel CAD, or chronic renal dysfunction with eGFR <math>&lt; 60</math> mL/min) who have tolerated dual antiplatelet therapy without a bleeding complication, treatment with dual antiplatelet therapy in the form of ticagrelor 60 mg twice a day on top of aspirin for longer than 12 months may be considered for up to three years.</li> <li>• The use of ticagrelor or prasugrel is not recommended as part of triple antithrombotic therapy with aspirin and oral anticoagulation.</li> <li>• Oral treatment with <math>\beta</math>-blockers should be considered during hospital stay and continued thereafter in all patients without contraindications.</li> <li>• Oral treatment with <math>\beta</math>-blockers is indicated in patients with heart failure or left ventricular dysfunction, LVEF <math>\leq 40\%</math> unless contraindicated.</li> <li>• Intravenous <math>\beta</math>-blockers must be avoided in patients with hypotension or acute heart failure or AV block or severe bradycardia.</li> <li>• Intravenous <math>\beta</math>-blockers should be considered at the time of presentation in patients undergoing primary PCI without contraindications, with high blood pressure, tachycardia, and no signs of heart failure.</li> <li>• A fasting lipid profile must be obtained in all STEMI patients, as soon as possible after presentation.</li> <li>• It is recommended to initiate or continue high dose statins early after admission in all STEMI patients without contraindication or history of intolerance, regardless of initial cholesterol values and maintain it long-term.</li> <li>• An LDL-C goal of <math>&lt; 1.8</math> mmol/L (70 mg/dL) or a reduction of at least 50% if the baseline LDL-C is between 1.8 to 3.5 mmol/L (70 to 135 mg/dL) is recommended.</li> <li>• In patients with LDL-C <math>&gt; 1.8</math> mmol/L (<math>&gt; 70</math> mg/dL) despite a maximally tolerated statin dose who remain at high risk, further therapy to reduce LDL-C should be considered.</li> <li>• ACE inhibitors are indicated starting within the first 24 hours of STEMI in patients with evidence of heart failure, LV systolic dysfunction, diabetes or an anterior infarct.</li> <li>• An ARB, preferably valsartan, is an alternative to ACE inhibitors in patients with heart failure or LV systolic dysfunction, particularly those who are intolerant to ACE inhibitors.</li> <li>• ACE inhibitors should be considered in all patients in the absence of contraindications.</li> <li>• Aldosterone antagonists, e.g. eplerenone, are indicated in patients with an ejection fraction <math>\leq 40\%</math> and heart failure or diabetes, provided no renal failure or hyperkalemia.</li> </ul>
<p>American College of Cardiology/ American Heart Association: <b>Guideline on the Primary Prevention of Cardiovascular Disease</b></p>	<p><u>Top 10 messages for the primary prevention of cardiovascular disease</u></p> <ul style="list-style-type: none"> <li>• The most important way to prevent atherosclerotic vascular disease, heart failure, and atrial fibrillation is to promote a healthy lifestyle throughout life.</li> <li>• A team-based care approach is an effective strategy for the prevention of cardiovascular disease. Clinicians should evaluate the social determinants of health that affect individuals to inform treatment decisions.</li> <li>• Adults who are 40 to 75 years of age and are being evaluated for cardiovascular</li> </ul>

Clinical Guideline	Recommendations
(2019) <sup>27</sup>	<p>disease prevention should undergo 10-year atherosclerotic cardiovascular disease (ASCVD) risk estimation and have a clinician–patient risk discussion before starting on pharmacological therapy, such as antihypertensive therapy, a statin, or aspirin. In addition, assessing for other risk-enhancing factors can help guide decisions about preventive interventions in select individuals, as can coronary artery calcium scanning.</p> <ul style="list-style-type: none"> <li>• All adults should consume a healthy diet that emphasizes the intake of vegetables, fruits, nuts, whole grains, lean vegetable or animal protein, and fish and minimizes the intake of trans fats, processed meats, refined carbohydrates, and sweetened beverages. For adults with overweight and obesity, counseling and caloric restriction are recommended for achieving and maintaining weight loss.</li> <li>• Adults should engage in at least 150 minutes per week of accumulated moderate-intensity physical activity or 75 minutes per week of vigorous-intensity physical activity.</li> <li>• For adults with type 2 diabetes mellitus, lifestyle changes, such as improving dietary habits and achieving exercise recommendations, are crucial. If medication is indicated, metformin is first-line therapy, followed by consideration of a sodium-glucose cotransporter 2 inhibitor or a glucagon-like peptide-1 receptor agonist.</li> <li>• All adults should be assessed at every healthcare visit for tobacco use, and those who use tobacco should be assisted and strongly advised to quit.</li> <li>• Aspirin should be used infrequently in the routine primary prevention of ASCVD because of lack of net benefit.</li> <li>• Statin therapy is first-line treatment for primary prevention of ASCVD in patients with elevated low-density lipoprotein cholesterol levels (<math>\geq 190</math> mg/dL), those with diabetes mellitus, who are 40 to 75 years of age, and those determined to be at sufficient ASCVD risk after a clinician–patient risk discussion.</li> <li>• Nonpharmacological interventions are recommended for all adults with elevated blood pressure or hypertension. For those requiring pharmacological therapy, the target blood pressure should generally be <math>&lt; 130/80</math> mm Hg.</li> </ul> <p><u>Adults with Type 2 Diabetes Mellitus</u></p> <ul style="list-style-type: none"> <li>• For all adults with T2DM, a tailored nutrition plan focusing on a heart-healthy dietary pattern is recommended to improve glycemic control, achieve weight loss if needed, and improve other ASCVD risk factors.</li> <li>• Adults with T2DM should perform at least 150 minutes per week of moderate-intensity physical activity or 75 minutes of vigorous-intensity physical activity to improve glycemic control, achieve weight loss if needed, and improve other ASCVD risk factors.</li> <li>• For adults with T2DM, it is reasonable to initiate metformin as first-line therapy along with lifestyle therapies at the time of diagnosis to improve glycemic control and reduce ASCVD risk.</li> <li>• For adults with T2DM and additional ASCVD risk factors who require glucose-lowering therapy despite initial lifestyle modifications and metformin, it may be reasonable to initiate a sodium-glucose cotransporter 2 (SGLT-2) inhibitor or a glucagon-like peptide-1 receptor (GLP-1R) agonist to improve glycemic control and reduce CVD risk.</li> </ul> <p><u>Adults with high blood cholesterol</u></p> <ul style="list-style-type: none"> <li>• In adults at intermediate risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk), statin therapy reduces risk of ASCVD, and in the context of a risk discussion, if a decision is made for statin therapy, a moderate-intensity statin should be recommended.</li> <li>• In intermediate risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk) patients, LDL-C</li> </ul>

Clinical Guideline	Recommendations
	<p>levels should be reduced by 30% or more, and for optimal ASCVD risk reduction, especially in patients at high risk (<math>\geq 20\%</math> 10-year ASCVD risk), levels should be reduced by 50% or more.</p> <ul style="list-style-type: none"> <li>• In adults 40 to 75 years of age with diabetes, regardless of estimated 10-year ASCVD risk, moderate-intensity statin therapy is indicated.</li> <li>• In patients 20 to 75 years of age with an LDL-C level of 190 mg/dL (<math>\geq 4.9</math> mmol/L) or higher, maximally tolerated statin therapy is recommended.</li> <li>• In adults with diabetes mellitus who have multiple ASCVD risk factors, it is reasonable to prescribe high-intensity statin therapy with the aim to reduce LDL-C levels by 50% or more.</li> <li>• In intermediate-risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk) adults, risk-enhancing factors favor initiation or intensification of statin therapy.</li> <li>• In intermediate-risk (<math>\geq 7.5\%</math> to <math>&lt; 20\%</math> 10-year ASCVD risk) adults or selected borderline-risk (5% to <math>&lt; 7.5\%</math> 10-year ASCVD risk) adults in whom a coronary artery calcium score is measured for the purpose of making a treatment decision, AND <ul style="list-style-type: none"> <li>○ If the coronary artery calcium score is zero, it is reasonable to withhold statin therapy and reassess in five to 10 years, as long as higher-risk conditions are absent (e.g., diabetes, family history of premature CHD, cigarette smoking);</li> <li>○ If coronary artery calcium score is one to 99, it is reasonable to initiate statin therapy for patients <math>\geq 55</math> years of age;</li> <li>○ If coronary artery calcium score is 100 or higher or in the 75th percentile or higher, it is reasonable to initiate statin therapy.</li> </ul> </li> <li>• In patients at borderline risk (5% to <math>&lt; 7.5\%</math> 10-year ASCVD risk), in risk discussion, the presence of risk-enhancing factors may justify initiation of moderate-intensity statin therapy.</li> </ul> <p><u>Adults with high blood pressure or hypertension</u></p> <ul style="list-style-type: none"> <li>• In adults with elevated blood pressure (BP) or hypertension, including those requiring antihypertensive medications nonpharmacological interventions are recommended to reduce BP. These include: <ul style="list-style-type: none"> <li>○ weight loss;</li> <li>○ a heart-healthy dietary pattern;</li> <li>○ sodium reduction;</li> <li>○ dietary potassium supplementation;</li> <li>○ increased physical activity with a structured exercise program; and</li> <li>○ limited alcohol.</li> </ul> </li> <li>• In adults with an estimated 10-year ASCVD risk (ACC/AHA pooled cohort equations to estimate 10-year risk of ASCVD) of 10% or higher and an average systolic BP (SBP) of 130 mm Hg or higher or an average diastolic BP (DBP) of 80 mm Hg or higher, use of BP-lowering medications is recommended for primary prevention of CVD.</li> <li>• In adults with confirmed hypertension and a 10-year ASCVD event risk of 10% or higher, a BP target of less than 130/80 mm Hg is recommended.</li> <li>• In adults with hypertension and chronic kidney disease, treatment to a BP goal of less than 130/80 mm Hg is recommended.</li> <li>• In adults with T2DM and hypertension, antihypertensive drug treatment should be initiated at a BP of 130/80 mm Hg or higher, with a treatment goal of less than 130/80 mm Hg.</li> <li>• In adults with an estimated 10-year ASCVD risk <math>&lt; 10\%</math> and an SBP of 140 mm Hg or higher or a DBP of 90 mm Hg or higher, initiation and use of BP-lowering medication are recommended.</li> <li>• In adults with confirmed hypertension without additional markers of increased ASCVD risk, a BP target of less than 130/80 mm Hg may be reasonable.</li> </ul>

Clinical Guideline	Recommendations
	<p><u>Recommendations for treatment of tobacco use</u></p> <ul style="list-style-type: none"> <li>• All adults should be assessed at every healthcare visit for tobacco use and their tobacco use status recorded as a vital sign to facilitate tobacco cessation.</li> <li>• To achieve tobacco abstinence, all adults who use tobacco should be firmly advised to quit.</li> <li>• In adults who use tobacco, a combination of behavioral interventions plus pharmacotherapy is recommended to maximize quit rates.</li> <li>• In adults who use tobacco, tobacco abstinence is recommended to reduce ASCVD risk.</li> <li>• To facilitate tobacco cessation, it is reasonable to dedicate trained staff to tobacco treatment in every healthcare system.</li> <li>• All adults and adolescents should avoid secondhand smoke exposure to reduce ASCVD risk.</li> </ul> <p><u>Recommendations for aspirin use</u></p> <ul style="list-style-type: none"> <li>• Low-dose aspirin (75 to 100 mg orally daily) might be considered for the primary prevention of ASCVD among select adults 40 to 70 years of age who are at higher ASCVD risk but not at increased bleeding risk.</li> <li>• Low-dose aspirin (75 to 100 mg orally daily) should not be administered on a routine basis for the primary prevention of ASCVD among adults &gt;70 years of age.</li> <li>• Low-dose aspirin (75 to 100 mg orally daily) should not be administered for the primary prevention of ASCVD among adults of any age who are at increased risk of bleeding.</li> </ul>
<p>American Heart Association/American College of Cardiology/Heart Failure Society of America: <b>2022 AHA/ACC/HFSA Guideline for the Management of Heart Failure (2022)</b><sup>28</sup></p>	<p><u>Treatment of Stage A heart failure (HF)</u></p> <ul style="list-style-type: none"> <li>• Hypertension should be controlled in accordance with guideline-directed medication therapy for hypertension to prevent symptomatic HF. (LoE: A)</li> <li>• In patients with type 2 diabetes and either established CVD or at high cardiovascular risk, SGLT-2 inhibitors should be used to prevent hospitalizations for HF. (LoE: A)</li> <li>• In the general population, healthy lifestyle habits such as regular physical activity, maintaining normal weight, healthy dietary patterns, and avoiding smoking are helpful to reduce future risk of HF. (LoE: B)</li> <li>• Patients at risk of developing HF, natriuretic peptide biomarker-based screening followed by team-based care, including a cardiovascular specialist optimizing therapy, can be useful to prevent the development of LV dysfunction (systolic or diastolic) or new-onset HF. (LoE: B)</li> </ul> <p><u>Treatment of Stage B heart failure</u></p> <ul style="list-style-type: none"> <li>• In patients with LVEF≤40%, ACE inhibitors should be used to prevent HF and reduce mortality. (LoE: A)</li> <li>• In patients with a recent or remote history of MI or ACS, statins should be used to prevent symptomatic HF and adverse cardiovascular events. (LoE: A)</li> <li>• In patients with a recent MI and LVEF≤40% who are intolerant to ACE inhibitors, ARB should be used to prevent symptomatic HF and reduce mortality. (LoE: B)</li> <li>• In patients with a recent or remote history of MI or ACS and LVEF≤40%, evidence-based beta blockers should be used to reduce mortality. (LoE: B)</li> <li>• In patients who are at least 40 days post-MI with LVEF ≤30% and NYHA class I symptoms while receiving guideline-directed medication therapy and have reasonable expectation of meaningful survival for greater than one year, an implantable cardioverter-defibrillator is recommended for primary prevention of sudden cardiac death to reduce total mortality. (LoE: B)</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In patients with LVEF <math>\leq</math>40%, beta blockers should be used to prevent symptomatic HF. (LoE: C)</li> <li>• In patients with LVEF <math>\leq</math>50%, thiazolidinediones should not be used because they increase the risk of HF, including hospitalizations. (LoE: B)</li> <li>• In patients with LVEF <math>\leq</math>50%, nondihydropyridine calcium channel blockers with negative inotropic effects may be harmful. (LoE: C)</li> </ul> <p><b>Treatment for Stage C Heart Failure with Reduced Ejection Fraction (HFrEF)</b></p> <ul style="list-style-type: none"> <li>• For patients with stage C HF, avoiding excessive sodium intake is reasonable to reduce congestive symptoms. (LoE: C)</li> <li>• In patients with HF who have fluid retention, diuretics are recommended to relieve congestion, improve symptoms, and prevent worsening HF. (LoE: B)</li> <li>• For patients with HF and congestive symptoms, addition of a thiazide (e.g., metolazone) to treatment with a loop diuretic should be reserved for patients who do not respond to moderate or high dose loop diuretics to minimize electrolyte abnormalities. (LoE: B)</li> <li>• In patients with HFrEF and NYHA class II to III symptoms, the use of an ARNI is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, the use of an ACE inhibitor is beneficial to reduce morbidity and mortality when the use of an ARNI is not feasible. (LoE: A)</li> <li>• In patients with previous or current symptoms of chronic HFrEF, who are intolerant to an ACE inhibitor because of cough or angioedema, and when the use of an ARNI is not feasible, the use of an ARB is recommended to reduce morbidity and mortality. (LoE: A)</li> <li>• In patients with chronic symptomatic HFrEF NYHA class II or III who tolerate an ACE inhibitor or ARB, replacement by an ARNI is recommended to further reduce morbidity and mortality. (LoE: B)</li> <li>• ARNIs should not be administered concomitantly with ACE inhibitors or within 36 hours of the last dose of an ACE inhibitor. (LoE: B)</li> <li>• ARNI or ACE inhibitors should not be administered in patients with a history of angioedema. (LoE: C)</li> <li>• In patients with HFrEF, with current or previous symptoms, use of one of the three <math>\beta</math>-blockers proven to reduce mortality (e.g., bisoprolol, carvedilol, sustained-release metoprolol succinate) is recommended to reduce mortality and hospitalizations. (LoE: A)</li> <li>• In patients with HFrEF and NYHA class II to IV symptoms, a mineralocorticoid receptor antagonist (spironolactone or eplerenone) is recommended to reduce morbidity and mortality, if eGFR is <math>&gt;</math>30 mL/min/1.73 m<sup>2</sup> and serum potassium is <math>&lt;</math>5.0 mEq/L. Careful monitoring of potassium, renal function, and diuretic dosing should be performed at initiation and closely followed thereafter to minimize risk of hyperkalemia and renal insufficiency. (LoE: A)</li> <li>• In patients taking a mineralocorticoid receptor antagonist whose serum potassium cannot be maintained at <math>&lt;</math>5.5 mEq/L, mineralocorticoid receptor antagonist should be discontinued to avoid life threatening hyperkalemia. (LoE: B)</li> <li>• In patients with symptomatic chronic HFrEF, SGLT-2 an inhibitor is recommended to reduce hospitalization for HF and cardiovascular mortality, irrespective of the presence of type 2 diabetes. (LoE: A)</li> <li>• The combination of hydralazine and isosorbide dinitrate is recommended to improve symptoms and reduce morbidity and mortality for patients self-identified as African Americans with NYHA class III to IV HFrEF receiving optimal therapy. (LoE: A)</li> <li>• In patients with current or previous symptomatic HFrEF who cannot be given first-line agents, such as an ARNI, ACE inhibitor or ARB because of drug intolerance or renal insufficiency, a combination of hydralazine and isosorbide</li> </ul>

Clinical Guideline	Recommendations
	<p>dinitrate might be considered to reduce morbidity and mortality. (LoE: C)</p> <ul style="list-style-type: none"> <li>• In patients with HF class II to IV symptoms, omega-3 polyunsaturated fatty acid supplementation may be reasonable to use as adjunctive therapy to reduce mortality and cardiovascular hospitalizations. (LoE: B)</li> <li>• In patients with chronic HFrEF without specific indication (e.g., venous thromboembolism, atrial fibrillation, a previous thromboembolic event, or a cardioembolic source, anticoagulation is not recommended. (LoE: B)</li> <li>• Dihydropyridine and non-dihydropyridine calcium channel blockers are not recommended for patients with HFrEF. (LoE: A)</li> <li>• In patients with HFrEF, vitamins, nutritional supplements, and hormonal therapy are not recommended other than to correct specific deficiencies. (LoE: B)</li> <li>• In patients with HFrEF, class IC antiarrhythmic medication and dronedarone may increase risk of mortality. (LoE: A)</li> <li>• In patients with HFrEF, thiazolidinediones increase the risk of worsening HF symptoms and hospitalizations. (LoE: A)</li> <li>• In patients with type 2 diabetes and high cardiovascular risk, the DPP-4 inhibitors, saxagliptin and alogliptin, increase the risk of HF hospitalization and should be avoided in patients with HF. (LoE: B)</li> <li>• In patients with HFrEF, nonsteroidal anti-inflammatory drugs worsen HF symptoms and should be avoided or withdrawn whenever possible. (LoE: B)</li> <li>• For patients with symptomatic (NYHA class II to III) stable chronic HFrEF (LVEF <math>\leq</math>35%) who are receiving guideline-directed medical therapy, including a maximally tolerated dose of a beta blocker, and who are in sinus rhythm with a heart rate of <math>\geq</math>70 beats per minute at rest, ivabradine can be beneficial to reduce HF hospitalizations and cardiovascular death. (LoE: B)</li> <li>• In patients with symptomatic HFrEF despite guideline-directed medical therapy or who are unable to tolerate guideline-directed medical therapy, digoxin might be considered to decrease hospitalizations for HF. (LoE: B)</li> <li>• In select high-risk patients with HFrEF and recent worsening of HF already on guideline-directed medical therapy, an oral soluble guanylate cyclase stimulator (vericiguat) may be considered to reduce HF hospitalization and cardiovascular death. (LoE: B)</li> </ul> <p><u>Pharmacological treatment for Stage C HF with mildly reduced EF and improved EF</u></p> <ul style="list-style-type: none"> <li>• In patients with HF with mildly reduced EF, SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• Among patients with current or previous symptomatic HF with mildly reduced EF (LVEF, 41 to 49%), use of evidence-based beta blockers for HFrEF, ARNI, ACE inhibitor or ARB, and mineralocorticoid receptor antagonists may be considered to reduce the risk of HF hospitalization and cardiovascular mortality, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> <li>• In patients with HF with improved EF after treatment, guideline-directed medical therapy should be continued to prevent relapse of HF and LV dysfunction, even in patients who may become asymptomatic. (LoE: B)</li> </ul> <p><u>Pharmacological treatment for Stage C HF with preserved EF (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• Patients with hypertension and HFpEF should have medication titrated to attain blood pressure targets in accordance with published clinical practice guidelines to prevent morbidity. (LoE: C)</li> <li>• SGLT-2 inhibitors can be beneficial in decreasing HF hospitalizations and cardiovascular mortality. (LoE: B)</li> <li>• In patients with HFpEF, the use of a mineralocorticoid receptor antagonist, ARB, or ARNI may be considered to decrease hospitalizations, particularly among patients with LVEF on the lower end of this spectrum. (LoE: B)</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Routine use of nitrates or phosphodiesterase-5 inhibitors to increase activity or quality of life in patients with HFpEF is ineffective. (LoE: B)</li> </ul> <p><u>Treatment of Stage D (advanced/refractory) HF</u></p> <ul style="list-style-type: none"> <li>• For patients with advanced HF and hyponatremia, the benefit of fluid restriction to reduce congestive symptoms is uncertain. (LoE: C)</li> <li>• Continuous intravenous inotropic support is reasonable as “bridge therapy” in patients with HF (Stage D) refractory to guideline-directed medical therapy and device therapy who are eligible for and awaiting mechanical circulatory support or cardiac transplantation. (LoE: B)</li> <li>• In select patients with HF Stage D, despite optimal guideline-directed medical therapy and device therapy who are ineligible for either mechanical circulatory support or cardiac transplantation, continuous intravenous inotropic support may be considered as palliative therapy for symptom control and improvement in functional status. (LoE: B)</li> <li>• Long-term use of either continuous or intermittent, intravenous inotropic agents, for reasons other than palliative care or as a bridge to advanced therapies, is potentially harmful. (LoE: B)</li> </ul>
<p>European Society of Cardiology: <b>Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure (2021)</b><sup>29</sup></p>	<p><u>Pharmacological treatments indicated in patients with (NYHA Class II-IV) heart failure with reduced ejection fraction</u></p> <ul style="list-style-type: none"> <li>• An ACE inhibitor is recommended, in addition to a <math>\beta</math>-blocker, for symptomatic patients with HFrEF to reduce the risk of HF hospitalization and death.</li> <li>• A mineralocorticoid receptor antagonist (MRA) is recommended for patients with HFrEF, who remain symptomatic despite treatment with an ACE inhibitor and a <math>\beta</math>-blocker, to reduce the risk of HF hospitalization and death.</li> <li>• Dapagliflozin or empagliflozin are recommended for patients with HFrEF to reduce the risk of HF hospitalization and death. Dapagliflozin or empagliflozin are recommended, in addition to optimal medical therapy with an ACE-I/ARNI, a <math>\beta</math>-blocker and an MRA, for patients with HFrEF regardless of diabetes status.</li> <li>• Sacubitril-valsartan is recommended as a replacement for an ACE inhibitor to further reduce the risk of HF hospitalization and death in ambulatory patients with HFrEF who remain symptomatic despite optimal treatment with an ACE inhibitor, a <math>\beta</math>-blocker, and a mineralocorticoid receptor antagonist.</li> <li>• Diuretics are recommended in order to improve symptoms and exercise capacity in patients with signs and/or symptoms of congestion.</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization or cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm despite treatment with an evidence-based dose of <math>\beta</math>-blocker (or maximum tolerated dose below that), ACE inhibitor (or ARB), and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• Ivabradine should be considered to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients with LVEF <math>\leq 35\%</math>, in sinus rhythm and a resting heart rate <math>\geq 70</math> bpm who are unable to tolerate or have contraindications for a <math>\beta</math>-blocker. Patients should also receive an ACE inhibitor (or ARB) and a mineralocorticoid receptor antagonist (or ARB).</li> <li>• An ARB is recommended to reduce the risk of HF hospitalization and cardiovascular death in symptomatic patients unable to tolerate an ACE inhibitor (patients should also receive a <math>\beta</math>-blocker and mineralocorticoid receptor antagonist).</li> <li>• An ARB may be considered to reduce the risk of HF hospitalization and death in patients who are symptomatic despite treatment with a <math>\beta</math>-blocker who are unable to tolerate a mineralocorticoid receptor antagonist.</li> <li>• Vericiguat may be considered in patients in NYHA class II-IV who have had worsening HF despite treatment with an ACE-I (or ARNI), a <math>\beta</math>-blocker and an MRA to reduce the risk of CV mortality or HF hospitalization.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Hydralazine and isosorbide dinitrate should be considered in self-identified black patients with LVEF <math>\leq 35\%</math> or with an LVEF <math>&lt; 45\%</math> combined with a dilated LV in NYHA Class III–IV despite treatment with an ACE-I a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist to reduce the risk of HF hospitalization and death.</li> <li>• Hydralazine and isosorbide dinitrate may be considered in symptomatic patients with HFrEF who can tolerate neither an ACE inhibitor nor an ARB (or they are contraindicated) to reduce the risk of death.</li> <li>• Digoxin is a treatment with less-certain benefits and may be considered in symptomatic patients in sinus rhythm despite treatment with an ACE inhibitor (or ARB), a <math>\beta</math>-blocker and a mineralocorticoid receptor antagonist, to reduce the risk of hospitalization (both all-cause and HF-hospitalizations).</li> </ul> <p><u>Recommendations for treatment of patients with (NYHA class II-IV) heart failure with mildly reduced ejection fraction (HFmrEF)</u></p> <ul style="list-style-type: none"> <li>• Diuretics are recommended in patients with congestion and HFmrEF in order to alleviate symptoms and signs.</li> <li>• An ACE inhibitor may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An ARB may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• A <math>\beta</math>-blocker may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• An MRA may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> <li>• Sacubitril/valsartan may be considered for patients with HFmrEF to reduce the risk of HF hospitalization and death.</li> </ul> <p><u>Recommendations for treatment of patients with heart failure with preserved ejection fraction (HFpEF)</u></p> <ul style="list-style-type: none"> <li>• It is recommended to screen patients with HFpEF for both cardiovascular and noncardiovascular comorbidities, which, if present, should be treated provided safe and effective interventions exist to improve symptoms, well-being and/or prognosis.</li> <li>• Diuretics are recommended in congested patients with HFpEF in order to alleviate symptoms and signs.</li> </ul> <p><u>Recommendations for the primary prevention of heart failure in patients with risk factors for its development</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension is recommended to prevent or delay the onset of HF and prolong life.</li> <li>• Treatment with statins is recommended in patients at high risk of CV disease or with CV disease in order to prevent or delay the onset of HF, and to prevent HF hospitalizations.</li> <li>• SGLT2 inhibitors (canagliflozin, dapagliflozin, empagliflozin, ertugliflozin, sotagliflozin) are recommended in patients with diabetes at high risk of CV disease or with CV disease in order to prevent HF hospitalizations.</li> <li>• Counselling against sedentary habit, obesity, cigarette smoking, and alcohol abuse is recommended to prevent or delay the onset of HF.</li> </ul> <p><u>Recommendations for the initial management of patients with acute heart failure – pharmacotherapy</u></p> <ul style="list-style-type: none"> <li>• Intravenous loop diuretics are recommended for all patients with acute HF admitted with signs/symptoms of fluid overload to improve symptoms. It is recommended to regularly monitor symptoms, urine output, renal function and</li> </ul>

Clinical Guideline	Recommendations
	<p>electrolytes during use of intravenous diuretics.</p> <ul style="list-style-type: none"> <li>• Combination of a loop diuretic with thiazide type diuretic should be considered in patients with resistant oedema who do not respond to an increase in loop diuretic doses.</li> <li>• In patients with acute HF and SBP &gt;110 mmHg, intravenous vasodilators may be considered as initial therapy to improve symptoms and reduce congestion.</li> <li>• Inotropic agents may be considered in patients with SBP &lt;90 mmHg and evidence of hypoperfusion who do not respond to standard treatment, including fluid challenge, to improve peripheral perfusion and maintain end-organ function.</li> <li>• Inotropic agents are not recommended routinely, due to safety concerns, unless the patient has symptomatic hypotension and evidence of hypoperfusion.</li> <li>• A vasopressor, preferably norepinephrine, may be considered in patients with cardiogenic shock to increase blood pressure and vital organ perfusion.</li> <li>• Thromboembolism prophylaxis (e.g., with LMWH) is recommended in patients not already anticoagulated and with no contraindication to anticoagulation, to reduce the risk of deep venous thrombosis and pulmonary embolism.</li> <li>• Routine use of opiates is not recommended, unless in selected patients with severe/intractable pain or anxiety.</li> </ul>
<p>Eighth Joint National Committee (JNC 8): <b>2014 Evidence-based Guideline for the Management of High Blood Pressure in Adults (2014)</b><sup>30</sup></p>	<ul style="list-style-type: none"> <li>• Pharmacologic treatment should be initiated in patients ≥60 years of age to lower blood pressure at systolic blood pressure ≥150 mm Hg or diastolic blood pressure ≥90 mm Hg and to a goal systolic blood pressure &lt;150 mm Hg and goal diastolic blood pressure &lt;90 mm Hg. Adjustment of treatment is not necessary if treatment results in lower blood pressure and treatment is well tolerated and without adverse effects on health or quality of life.</li> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at diastolic blood pressure ≥90 mm Hg to a goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• In patients &lt;60 years of age, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥150 mm Hg to a goal diastolic blood pressure &lt;140 mm Hg.</li> <li>• For patients ≥18 years of age with chronic kidney disease or diabetes, pharmacologic treatment should be initiated to lower blood pressure at systolic blood pressure ≥140 mm Hg or diastolic blood pressure ≥90 mm Hg and to a goal systolic blood pressure &lt;140 mm Hg and goal diastolic blood pressure &lt;90 mm Hg.</li> <li>• Initial antihypertensive treatment for the general nonblack population, including those with diabetes, should include thiazide-type diuretic, calcium channel blocker (CCB), ACE inhibitor, or ARB.</li> <li>• Initial antihypertensive treatment for the general black population, including those with diabetes, should include thiazide-type diuretic or CCB.</li> <li>• For patients ≥18 years of age with chronic kidney disease regardless of race or diabetes status, initial (or add-on) treatment should include an ACE inhibitor or ARB to improve kidney outcomes.</li> <li>• The main goal of antihypertensive treatment is to attain and maintain goal blood pressure.</li> <li>• If goal blood pressure is not attained within a month of treatment, the dose of the initial drug should be increased or second drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• If goal is not achieved with two drugs, a third drug from the thiazide-type diuretic, CCB, ACE inhibitor, or ARB classes should be added.</li> <li>• An ACE inhibitor and ARB should not be used together.</li> <li>• Antihypertensive classes can be used if the patient is unable to achieve goal blood pressure with three agents or had a contraindication to a preferred class.</li> <li>• If blood pressure is not able to be achieved or in complicated patients, referral to a hypertension specialist may be indicated.</li> </ul>

Clinical Guideline	Recommendations
<p>International Society of Hypertension: <b>Global Hypertension Practice Guidelines (2020)</b><sup>31</sup></p>	<p><b>Lifestyle modifications</b></p> <ul style="list-style-type: none"> <li>• Lifestyle modification is the first line of antihypertensive treatment.</li> <li>• Salt reduction: Reduce salt added when preparing foods, and at the table. Avoid or limit consumption of high salt foods such as soy sauce, fast foods and processed food including breads and cereals high in salt.</li> <li>• Healthy diet: Eating a diet that is rich in whole grains, fruits, vegetables, polyunsaturated fats and dairy products and reducing food high in sugar, saturated fat and trans fats, such as the DASH diet.</li> <li>• Healthy drinks: Moderate consumption of coffee, green and black tea. Other beverages that can be beneficial include karkadé (hibiscus) tea, pomegranate juice, beetroot juice and cocoa.</li> <li>• Moderation of alcohol consumption: The recommended daily limit for alcohol consumptions is 2 standard drinks for men and 1.5 for women (10 g alcohol/standard drink). Avoid binge drinking.</li> <li>• Weight reduction: Body weight control is indicated to avoid obesity. Particularly abdominal obesity should be managed. Ethnic-specific cut-offs for BMI and waist circumference should be used. Alternatively, a waist-to-height ratio &lt;0.5 is recommended for all populations.</li> <li>• Smoking cessation: Smoking is a major risk factor for cardiovascular disease (CVD), COPD and cancer. Smoking cessation and referral to smoking cessation programs are advised.</li> <li>• Regular physical activity: Studies suggest that regular aerobic and resistance exercise may be beneficial for both the prevention and treatment of hypertension. Moderate intensity aerobic exercise (walking, jogging, cycling, yoga, or swimming) for 30 minutes on five to seven days per week Strength training also can help reduce blood pressure. Performance of resistance/strength exercises on two to three days per week.</li> <li>• Reduce stress and induce mindfulness: Stress should be reduced and mindfulness or meditation introduced into the daily routine.</li> <li>• Reduce exposure to air pollution and cold temperature: Evidence from studies support a negative effect of air pollution on blood pressure in the long-term.</li> </ul> <p><b>Pharmacological Treatment</b></p> <ul style="list-style-type: none"> <li>• Ideal characteristics of drug treatment <ul style="list-style-type: none"> <li>○ Treatments should be evidence-based in relation to morbidity/mortality prevention.</li> <li>○ Use a once-daily regimen which provides 24-hour blood pressure control.</li> <li>○ Treatment should be affordable and/or cost-effective relative to other agents.</li> <li>○ Treatments should be well-tolerated.</li> <li>○ Evidence of benefits of use of the medication in populations to which it is to be applied.</li> </ul> </li> <li>• General scheme for drug treatment <ul style="list-style-type: none"> <li>○ Lifestyle modification is the first line of antihypertensive treatment.</li> <li>○ Grade 1 hypertension (BP 140 to 159/ 90 to 99): Immediate drug treatment in high-risk patients or those with CVD, chronic kidney disease (CKD), diabetes mellitus (DM), or hypertension-mediated organ damage (HMOD). Drug treatment after three to six months of lifestyle intervention if BP still not controlled in low to moderate risk patients.</li> <li>○ Grade 2 hypertension (BP ≥160/100): Immediate drug treatment in all patients.</li> </ul> </li> <li>• Core drug-treatment strategy <ul style="list-style-type: none"> <li>○ Step 1: Dual low-dose combination (ACE inhibitor or ARB plus dihydropyridine-calcium channel blockers (DHP-CCB)); consider monotherapy in low-risk grade 1 hypertension or in very old (≥80 years)</li> </ul> </li> </ul>

Clinical Guideline	Recommendations
	<p>or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance; consider ACE/ARB plus DHP-CCB or DHP-CCB plus thiazide-like diuretics in black patients.</p> <ul style="list-style-type: none"> <li>○ Step 2: Dual full-dose combination (ACE inhibitor or ARB plus DHP-CCB); consider monotherapy in low-risk grade 1 hypertension or in very old (≥80 years) or frail patients; consider ACE/ARB plus thiazide-like diuretic in post-stroke, very elderly, incipient HF, or CCB intolerance.</li> <li>○ Step 3: Triple combination (ACE/ARB plus DHP-CCB plus thiazide-like diuretic).</li> <li>○ Step 4, resistant hypertension: triple combination plus spironolactone or other drug, alternatives include amiloride, doxazosin, eplerenone, clonidine, or β-blocker. Caution with spironolactone or other potassium sparing diuretics when estimated GFR &lt;45 mL/min/1.73m<sup>2</sup> or K<sup>+</sup> &gt;4.5 mmol/L.</li> <li>○ Consider β-blockers at any treatment step when there is a specific indication for their use, e.g., heart failure, angina, post-MI, atrial fibrillation, or younger women planning pregnancy or pregnant.</li> </ul>
<p>Hypertension Canada: 2020 Guidelines for the Prevention, Diagnosis, Risk Assessment, and Treatment of Hypertension in Adults and Children (2020)<sup>32</sup></p>	<p><u>Indications for drug therapy for adults with hypertension without compelling indications for specific agents</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive therapy should be prescribed for average diastolic blood pressure (DBP) measurements of ≥100 mmHg or average systolic blood pressure (SBP) measurements of ≥160 mmHg in patients without macrovascular target organ damage or other cardiovascular risk factors.</li> <li>• Antihypertensive therapy should be strongly considered for average DPB readings ≥90 mmHg or for average SBP readings ≥140 mmHg in the presence of macrovascular target organ damage or other independent cardiovascular risk factors.</li> <li>• For high-risk patients, aged 50 years or older, with SBP levels ≥130 mmHg, intensive management to target a SBP &lt;120 mmHg should be considered. Patient selection for intensive management is recommended and caution should be taken in certain high-risk groups.</li> </ul> <p><u>Indications for drug therapy for adults with diastolic and with or without systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be with either monotherapy or single pill combination (SPC). <ul style="list-style-type: none"> <li>○ Recommended monotherapy choices are: <ul style="list-style-type: none"> <li>▪ A thiazide/thiazide-like diuretic, with longer-acting diuretics preferred;</li> <li>▪ A β-blocker (in patients &lt;60 years of age);</li> <li>▪ An angiotensin-converting enzyme (ACE) inhibitor (in nonblack patients);</li> <li>▪ An angiotensin receptor blocker (ARB); or</li> <li>▪ A long-acting calcium channel blocker (CCB).</li> </ul> </li> <li>○ Recommended SPC choices are those in which an ACE inhibitor is combined with a CCB, ARB with a CCB, or ACE inhibitor or ARB with a diuretic.</li> <li>○ Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> </ul> </li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line choices. Useful choices include a thiazide/thiazide-like diuretic or CCB with either: ACE inhibitor, ARB, or β-blocker. Caution should be exercised in combining a nondihydropyridine CCB and a β-blocker. The combination of an</li> </ul>

Clinical Guideline	Recommendations
	<p>ACE inhibitor and an ARB is not recommended.</p> <ul style="list-style-type: none"> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other antihypertensive drugs may be added.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated hypertension; <math>\beta</math>-blockers are not recommended as first-line therapy for uncomplicated hypertension in patients <math>\geq 60</math> years of age; and ACE inhibitors are not recommended as first-line therapy for uncomplicated hypertension in black patients. However, these agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Indications for drug therapy for adults with isolated systolic hypertension</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should be single-agent therapy with a thiazide/thiazide-like diuretic, a long-acting dihydropyridine CCB, or an ARB. If there are adverse effects, another drug from this group should be substituted. Hypokalemia should be avoided in patients treated with thiazide/thiazide-like diuretic monotherapy.</li> <li>• Additional antihypertensive drugs should be used if target BP levels are not achieved with standard-dose monotherapy. Add-on drugs should be chosen from first-line options.</li> <li>• If BP is still not controlled with a combination of two or more first-line agents, or there are adverse effects, other classes of drugs (such as <math>\alpha</math>-blockers, ACE inhibitors, centrally acting agents, or nondihydropyridine CCBs) may be combined or substituted.</li> <li>• Possible reasons for poor response to therapy should be considered.</li> <li>• <math>\alpha</math>-Blockers are not recommended as first-line agents for uncomplicated isolated systolic hypertension; and <math>\beta</math>-blockers are not recommended as first-line therapy for isolated systolic hypertension in patients <math>\geq 60</math> years of age. However, both agents may be used in patients with certain comorbid conditions or in combination therapy.</li> </ul> <p><u>Guidelines for hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• For most hypertensive patients with CAD, an ACE inhibitor or ARB is recommended.</li> <li>• For hypertensive patients with CAD, but without coexisting systolic heart failure, the combination of an ACE inhibitor and ARB is not recommended.</li> <li>• For high-risk hypertensive patients, when combination therapy is being used, choices should be individualized. The combination of an ACE inhibitor and a dihydropyridine CCB is preferable to an ACE inhibitor and a thiazide/thiazide-like diuretic in selected patients.</li> <li>• For patients with stable angina pectoris but without previous heart failure, myocardial infarction, or coronary artery bypass surgery, either a <math>\beta</math>-blocker or CCB can be used as initial therapy.</li> <li>• Short-acting nifedipine should not be used.</li> <li>• When decreasing SBP to target levels in patients with established CAD (especially if isolated systolic hypertension is present), be cautious when the DBP is <math>\leq 60</math> mmHg because of concerns that myocardial ischemia might be exacerbated, especially in patients with left ventricular hypertrophy (LVH).</li> </ul> <p><u>Guidelines for patients with hypertension who have had a recent myocardial infarction</u></p> <ul style="list-style-type: none"> <li>• Initial therapy should include a <math>\beta</math>-blocker as well as an ACE inhibitor.</li> <li>• An ARB can be used if the patient is intolerant of an ACE inhibitor.</li> <li>• CCBs may be used in patients after myocardial infarction when <math>\beta</math>-blockers are contraindicated or not effective. Nondihydropyridine CCBs should not be used when there is heart failure, evidenced by pulmonary congestion on examination</li> </ul>

Clinical Guideline	Recommendations
	<p>or radiography.</p> <p><u>Treatment of hypertension in association with heart failure</u></p> <ul style="list-style-type: none"> <li>• In patients with systolic dysfunction (ejection fraction &lt;40%), ACE inhibitors and <math>\beta</math>-blockers are recommended for initial therapy. Aldosterone antagonists (mineralocorticoid receptor antagonists) may be combined in treatment for patients with a recent cardiovascular hospitalization, acute myocardial infarction, elevated B-type natriuretic peptide or N-terminal pro-B-type natriuretic peptide level, or New York Heart Association (NYHA) Class II-IV symptoms. Careful monitoring for hyperkalemia is recommended when combining an aldosterone antagonist with ACE inhibitor or ARB treatment. Other diuretics are recommended as additional therapy if needed. Beyond considerations of BP control, doses of ACE inhibitors or ARBs should be titrated to those reported to be effective in trials unless adverse effects become manifest.</li> <li>• An ARB is recommended if ACE inhibitors are not tolerated.</li> <li>• A combination of hydralazine and isosorbide dinitrate is recommended if ACE inhibitors and ARBs are contraindicated or not tolerated.</li> <li>• For hypertensive patients whose BP is not controlled, an ARB may be combined with an ACE inhibitor and other antihypertensive drug treatment. Careful monitoring should be used if combining an ACE inhibitor and an ARB because of potential adverse effects such as hypotension, hyperkalemia, and worsening renal function. Additional therapies may also include dihydropyridine CCBs.</li> <li>• An angiotensin receptor-neprilysin inhibitor (ARNI) should be used in place of an ACE inhibitor or ARB for patients with HFrEF (&lt;40%) who remain symptomatic despite treatment with appropriate dose of guideline directed HF therapy. Eligible patients must have a serum potassium &lt;5.2 mmol/L, an eGFR <math>\leq 30</math> mL/min/1.73m<sup>2</sup> and close surveillance of serum potassium and creatinine.</li> </ul> <p><u>Treatment of hypertension in association with stroke</u></p> <ul style="list-style-type: none"> <li>• BP management in acute ischemic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> <li>• BP management after acute ischemic stroke <ul style="list-style-type: none"> <li>○ Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack.</li> <li>○ After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently &lt;140/90 mmHg.</li> <li>○ Treatment with an ACE inhibitor and thiazide/thiazide-like diuretic combination is preferred.</li> <li>○ For patients with stroke, the combination of an ACE inhibitor and ARB is not recommended.</li> </ul> </li> <li>• BP management in hemorrhagic stroke (onset to 72 hours) <ul style="list-style-type: none"> <li>○ Please refer to Stroke Best Practice recommendations.</li> </ul> </li> </ul> <p><u>Treatment of hypertension in association with LVH</u></p> <ul style="list-style-type: none"> <li>• Hypertensive patients with LVH should be treated with antihypertensive therapy to decrease the rate of subsequent cardiovascular events.</li> <li>• The choice of initial therapy can be influenced by the presence of LVH. Initial therapy can be drug treatment using ACE inhibitors, ARBs, long-acting CCBs, or thiazide/thiazide-like diuretics. Direct arterial vasodilators such as hydralazine or minoxidil should not be used.</li> </ul> <p><u>Treatment of hypertension in association with nondiabetic chronic kidney disease</u></p> <ul style="list-style-type: none"> <li>• Individualize BP targets in patients with chronic kidney disease. Consider intensive targets (SBP &lt;120 mmHg) in appropriate patients.</li> <li>• For patients with hypertension and proteinuric chronic kidney disease (urinary</li> </ul>

Clinical Guideline	Recommendations
	<p>protein &gt;150 mg per 24 hours or albumin to creatinine ratio &gt;30 mg/mmol), initial therapy should be an ACE inhibitor or an ARB if there is intolerance to ACE inhibitors.</p> <ul style="list-style-type: none"> <li>• In most cases, combination therapy with other antihypertensive agents might be needed to reach target BP levels.</li> <li>• The combination of an ACE inhibitor and ARB is not recommended for patients with nonproteinuric chronic kidney disease.</li> </ul> <p><u>Treatment of hypertension in association with renovascular disease</u></p> <ul style="list-style-type: none"> <li>• Patients with hypertension attributable to atherosclerotic renal artery stenosis should be primarily medically managed because renal angioplasty and stenting offers no benefit over optimal medical therapy alone.</li> <li>• Renal artery angioplasty and stenting for atherosclerotic hemodynamically significant renal artery stenosis could be considered for patients with uncontrolled hypertension resistant to maximally tolerated pharmacotherapy, progressive renal function loss, and acute pulmonary edema.</li> <li>• Patients with confirmed renal fibromuscular dysplasia (FMD) should be referred to a hypertension specialist.</li> <li>• Renal artery angioplasty without stenting is recommended for treatment of FMD-related renal artery stenosis. Stenting is not recommended unless needed because of a periprocedural dissection. Surgical revascularization should be considered in cases of complex lesions less amendable to angioplasty, stenosis associated with complex aneurysm, and restenosis despite two unsuccessful attempts of angioplasty.</li> </ul> <p><u>Treatment of hypertension in association with diabetes mellitus</u></p> <ul style="list-style-type: none"> <li>• Persons with diabetes mellitus should be treated to attain SBP of &lt;130 mmHg and DBP of &lt;80 mmHg.</li> <li>• For persons with cardiovascular or kidney disease, including microalbuminuria, or with cardiovascular risk factors in addition to diabetes and hypertension, an ACE inhibitor or an ARB is recommended as initial therapy.</li> <li>• For persons with diabetes and hypertension not included in other guidelines in this section, appropriate choices include (in alphabetical order): ACE inhibitors, ARBs, dihydropyridine CCBs, and thiazide/thiazide-like diuretics.</li> <li>• If target BP levels are not achieved with standard-dose monotherapy, additional antihypertensive therapy should be used. For persons in whom combination therapy with an ACE inhibitor is being considered, a dihydropyridine CCB is preferable to a thiazide/thiazide-like diuretic.</li> </ul> <p><u>Resistant hypertension</u></p> <ul style="list-style-type: none"> <li>• Resistant hypertension is defined as BP above target despite three or more BP-lowering drugs at optimal doses preferably including a diuretic (and usually a renin-angiotensin-aldosterone system blocker and a CCB).</li> <li>• Accurate office and out-of-office BP measurement is essential.</li> <li>• Other reasons for apparent resistant hypertension should be eliminated before diagnosing true resistant hypertension, including nonadherence, white coat effect, and secondary hypertension.</li> <li>• Pharmacotherapy with the additional use of spironolactone, bisoprolol, doxazosin, amiloride, eplerenone, or clonidine with the baseline regimen decreases BP significantly, with the greatest BP-lowering shown with spironolactone.</li> <li>• Patients with resistant hypertension should be referred to providers with expertise in diagnosis and management of hypertension.</li> </ul> <p><u>Hypertension and pediatrics</u></p>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• BP should be measured regularly in children three years of age or older; the auscultatory method is the gold-standard at present.</li> <li>• Initial therapy should be monotherapy, with an ACE inhibitor or ARB (not first-line in black children), or a long-acting dihydropyridine CCB.</li> <li>• The treatment goal is systolic and diastolic office BP and/or ABPM &lt; 95th percentile or &lt;90<sup>th</sup> percentile in children with risk factors or target organ damage.</li> <li>• Complex cases should be referred to an expert in pediatric hypertension.</li> </ul> <p><u>Hypertension and pregnancy</u></p> <ul style="list-style-type: none"> <li>• Up to 7% of pregnancies are complicated by a hypertensive disorder of pregnancy, and approximately 5% of women will have chronic hypertension when they become pregnant.</li> <li>• The prevalence of hypertension in pregnancy is expected to increase with women becoming pregnant later in their reproductive years and the increasing prevalence of cardiovascular comorbidities such as increased preconception body mass index and maternal diabetes.</li> <li>• The possibility of pregnancy should be considered when managing women with hypertension who are of reproductive age.</li> <li>• Preconception counselling should be offered to all women with hypertension who are considering pregnancy.</li> <li>• ACE inhibitor and ARB therapy should be avoided before conception and during pregnancy unless there is a compelling indication for their use (i.e., proteinuric kidney disease).</li> <li>• Hypertension during pregnancy can increase the risk of adverse maternal and fetal outcomes, including an increased risk of preeclampsia, placental abruption, prematurity, small for gestational age infants, stillbirth, and maternal renal and retinal injury, thus generally requires involvement of an interdisciplinary team including obstetrical care providers.</li> <li>• Antihypertensive therapy is recommended for average SBP measurements of <math>\geq 140</math> mmHg or DBP measurements of <math>\geq 90</math> mmHg in pregnant women with chronic hypertension, gestational hypertension, or preeclampsia. Initial antihypertensive therapy should be monotherapy from the following first-line drugs: oral labetalol, oral methyl dopa, long-acting oral nifedipine, or other oral b-blockers (acebutolol, metoprolol, pindolol, and propranolol). Other antihypertensive drugs can be considered as second-line drugs including: clonidine, hydralazine, and thiazide diuretics.</li> <li>• Women with severe hypertension with SBP <math>\geq 160</math> mmHg or DBP <math>\geq 110</math> mmHg in pregnancy or postpartum require urgent antihypertensive therapy because it is considered an obstetrical emergency.</li> <li>• Antihypertensive drugs used in breastfeeding women include: labetalol, methyl dopa, long-acting nifedipine, enalapril, or captopril.</li> </ul>
<p>European Society of Hypertension/ European Society of Cardiology: <b>2018 Guidelines for the management of arterial hypertension (2018)</b><sup>33</sup></p>	<p><u>Treatment strategies and choice of antihypertensive drugs</u></p> <ul style="list-style-type: none"> <li>• Diuretics (including thiazides, chlorthalidone, and indapamide), <math>\beta</math>-blockers, calcium channel blocker (CCB), angiotensin-converting enzyme (ACE) inhibitors, and angiotensin receptor blockers (ARBs) are all suitable for the initiation and maintenance of antihypertensive treatment, either as monotherapy or in some combinations.</li> <li>• Some agents should be considered as the preferential choice in specific conditions because used in trials in those conditions or because of greater effectiveness in specific types of organ damage. Preferred combinations should comprise a renin-angiotensin system (RAS) blocker (either an ACE inhibitor or an ARB) with a CCB or diuretic.</li> <li>• It is recommended that beta-blockers are combined with any of the other major drug classes when there are specific clinical situations, e.g. angina, post-myocardial infarction, heart failure, or heart rate control.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Initiation of antihypertensive therapy with a two-drug combination may be considered in patients with markedly high baseline blood pressure (BP) or at high cardiovascular (CV) risk.</li> <li>• The combination of two antagonists of the RAS is not recommended and should be discouraged.</li> <li>• Other drug combinations should be considered and probably are beneficial in proportion to the extent of BP reduction. However, combinations that have been successfully used in trials may be preferable.</li> <li>• Combinations of two antihypertensive drugs at fixed doses in a single tablet may be recommended and favored, because reducing the number of daily pills improves adherence, which is low in patients with hypertension. Exceptions are frail older patients and those at low risk and with grade one hypertension (particularly if systolic BP is &lt;150 mmHg).</li> <li>• It is recommended that if BP is not controlled with a three-drug combination, treatment should be increased by the addition of spironolactone or, if not tolerated, other diuretics such as amiloride or higher doses of other diuretics, a beta-blocker, or an alpha-blocker.</li> </ul> <p><u>Treatment strategies in white-coat and masked hypertension</u></p> <ul style="list-style-type: none"> <li>• In white-coat hypertensives without additional risk factors, therapeutic intervention may be limited to lifestyle changes only, but this decision should be accompanied by close follow-up.</li> <li>• In white-coat hypertensives with a higher CV risk or hypertension-mediated organ damage, drug treatment may be considered in addition to lifestyle changes.</li> <li>• In masked hypertension, both lifestyle measures and antihypertensive drug treatment should be considered, because this type of hypertension has been consistently found to have a CV risk very close to that of in- and out-of-office hypertension.</li> <li>• Antihypertensive drug up-titration should be considered in treated patients whose out-of-office BP is not controlled (i.e., masked uncontrolled hypertension), because of the high CV risk of these patients.</li> </ul> <p><u>Antihypertensive treatment strategies in the elderly</u></p> <ul style="list-style-type: none"> <li>• It is recommended that older patients (<math>\geq 65</math> years) are treated with the same recommendations in non-older patient population. In very old patients (<math>\geq 80</math> years), it may be appropriate to initiate treatment with monotherapy.</li> <li>• In all older patients, when combination therapy is used, it is recommended that this is initiated at the lowest available doses. In all older patients, and especially very old or frail patients, the possible occurrence of postural BP should be closely monitored and symptoms of possible hypotensive episodes checked by ambulatory blood pressure monitoring.</li> <li>• Unless required for concomitant diseases, loop diuretics and alpha-blockers should be avoided because of their association with injurious falls.</li> <li>• Renal function should be frequently assessed to detect possible increases in serum creatinine and reductions in estimated glomerular filtration rate (eGFR) as a result of BP-related reductions in renal perfusion.</li> <li>• When treated, BP should be lowered to a systolic value of 130 to 139 mmHg and a diastolic value of &lt;80 mmHg if tolerated. Treated values of &lt;130 mmHg should be avoided.</li> </ul> <p><u>Treatment strategies in hypertensive women</u></p> <ul style="list-style-type: none"> <li>• Hormone therapy and selective estrogen receptor modulators are not recommended and should not be used for primary or secondary prevention of CVD.</li> <li>• In women with gestational hypertension, pre-existing hypertension superimposed</li> </ul>

Clinical Guideline	Recommendations
	<p>by gestational hypertension, or with hypertension and subclinical organ damage or symptoms, initiation of drug treatments is recommended when SBP is <math>\geq 140</math> mmHg or DBP <math>\geq 90</math> mmHg. In all other cases, initiation of drug treatment is recommended when SBP is <math>\geq 150</math> mmHg or DBP is <math>\geq 95</math> mmHg.</p> <ul style="list-style-type: none"> <li>• Methyldopa, labetalol, and CCBs are recommended as the drugs of choice for the treatment of hypertension in pregnancy.</li> <li>• ACE inhibitors, ARBs, or direct renin inhibitors are not recommended during pregnancy.</li> <li>• SBP <math>\geq 170</math> mmHg or DBP <math>\geq 110</math> mmHg in a pregnant woman is an emergency, and admission to hospital is recommended.</li> <li>• In severe hypertension, drug treatment with intravenous (IV) labetalol, oral methyldopa, or nifedipine is recommended.</li> <li>• The recommended treatment for hypertensive crisis is IV labetalol or nicardipine and magnesium.</li> <li>• In pre-eclampsia associated with pulmonary edema, nitroglycerin given as an IV infusion is recommended.</li> <li>• In women with gestational hypertension or mild-pre-eclampsia, delivery is recommended at 37 weeks.</li> <li>• It is recommended to expedite delivery in pre-eclampsia with adverse conditions, such as visual disturbances or hemostatic disorders</li> <li>• In women at high risk of pre-eclampsia, provided they are at low risk of gastrointestinal hemorrhage, treatment with low dose aspirin from 12 weeks until delivery may be considered.</li> <li>• Methyldopa, labetalol, and nifedipine should be considered preferential antihypertensive drugs in pregnancy. Intravenous labetalol or infusion of nitroprusside should be considered in case of emergency (pre-eclampsia).</li> </ul> <p><u>Treatment strategies in patients with diabetes</u></p> <ul style="list-style-type: none"> <li>• Antihypertensive drug treatment is recommended for people with diabetes when office BP is <math>\geq 140/90</math> mmHg.</li> <li>• A SBP goal <math>&lt; 130</math> mmHg is recommended in patients with diabetes and <math>&lt; 130</math> mmHg if tolerated, but not <math>&lt; 120</math> mmHg.</li> <li>• In older people, the target SBP range is 130 to 139 mmHg.</li> <li>• The DBP target in patients with diabetes is recommended to be <math>&lt; 80</math> mmHg, but not <math>&lt; 70</math> mmHg.</li> <li>• It is recommended to initiate treatment with a combination of a RAS blocker with a CCB or thiazide/thiazide-like diuretic.</li> <li>• It is recommended that individual drug choice takes comorbidities into account.</li> <li>• Simultaneous administration of two blockers of the RAS is not recommended and should be avoided in patients with diabetes.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with nephropathy</u></p> <ul style="list-style-type: none"> <li>• In patients with diabetic and non-diabetic CKD, it is recommended that an office BP of <math>\geq 140/90</math> mmHg be treated with lifestyle advice and BP-lowering medication.</li> <li>• In patients with diabetic or non-diabetic CKD, it is recommended to lower SBP to a range of 130 to 139 mmHg. And individualized treatments should be considered according to its tolerability and impact on renal function and electrolytes.</li> <li>• A combination of a RAS blocker with a CCB or a diuretic is recommended as initial therapy.</li> <li>• RAS blockers are more effective in reducing albuminuria than other antihypertensive agents, and are indicated in hypertensive patients in the presence of microalbuminuria or overt proteinuria.</li> <li>• Combination of two RAS blockers, though potentially more effective in reducing</li> </ul>

Clinical Guideline	Recommendations
	<p>proteinuria, is not recommended.</p> <p><u>Therapeutic strategies in hypertensive patients with cerebrovascular disease</u></p> <ul style="list-style-type: none"> <li>• In patients with acute intracerebral hemorrhage, immediate BP lowering is not recommended for patients with SBP &lt;220 mmHg. In patients with SBP <math>\geq</math>220 mmHg, care acute BP lowering with IV therapy to &lt;180 mmHg should be considered.</li> <li>• In acute ischemic stroke, routine BP lowering with antihypertensive therapy is not recommended with the exceptions with the exceptions: in patients with acute ischemic stroke who are eligible for IV thrombolysis, BP should be carefully lowered and maintained at &lt;180/105 mmHg for at least the first 24 hours after thrombolysis; In patients with markedly elevated BP who do not receive fibrinolysis, drug therapy may be considered, based on clinical judgement, to reduce BP by 15% during the first 24 hours after the stroke onset.</li> <li>• In hypertensive patients with an acute cerebrovascular event, antihypertensive treatment is recommended immediately for transient ischemic attack (TIA) and after several days in ischemic stroke.</li> <li>• In all hypertensive patients with ischemic stroke or TIA, an SBP target range of 120 to 130 mmHg should be considered.</li> <li>• The recommended antihypertensive drug treatment strategy for stroke prevention is a RAS blocker plus a CCB or a thiazide-like diuretic.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with heart failure (HF) or left ventricular hypertrophy (LVH)</u></p> <ul style="list-style-type: none"> <li>• In hypertensive patients with heart failure (with reduced or preserved ejection fraction), BP-lowering treatment should be considered if <math>\geq</math>140/90 mmHg.</li> <li>• In patients with HFrEF, it is recommended that BP-lowering treatment comprises an ACE inhibitor or ARB, and a beta-blocker and a diuretic and/or mineralocorticoid receptor antagonist (MRA) if required.</li> <li>• Dihydropyridine CCBs may be added if BP control is not achieved.</li> <li>• In patients with HFpEF, BP treatment threshold and target values should be the same as for HFrEF).</li> <li>• Because no specific drug has proven its superiority, all major agents can be used.</li> <li>• In all patients with LVH, it is recommended to treat with a RAS blocker or in combination with a CCB or diuretic and SBP should be lowered to a range of 120 to 130 mmHg.</li> </ul> <p><u>Therapeutic strategies in hypertensive patients with coronary artery disease (CAD)</u></p> <ul style="list-style-type: none"> <li>• In patients with CAD receiving BP-lowering drugs, it is recommended to target SBP to <math>\leq</math>130 mmHg if tolerated, but not &lt;120 mmHg. In older patients, the target is an SBP range of 130 to 140 mmHg. The target DBP is &lt;80 mmHg, but not &lt;70 mmHg.</li> <li>• In hypertensive patients with a history of myocardial infarction, beta-blockers and RAS blockers are recommended as part of treatment.</li> <li>• In patients with asymptomatic angina, beta-blockers and/or CCBs are recommended.</li> </ul>
<p>National Institute for Health and Clinical Excellence: <b>Hypertension in adults: diagnosis and management (2019)</b><sup>34</sup></p>	<p><u>Choosing antihypertensive drug treatment (for people with or without type II diabetes)</u></p> <ul style="list-style-type: none"> <li>• Where possible, recommend treatment with drugs taken only once a day.</li> <li>• Prescribe non-proprietary drugs where these are appropriate and minimize cost.</li> <li>• Offer people with isolated systolic hypertension (systolic blood pressure <math>\geq</math>160 mmHg) the same treatment as people with both raised systolic and diastolic blood pressure.</li> <li>• Offer antihypertensive drug treatment to women of child-bearing potential with</li> </ul>

Clinical Guideline	Recommendations
	<p>diagnosed hypertension in line with recommendations in this guideline. For women considering pregnancy or who are pregnant or breastfeeding, manage hypertension in line with the recommendations on Management of pregnancy with chronic hypertension and Breastfeeding in 'Hypertension in pregnancy'.</p> <ul style="list-style-type: none"> <li>• When choosing antihypertensive drug treatment for adults of black African or African-Caribbean family origin, consider an angiotensin II receptor blocker, in preference to an angiotensin-converting enzyme inhibitor.</li> </ul> <p><u>Step one treatment</u></p> <ul style="list-style-type: none"> <li>• Patients &lt;55 years of age should be offered a step one antihypertensive with an angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB).</li> <li>• Offer an ACE inhibitor or an ARB to adults starting step 1 antihypertensive treatment who have type II diabetes and are of any age or family origin or those aged &lt;55 years but not of black African or African-Caribbean family origin.</li> <li>• If an ACE inhibitor is not tolerated, offer an ARB.</li> <li>• Do not combine an ACE inhibitor with an ARB for the treatment of hypertension.</li> <li>• Offer a calcium channel blocker (CCB) to adults starting step 1 antihypertensive treatment who are &gt;55 years of age and do not have diabetes and are of black African or African-Caribbean family origin and do not have type II diabetes and of any age.</li> <li>• If a CCB is not suitable, for example because of edema or intolerance, or if there is evidence of heart failure or a high risk of heart failure, offer a thiazide-like diuretic.</li> <li>• If diuretic treatment is to be initiated or changed, offer a thiazide-like diuretic, such as indapamide in preference to a conventional thiazide diuretic such as bendroflumethiazide or hydrochlorothiazide.</li> <li>• For adults with hypertension who are already receiving treatment with bendroflumethiazide or hydrochlorothiazide, who have stable, well-controlled blood pressure, continue with their treatment.</li> </ul> <p><u>Step two treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering next step treatment for hypertension discuss with the person if they are taking their medicine as prescribed and support adherence in line with NICE's guideline on "Medicines adherence: involving patients decisions about prescribed medicines and supporting adherence".</li> <li>• If hypertension is not controlled with a step one treatment of an ACE inhibitor or ARB, offer choice of one of the following drugs in addition to the step one treatment: a CCB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults taking step one treatment of a CCB, offer the choice of one of the following drugs in addition to the step one treatment: an ACE inhibitor or an ARB or a thiazide-like diuretic.</li> <li>• If hypertension is not controlled in adults of black African or African-Caribbean family origin who do not have type 2 diabetes taking step one treatment, consider an ARB, in preference to an ACE inhibitor, in addition to step one treatment.</li> </ul> <p><u>Step three treatment</u></p> <ul style="list-style-type: none"> <li>• Before considering step three treatment, review the person's medications to ensure they are being taken at the optimal doses and discuss adherence (see recommendation under step two).</li> <li>• If hypertension is not controlled in adults taking step two treatment, offer a combination of an ACE inhibitor or ARB and a CCB and a thiazide-like diuretic.</li> </ul> <p><u>Step four treatment</u></p>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• If hypertension is not controlled in adults taking the optimal tolerated doses of an ACE inhibitor or an ARB plus a CCB and a thiazide-like diuretic, regard them as having resistant hypertension.</li> <li>• Before considering further treatment for a person with resistant hypertension, confirm elevated clinic blood pressure measurements using ambulatory or home blood pressure recordings, assess for postural hypotension, and discuss adherence.</li> <li>• For people with confirmed resistant hypertension, consider adding a fourth antihypertensive drug as step four treatment or seeking specialist advice.</li> <li>• Consider further diuretic therapy with low-dose spironolactone for adults with resistant hypertension starting step four treatment who have a blood potassium level of 4.5 mmol/l or less. Use particular caution in people with a reduced estimated glomerular filtration rate because they have an increased risk of hyperkalemia.</li> <li>• When using further diuretic therapy for step four treatment of resistant hypertension, monitor blood sodium and potassium and renal function within one month of starting treatment and repeat as needed thereafter.</li> <li>• Consider an alpha-blocker or beta-blocker for adults with resistant hypertension starting step four treatment who have a blood potassium level of more than 4.5 mmol/l.</li> <li>• If blood pressure remains uncontrolled in people with resistant hypertension taking the optimal tolerated doses of four drugs, seek specialist advice.</li> </ul>
<p>International Society on Hypertension in Blacks: <b>Management of High Blood Pressure in Blacks (2010)</b><sup>35</sup></p>	<ul style="list-style-type: none"> <li>• To attain and maintain blood pressure (BP) below target levels, multiple antihypertensive drugs will be required in most hypertensive blacks.</li> <li>• Use of two-drug combination therapy when SBP is &gt;15 mm Hg and/or DBP is &gt;10 mm Hg above goal levels is increasingly recommended as first-line therapy.</li> <li>• Two-drug regimens have generally contained a thiazide-type diuretic; however, the combination of a calcium channel blocker (CCB) with either an ACE inhibitor or an ARB has been shown equally efficacious in BP lowering but with demonstrated superiority (CCB+ACE) for hard clinical outcomes compared with the same ACE inhibitor plus a thiazide-type diuretic.</li> <li>• In secondary prevention patients, the combination therapy should include a drug(s) with the appropriate compelling indications.</li> <li>• Certain classes of antihypertensive medications, specifically diuretics and CCBs, lower BP on average more than <math>\beta</math>-blockers and renin-angiotensin system (RAS) blockers in black patients when used as monotherapies.</li> <li>• In the absence of compelling indications, when BP is near goal levels, monotherapy with a diuretic or a CCB is preferred.</li> <li>• Lifestyle modifications should be initiated in all patients with hypertension, whether or not pharmacotherapy is planned.</li> <li>• ACE inhibitors or ARBs are recommended as alternative monotherapy options in the treatment of hypertension in blacks. The rationale for their lower tier monotherapy recommendation is because they have consistently achieved lesser average reductions in BP relative to that observed with monotherapy using either a diuretic or CCB.</li> </ul>
<p>Kidney Disease Improving Clinical Outcomes Group; <b>KDIGO Clinical Practice Guideline for the Management of Blood Pressure in Chronic Kidney Disease</b></p>	<p><u>Blood pressure measurement</u></p> <ul style="list-style-type: none"> <li>• The Work Group recommends standardized office blood pressure (BP) measurement in preference to routine office BP measurements for the management of high BP in adults.</li> <li>• The Work Group suggests that out-of-office BP measurements with ambulatory BP monitoring (ABPM) or home BP monitoring (HBPM) be used to complement standardized office BP readings for the management of high BP.</li> </ul> <p><u>Lifestyle interventions for lowering BP in patients with chronic kidney disease</u></p>

Clinical Guideline	Recommendations
<p><b>(2021)</b><sup>36</sup></p>	<p><u>(CKD) not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests targeting a sodium intake &lt;2 grams of sodium per day (or &lt;90 mmol of sodium per day, or &lt;5 grams of sodium chloride per day) in patients with high BP and CKD.</li> <li>The Work Group suggests that patients with high BP and CKD be advised to undertake moderate-intensity physical activity for a cumulative duration of at least 150 minutes per week, or to a level compatible with their cardiovascular and physical tolerance.</li> </ul> <p><u>BP management in patients with CKD, with or without diabetes, not receiving dialysis</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests that adults with high BP and CKD be treated with a target systolic BP (SBP) of &lt;120 mmHg, when tolerated, using standardized office BP measurement.</li> <li>The Work Group recommends starting renin-angiotensin-system inhibitors (RASi) (angiotensin-converting enzyme inhibitor [ACEi] or angiotensin II receptor blocker [ARB]) for people with high BP, CKD, and severely increased albuminuria without diabetes.</li> <li>The Work Group suggests starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately increased albuminuria without diabetes.</li> <li>The Work Group recommends starting RASi (ACEi or ARB) for people with high BP, CKD, and moderately-to-severely increased albuminuria with diabetes.</li> <li>The Work Group recommends avoiding any combination of ACEi, ARB, and direct renin inhibitor (DRI) therapy in patients with CKD, with or without diabetes.</li> </ul> <p><u>BP management in kidney transplant recipients</u></p> <ul style="list-style-type: none"> <li>Treat adult kidney transplant recipients with high BP to a target BP of &lt;130 mmHg systolic and &lt;80 mmHg diastolic using standardized office BP measurement.</li> <li>The Work Group recommends that a dihydropyridine calcium channel blocker (CCB) or an ARB be used as the first-line antihypertensive agent in adult kidney transplant recipients.</li> </ul> <p><u>BP management in children with CKD</u></p> <ul style="list-style-type: none"> <li>The Work Group suggests that in children with CKD, 24-hour mean arterial pressure by ABPM should be lowered to &lt;50<sup>th</sup> percentile for age, sex, and height.</li> </ul>
<p>American College of Cardiology/ American Heart Association Task Force: <b>Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults</b> (2017)<sup>37</sup></p>	<p><u>Initiation of Blood Pressure (BP) Treatment for Overall Cardiovascular Disease (CVD) Risk</u></p> <ul style="list-style-type: none"> <li>Use of BP-lowering medications is recommended for secondary prevention of recurrent CVD events in patients with clinical CVD and an average systolic blood pressure (SBP) <math>\geq 130</math> mmHg or an average diastolic blood pressure (DBP) of <math>\geq 80</math> mmHg and for primary prevention in adults with an estimated 10-year atherosclerotic cardiovascular disease (ASCVD) risk of <math>\geq 10\%</math> and an average SBP of <math>\geq 130</math> mmHg or an average <math>\geq 80</math> mmHg.</li> <li>Use of BP-lowering medication is recommended for primary prevention of CVD in adults with no history of CVD and with an estimated 10-year ASCVD risk &lt;10% and an SBP of <math>\geq 140</math> mmHg or a DBP of <math>\geq 90</math> mmHg.</li> <li>Simultaneous use of an angiotensin converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), and/or renin inhibitor is potentially harmful and is not recommended to treat adults with hypertension.</li> <li>For adults with confirmed hypertension and known CVD or 10-year ASCVD risk of <math>\geq 10\%</math>, a BP target &lt;130/80 mmHg is recommended. For adults with confirmed hypertension without additional markers of increased CVD risk, a BP target &lt;130/80 mmHg may be reasonable.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• For initiation of antihypertensive drug therapy, first-line agents include thiazide diuretics, calcium channel blockers (CCBs), and ACE inhibitors or ARBs.</li> <li>• Initiation of antihypertensive drug therapy with two first-line agents of different classes, either as separate agents or in a fixed-dose combination, is recommended in adults with stage 2 hypertension and an average BP &gt;20/10 mmHg above their BP target.</li> <li>• Initiation of antihypertensive drug therapy with a single antihypertensive drug is reasonable in adults with stage 1 hypertension and BP goal &lt;130/80 mmHg with dosage titration and sequential addition of other agents to achieve the BP target.</li> </ul> <p><u>Stable Ischemic Heart Disease (SIHD)</u></p> <ul style="list-style-type: none"> <li>• In adults with SIHD and hypertension, a BP target &lt;130/80 is recommended.</li> <li>• Adults with SIHD and hypertension (BP <math>\geq</math>130/80 mmHg) should be treated with medications [e.g., guideline-directed medical therapy (GDMT) beta-blockers, ACE inhibitors, or ARBs] for compelling indications [e.g., previous myocardial infarction (MI), stable angina] as first-line therapy, with the addition of other drugs (e.g., dihydropyridine CCBs, thiazide diuretics, and/or mineralocorticoid receptor antagonists) as needed to further control hypertension.</li> <li>• In adults with SIHD with angina and persistent uncontrolled hypertension, the addition of dihydropyridine CCBs to GDMT beta-blockers is recommended.</li> <li>• In adults who have had a MI or acute coronary syndrome, it is reasonable to continue GDMT beta-blockers beyond three years as long-term therapy for hypertension.</li> <li>• Beta-blockers and/or CCBs might be considered to control hypertension in patients with coronary artery disease (CAD) had an MI more than three years ago and have angina.</li> </ul> <p><u>Heart Failure</u></p> <ul style="list-style-type: none"> <li>• In adults with increased risk of HF, the optimal BP in those with hypertension should be &lt;130 mmHg.</li> <li>• Adults with HFrEF and hypertension should be prescribed GDMT titrated to attain a BP &lt;130/80 mmHg.</li> <li>• Non-dihydropyridine CCBs are not recommended in the treatment of hypertension in adults with HFrEF.</li> <li>• In adults with HFpEF who present with symptoms of volume overload, diuretics should be prescribed to control hypertension.</li> <li>• Adults with HFpEF and persistent hypertension after management of volume overload should be prescribed ACE inhibitors or ARBs and beta-blockers titrated to attain SBP &lt;130 mmHg.</li> </ul> <p><u>CKD</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and CKD should be treated to a BP goal &lt;130/80 mmHg.</li> <li>• In adults with hypertension and CKD [stage 3 or higher or stage 1 or 2 with albuminuria (<math>\geq</math>300 mg/d, or <math>\geq</math>300 mg/g albumin-to-creatinine ratio or the equivalent in the first morning void)], treatment with an ACE inhibitor is reasonable to slow kidney disease progression. Treatment with an ARB may be reasonable if an ACE inhibitor is not tolerated.</li> <li>• After kidney transplantation, it is reasonable to treat patients with hypertension to a BP goal &lt;130/80 mmHg and with a CCB on the basis of improved glomerular filtration rate (GFR) and kidney survival.</li> </ul> <p><u>Cerebrovascular Disease</u></p> <ul style="list-style-type: none"> <li>• In adults with intracerebral hemorrhage (ICH) who present with SBP &gt;220 mmHg, it is reasonable to use continuous intravenous (IV) drug infusion and</li> </ul>

Clinical Guideline	Recommendations
	<p>close BP monitoring to lower levels. Immediate lowering of SBP to &lt;140 mmHg in adults with spontaneous ICH who present within six hours of the acute event and have an SBP between 150 mmHg and 220 mmHg is not of benefit to reduce death or severe disability and can be potentially harmful.</p> <ul style="list-style-type: none"> <li>• Adults with acute ischemic stroke and elevated BP who are eligible for treatment with IV tissue plasminogen activator (tPA) should have their BP slowly lowered to &lt;185/110 mmHg before thrombolytic therapy is initiated.</li> <li>• In adults with an acute ischemic stroke, BP should be &lt;185/110 mmHg before administration of IV tPA and should be maintained below 180/105 mmHg for at least the first 24 hours after initiation drug therapy.</li> <li>• Starting or restarting antihypertensive therapy during hospitalization in patients with BP &gt;140/90 mmHg who are neurologically stable is safe and reasonable to improve long-term BP control, unless contraindicated.</li> <li>• In patient with BP <math>\geq</math>220/120 mmHg who did not receive IV alteplase or endovascular treatment and have no comorbid conditions requiring acute antihypertensive treatment, the benefit of initiating or reinitiating treatment of hypertension within the first 48 to 72 hours is uncertain. It might be reasonable to lower BP by 15% during the first 24 hours after onset of stroke. In patients with BP &lt;220/120 mmHg with the same conditions, initiating or reinitiating treatment of hypertension within the first 48 to 72 hours after an acute ischemic stroke is not effective to prevent death or dependency.</li> <li>• Adults with previously treated stroke or transient ischemic attack should be restarted on antihypertensive treatment after the first few days of the index event to reduce the risk of recurrent stroke and other vascular events. Treatment with a thiazide diuretic, ACE inhibitor, or ARB, or combination treatment consisting of a thiazide diuretic plus ACE inhibitor, is useful.</li> <li>• Adults not previously treated for hypertension who experienced a stroke or transient ischemic attack and have an established BP <math>\geq</math>140/90 mmHg should be prescribed antihypertensive treatment a few days after the index event to reduce the risk of recurrent stroke and other vascular event.</li> <li>• For adults who experience a stroke or transient ischemic attack, selection of specific drugs should be individualized on the basis of patient comorbidities and agent pharmacological class.</li> <li>• For adults who experience a stroke or transient ischemic attack, a BP goal &lt;130/80 mmHg may be reasonable.</li> <li>• For adults with a lacunar stroke, a target SBP goal &lt;130 mmHg may be reasonable.</li> <li>• In adults previously untreated for hypertension who experience an ischemic stroke or transient ischemic attack and have an SBP &lt;140 mmHg and a DBP &lt;90 mmHg, the usefulness of initiating antihypertensive treatment is not well established.</li> </ul> <p><u>Peripheral Artery Disease (PAD)</u></p> <ul style="list-style-type: none"> <li>• Adults with hypertension and PAD should be treated similarly to patients with hypertension without PAD.</li> </ul> <p><u>Diabetes Mellitus (DM)</u></p> <ul style="list-style-type: none"> <li>• In adults with DM and hypertension, antihypertensive drug treatment should be initiated at a BP of <math>\geq</math>130/80 mmHg with a treatment goal &lt;130/80 mmHg.</li> <li>• In adults with DM and hypertension, all first-line classes of antihypertensive agents (i.e., diuretics, ACE inhibitors, ARBs, and CCBs) are useful and effective.</li> <li>• In adults with DM and hypertension, ACE inhibitors or ARBs may be considered in the presence of albuminuria.</li> </ul> <p><u>Atrial Fibrillation, Valvular Heart Disease, and Aortic disease</u></p>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• Treatment of hypertension can be useful for prevention of recurrence of AF.</li> <li>• In adults with asymptomatic aortic stenosis, hypertension should be treated with pharmacotherapy, starting at a low dose and gradually titrating upward as needed.</li> <li>• In patients with chronic aortic insufficiency, treatment of systolic hypertension with agents that do not slow the heart rate (i.e., avoid beta-blockers) is reasonable.</li> <li>• Beta-blockers are recommended as the preferred antihypertensive agents in patients with hypertension and thoracic aortic disease.</li> </ul> <p><u>Racial and Ethnic Differences in Treatment</u></p> <ul style="list-style-type: none"> <li>• In black adults with hypertension but without HF or CKD, including those with DM, initial antihypertensive treatment should include a thiazide-type diuretic or CCB. Two or more antihypertensive medications are recommended to achieve a BP target &lt;130/80 mmHg in most adults with hypertension, especially in black adults with hypertension.</li> </ul> <p><u>Pregnancy</u></p> <ul style="list-style-type: none"> <li>• Women with hypertension who become pregnant, or are planning to become pregnant, should be transitioned to methyldopa, nifedipine, and/or labetalol during pregnancy.</li> <li>• Women with hypertension who become pregnant should not be treated with ACE inhibitors, ARBs, or direct renin inhibitors.</li> </ul> <p><u>Older Persons</u></p> <ul style="list-style-type: none"> <li>• Treatment of hypertension with an SBP treatment goal &lt;130 mmHg is recommended for noninstitutionalized ambulatory community-dwelling adults (≥65 years of age) with an average SBP of ≥130 mmHg.</li> <li>• For older adults (≥65 years of age) with hypertension and a higher burden of comorbidity and limited life expectancy, clinical judgment, patient preference, and a team-based approach to assess risk/benefit is reasonable for decisions regarding intensity of BP lowering and choice of antihypertensive drugs.</li> </ul> <p><u>Hypertensive Crises</u></p> <ul style="list-style-type: none"> <li>• In adults with a hypertensive emergency, admission to an intensive care unit is recommended for continuous monitoring of BP and target organ damage and for parenteral administration of an appropriate agent.</li> <li>• For adults with a compelling condition (i.e., aortic dissection, severe pre-eclampsia or eclampsia, or pheochromocytoma crisis), SBP should be reduced to &lt;140 mmHg during the first hour and to &lt;120 mmHg in aortic dissection.</li> <li>• For adults without a compelling condition, SBP should be reduced by no more than 25% within the first hours; then, if stable, to 160/100 mmHg within the next two to six hours; and then cautiously to normal during the following 24 to 48 hours.</li> </ul> <p><u>Cognitive Decline and Dementia</u></p> <ul style="list-style-type: none"> <li>• In adults with hypertension, BP lowering is reasonable to prevent cognitive decline and dementia.</li> </ul> <p><u>Patients Undergoing Surgical Procedures</u></p> <ul style="list-style-type: none"> <li>• In patients with hypertension undergoing major surgery who have been on beta-blockers chronically, beta-blockers should be continued.</li> <li>• In patients with hypertension undergoing planned elective major surgery, it is reasonable to continue medical therapy for hypertension until surgery.</li> <li>• In patients with hypertension undergoing major surgery, discontinuation of ACE inhibitors or ARBs perioperatively may be considered.</li> </ul>

Clinical Guideline	Recommendations
	<ul style="list-style-type: none"> <li>• In patients with planned elective major surgery and SBP <math>\geq</math>180 mmHg or DBP <math>\geq</math>110 mmHg, deferring surgery may be considered.</li> <li>• For patients undergoing surgery, abrupt pre-operative discontinuation of beta-blockers or clonidine is potentially harmful.</li> <li>• Beta-blockers should not be started on the day of surgery in beta-blocker-naïve patients.</li> <li>• Patients with intraoperative hypertension should be managed with IV medications until such time as oral medications can be resumed.</li> </ul>
<p>American Diabetes Association: <b>Standards of Medical Care in Diabetes (2022)</b><sup>38</sup></p>	<p><b>Hypertension/blood pressure control</b></p> <ul style="list-style-type: none"> <li>• Blood pressure should be measured at every routine visit. When possible, patients found to have elevated blood pressure (<math>\geq</math>140/90) should have blood pressure confirmed using multiple readings, including measurements on a separate day, to diagnose hypertension. Patients with blood pressure <math>\geq</math>180/110 and cardiovascular disease could be diagnosed with hypertension at a single visit.</li> <li>• All hypertensive patients with diabetes should monitor their blood pressure at home.</li> <li>• For patients with diabetes and hypertension, with diabetes and hypertension, blood pressure targets should be individualized through a shared decision-making process that addresses cardiovascular risk, potential adverse effects of antihypertensive medications, and patient preferences.</li> <li>• For individuals with diabetes and hypertension at higher cardiovascular risk (existing atherosclerotic cardiovascular disease [ASCVD] or 10-year ASCVD risk <math>\geq</math>15%), a blood pressure target of <math>&lt;</math>130/80 mmHg may be appropriate, if it can be safely attained.</li> <li>• For individuals with diabetes and hypertension at lower risk for cardiovascular disease (10-year atherosclerotic cardiovascular disease risk <math>&lt;</math>15%), treat to blood pressure target of <math>&lt;</math>140/90.</li> <li>• In pregnant patients with diabetes and preexisting hypertension, a blood pressure target of 110 to 135/85 is suggested in the interest of reducing the risk for accelerated maternal hypertension and minimizing impaired fetal growth.</li> <li>• For patients with blood pressure <math>&gt;</math>120/80, lifestyle intervention consists of weight loss when indicated, a Dietary Approaches to Stop Hypertension (DASH)-style eating pattern including reducing sodium and increasing potassium intake, moderation of alcohol intake, and increased physical activity.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq</math>140/90 mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of pharmacologic therapy to achieve blood pressure goals.</li> <li>• Patients with confirmed office-based blood pressure <math>\geq</math>160/100 mmHg should, in addition to lifestyle therapy, have prompt initiation and timely titration of two drugs or a single pill combination of drugs demonstrated to reduce cardiovascular events in patients with diabetes.</li> <li>• Treatment for hypertension should include drug classes demonstrated to reduce cardiovascular events in patients with diabetes (ACE inhibitors, angiotensin receptor blockers, thiazide-like diuretics, or dihydropyridine calcium channel blockers). ACE inhibitors or angiotensin receptor blockers are recommended first-line therapy for hypertension in people with diabetes and coronary artery disease.</li> <li>• Multiple-drug therapy is generally required to achieve blood pressure targets (but not a combination of ACE inhibitors and angiotensin receptor blockers).</li> <li>• An ACE inhibitor or angiotensin receptor blocker, at the maximum tolerated dose indicated for blood pressure treatment, is the recommended first-line treatment for hypertension in patients with diabetes and urinary albumin-to-creatinine ratio <math>\geq</math>300 mg/g creatinine or 30 to 299 mg/g creatinine. If one class is not tolerated, the other should be substituted.</li> <li>• For patients treated with an ACE inhibitor, angiotensin receptor blocker, or</li> </ul>

Clinical Guideline	Recommendations
	<p>diuretic, serum creatinine/estimated glomerular filtration rate and serum potassium levels should be monitored at least annually.</p> <ul style="list-style-type: none"> <li>• Patients with hypertension who are not meeting blood pressure targets on three classes of antihypertensive medications (including a diuretic) should be considered for mineralocorticoid receptor antagonist therapy.</li> </ul> <p><b>Chronic kidney disease</b></p> <ul style="list-style-type: none"> <li>• At least once a year, assess urinary albumin (e.g., spot urinary albumin-to-creatinine ratio) and estimated glomerular filtration rate in patients with type 1 diabetes with duration of five or more years and in all patients with type 2 diabetes.</li> <li>• Patients with diabetes and urinary albumin <math>\geq 300</math> mg/g creatinine and/ or an estimated glomerular filtration rate 30 to 60 mL/min/1.73 m<sup>2</sup> should be monitored twice annually to guide therapy.</li> <li>• Optimize glucose control to reduce the risk or slow the progression of chronic kidney disease (CKD).</li> <li>• For patients with type 2 diabetes and diabetic kidney disease, use of a sodium-glucose cotransporter 2 inhibitor in patients with an estimated glomerular filtration rate <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> and urinary albumin <math>\geq 300</math> mg/g creatinine is recommended to reduce CKD progression and cardiovascular events.</li> <li>• In patients with type 2 diabetes and CKD, consider use of sodium-glucose cotransporter 2 inhibitors additionally for cardiovascular risk reduction when estimated glomerular filtration rate and urinary albumin creatinine are <math>\geq 25</math> mL/min/1.73 m<sup>2</sup> or <math>\geq 300</math> mg/g, respectively.</li> <li>• In patients with CKD who are at increased risk for cardiovascular events or CKD progression and are unable to use a sodium-glucose cotransporter 2 inhibitor, a nonsteroidal mineralocorticoid receptor antagonist (finerenone) is recommended to reduce CKD progression and cardiovascular events.</li> <li>• Optimize blood pressure control and reduce blood pressure variability to reduce the risk or slow the progression of CKD.</li> <li>• Do not discontinue renin-angiotensin system blockade for minor increases in serum creatinine (<math>\leq 30\%</math>) in the absence of volume depletion.</li> <li>• For people with nondialysis-dependent stage 3 or higher CKD, dietary protein intake should be a maximum of 0.8 g/kg body weight per day (the recommended daily allowance). For patients on dialysis, higher levels of dietary protein intake should be considered, since malnutrition is a major problem in some dialysis patients.</li> <li>• In nonpregnant patients with diabetes and hypertension, either an ACE inhibitor or an angiotensin receptor blocker is recommended for those with modestly elevated urinary albumin-to-creatinine ratio (30 to 299 mg/g creatinine) and is strongly recommended for those with urinary albumin-to-creatinine ratio <math>\geq 300</math> mg/g creatinine and/or estimated glomerular filtration rate <math>&lt; 60</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Periodically monitor serum creatinine and potassium levels for the development of increased creatinine or changes in potassium when ACE inhibitors, angiotensin receptor blockers, or diuretics are used.</li> <li>• An ACE inhibitor or an angiotensin receptor blocker is not recommended for the primary prevention of CKD in patients with diabetes who have normal blood pressure, normal urinary albumin-to-creatinine ratio (<math>&lt; 30</math> mg/g creatinine), and normal estimated glomerular filtration rate.</li> <li>• Patients should be referred for evaluation by a nephrologist if they have an estimated glomerular filtration rate <math>&lt; 30</math> mL/min/1.73 m<sup>2</sup>.</li> <li>• Promptly refer to a nephrologist for uncertainty about the etiology of kidney disease, difficult management issues, and rapidly progressing kidney disease.</li> </ul>

\*Agent is not available in the United States.

### III. Indications

The Food and Drug Administration (FDA)-approved indications for the angiotensin-converting enzyme inhibitors are noted in Tables 3 and 4. While agents within this therapeutic class may have demonstrated positive activity via in vitro trials, the clinical significance of this activity remains unknown until fully demonstrated in well-controlled, peer-reviewed in vivo clinical trials. As such, this review and the recommendations provided are based exclusively upon the results of such clinical trials.

**Table 3. FDA-Approved Indications for the Angiotensin-Converting Enzyme Inhibitors<sup>3-18</sup>**

Indication(s)	Single Entity Agents									
	Benaze- pril	Capto- pril	Enala- pril	Fosino- pril	Lisino- pril	Moexi- pril	Perindo- pril	Quina- pril	Rami- pril	Trandola- pril
<b>Cardiovascular Risk Reduction</b>										
In patients 55 years or older at high risk of developing a major cardiovascular event because of a history of coronary artery disease, stroke, peripheral vascular disease, or diabetes that is accompanied by at least one other cardiovascular risk factor to reduce the risk of myocardial infarction, stroke, or death from cardiovascular causes									✓	
Stable coronary artery disease to reduce the risk of cardiovascular mortality or nonfatal myocardial infarction							✓			
<b>Diabetic Nephropathy</b>										
Treatment of diabetic nephropathy in patients with type 1 insulin-dependent diabetes and retinopathy		✓								
<b>Heart Failure</b>										
Congestive heart failure		✓ *	✓ *							
Heart failure				✓ †	✓ ‡			✓ †		
<b>Hypertension</b>										
Hypertension	✓ §	✓	✓	✓ §	✓	✓ §	✓	✓ §	✓ §	✓
<b>Left Ventricular Dysfunction</b>										
Decrease the rate of the development of overt heart failure and decrease the incidence of hospitalization for heart failure in clinically stable asymptomatic patients with left ventricular dysfunction (ejection fraction ≤35%)			✓							
<b>Myocardial Infarction</b>										
Hemodynamically stable patients within 24 hours of acute myocardial infarction to improve survival					✓					
Improve survival following myocardial infarction in clinically stable patients with left ventricular dysfunction manifested as an ejection fraction ≤40%		✓								

Indication(s)	Single Entity Agents									
	Benazepril	Captopril	Enalapril	Fosinopril	Lisinopril	Moexipril	Perindopril	Quinapril	Ramipril	Trandolapril
and to reduce the incidence of overt heart failure and subsequent hospitalizations for congestive heart failure in these patients										
Stable patients who have demonstrated clinical signs of congestive heart failure within the first few days after sustaining acute myocardial infarction									✓	
Stable patients who have evidence of left ventricular systolic dysfunction or who are symptomatic from congestive heart failure within the first few days after sustaining acute myocardial infarction										✓

\*Usually in combination with diuretics and digitalis.

† As adjunctive therapy when added to conventional therapy including diuretics with or without digitalis.

‡ As adjunctive therapy in patients who are not responding adequately to diuretics and digitalis.

§ May be used alone or in combination with thiazide diuretics.

|| May be used alone or in combination with other antihypertensive agents.

#### V. Drug Interactions

Major drug interactions with the angiotensin-converting enzyme inhibitors are listed in Table 6.

**Table 6. Major Drug Interactions with the Angiotensin-Converting Enzyme Inhibitors<sup>19</sup>**

<b>Generic Name(s)</b>	<b>Interaction</b>	<b>Mechanism</b>
ACE inhibitors (benazepril, captopril, enalapril, fosinopril, lisinopril, moexipril, perindopril, quinapril, ramipril,trandolapril)	Potassium-sparing diuretics	Combining ACE inhibitors and potassium-sparing diuretics may result in elevated serum potassium concentrations in certain high-risk patients.
ACE inhibitors (benazepril, captopril, enalapril, fosinopril, lisinopril, moexipril, perindopril, quinapril, ramipril,trandolapril)	Sacubitril	Concurrent use of sacubitril and ACE Inhibitors may result in Increased risk of angioedema.
ACE inhibitors (benazepril, captopril, enalapril, fosinopril, lisinopril, moexipril, perindopril, quinapril, ramipril,trandolapril)	Aliskiren	The risk of hyperkalemia may be increased when ACE inhibitors are combined with aliskiren.
ACE inhibitors (benazepril, captopril, enalapril, fosinopril, lisinopril, moexipril, perindopril, quinapril, ramipril,trandolapril)	Angiotensin II receptor antagonists	The risk of hyperkalemia may be increased when ACE inhibitors are combined with angiotensin II receptor antagonists.
ACE inhibitors (benazepril, captopril, enalapril, fosinopril, lisinopril, moexipril, perindopril, quinapril, ramipril,trandolapril)	Indomethacin	Indomethacin inhibits prostaglandin synthesis. The hypotensive effect of ACE inhibitors may be reduced.
ACE inhibitors (benazepril, captopril, enalapril, fosinopril, lisinopril, moexipril, perindopril, quinapril, ramipril,trandolapril)	NSAIDs and salicylates	NSAIDs and salicylates inhibit prostaglandin synthesis. The hypotensive and vasodilator effects of the ACE inhibitor may be reduced.
ACE inhibitors (benazepril, captopril, enalapril, fosinopril, lisinopril, moexipril, perindopril, quinapril, ramipril,trandolapril)	Potassium preparations	Hyperkalemia, possibly with cardiac arrhythmias or cardiac arrest, may occur with the combination of ACE inhibitors and potassium preparations.
ACE inhibitors (benazepril, captopril, enalapril, fosinopril, lisinopril, moexipril, perindopril, quinapril, ramipril,trandolapril)	Everolimus, sirolimus	Concurrent use of ACE inhibitors and MTOR inhibitors may result in increased risk of angioedema.
ACE inhibitors (benazepril, captopril, enalapril, fosinopril, lisinopril, moexipril, perindopril, quinapril, ramipril,trandolapril)	Trimethoprim	Hyperkalemia, possibly with cardiac arrhythmias or cardiac arrest, may occur with the combination of ACE inhibitors and trimethoprim.
ACE inhibitors	Lithium	Through an unknown mechanism, ACE inhibitors

Generic Name(s)	Interaction	Mechanism
(benazepril, captopril, enalapril, fosinopril, lisinopril, moexipril, quinapril, ramipril, trandolapril)		may increase lithium levels, which results in neurotoxicity.
Thiazide diuretics (HCTZ)	Dofetilide	Thiazide diuretics increase potassium excretion. Hypokalemia may occur, increasing the risk of torsades de pointes.
Thiazide diuretics (HCTZ)	Lithium	Thiazide diuretics decrease the renal clearance of lithium which leads to increased serum lithium levels. Lithium toxicity has occurred.
Thiazide diuretics (HCTZ)	Diazoxide	Hyperglycemia may occur with symptoms similar to diabetes. The mechanism is unknown.
Thiazide diuretics (HCTZ)	Digitalis glycosides	Diuretic-induced electrolyte disturbances may predispose the patient to digitalis-induced cardiac arrhythmias.

ACE inhibitor=angiotensin converting enzyme inhibitor, HCTZ=hydrochlorothiazide, HMG CoA=3-hydroxy-3-methyl-glutaryl-CoA, NSAID=nonsteroidal anti-inflammatory drug

## VI. Adverse Drug Events

The most common adverse drug events reported with the angiotensin-converting enzyme inhibitors are listed in Tables 7 and 8. The boxed warning for the angiotensin-converting enzyme inhibitors is listed in Table 9.

**Table 7. Adverse Drug Events (%) Reported with the Angiotensin-Converting Enzyme Inhibitors-Single Entity Agents<sup>3-19</sup>**

**Table 9. Boxed Warning for the Angiotensin-Converting Enzyme Inhibitors<sup>18</sup>**

<b>WARNING</b>
When pregnancy is detected, discontinue therapy as soon as possible. Drugs that act directly on the renin-angiotensin system can cause injury and death to the developing fetus.

## VII. Dosing and Administration

The usual dosing regimens for the angiotensin-converting enzyme inhibitors are listed in Table 10.

**Table 10. Usual Dosing Regimens for the Angiotensin-Converting Enzyme Inhibitors<sup>3-19</sup>**

<b>Generic Name(s)</b>	<b>Usual Adult Dose</b>	<b>Usual Pediatric Dose</b>	<b>Availability</b>
<b>Single Entity Agents</b>			
Benazepril	<u>Hypertension:</u> Tablet: initial, 5 to 10 mg once daily (for patients not receiving diuretics); maintenance, 20 to 40 mg/day as a single dose or in two equally divided doses; maximum, >80 mg/day has not been evaluated	<u>Hypertension for children ≥6 years of age:</u> Tablet: initial, 0.2 mg/kg once daily; maximum, >0.6 mg/kg (or in excess of 40 mg daily) has not been studied  Safety and efficacy in children <6 years of age have not been established.	Tablet: 5 mg 10 mg 20 mg 40 mg
Captopril	<u>Diabetic nephropathy:</u> Tablet: maintenance, 25 mg three times daily  <u>Heart failure:</u> Tablet: initial, 25 mg three times daily; maximum, 450 mg/day  <u>Hypertension:</u> Tablet: initial, 25 mg two to three times daily; maintenance, after one to two weeks can increase to 50 mg two to three times daily; maximum: 450 mg/day  <u>Myocardial infarction (left ventricular dysfunction after myocardial infarction):</u> Tablet: initial, 6.25 mg once, followed by 12.5 mg three times daily; target maintenance, 50 mg three times daily	Safety and efficacy in children have not been established.	Tablet: 12.5 mg 25 mg 50 mg 100 mg
Enalapril	<u>Heart failure:</u> Solution, tablet: initial, 2.5 mg/day; maintenance, 2.5 to 20 mg two times daily; maximum, 40 mg/day in divided doses  <u>Hypertension:</u> Solution, tablet: initial, 5 mg once daily; maintenance, 10 to 40 mg/day as a single dose or in two divided doses	<u>Hypertension in children 1 month to 16 years of age:</u> Solution, tablet: initial, 0.08 mg/kg (up to 5 mg) once daily; maximum, >0.58 mg/kg (or in excess of 40 mg) has not been studied  Safety and efficacy in children <1 month have not been established.	Solution: 1 mg/mL  Tablet: 2.5 mg 5 mg 10 mg 20 mg

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
	<u>Left ventricular dysfunction:</u> Solution ,tablet: initial, 2.5 mg two times daily; target maintenance, 10 mg/day in divided doses		
Fosinopril	<u>Heart failure:</u> Tablet: initial, 10 mg once daily; maintenance, 20 to 40 mg/day; maximum, 40 mg once daily  <u>Hypertension:</u> Tablet: initial, 10 mg once daily; maintenance, 20 to 40 mg/day in a single or divided dose(s); maximum, 80 mg/day	<u>Hypertension in children 6 to 16 years of age:</u> Tablet (>50 kg): 5 to 10 mg once daily  Safety and efficacy in children <6 years of age have not been established.	Tablet: 10 mg 20 mg 40 mg
Lisinopril	<u>Heart failure:</u> Solution, tablet: initial, 5 mg once daily; maintenance, 5 to 20 mg once daily  <u>Hypertension:</u> Solution, tablet: initial, 10 mg once daily; maintenance, 20 to 40 mg once daily  <u>Post-myocardial infarction:</u> Solution, tablet: initial, 5 mg every 24 hours for two doses, followed by 10 mg every day for 6 weeks	<u>Hypertension in children 6 to 16 years of age:</u> Solution, tablet: initial, 0.07 mg/kg (up to 5 mg) once daily; doses >0.6 mg/kg (or in excess of 40 mg) have not been studied  Safety and efficacy in children <6 years of age have not been established.	Solution: 1 mg/ mL  Tablet: 2.5 mg 5 mg 10 mg 20 mg 30 mg 40 mg
Moexipril	<u>Hypertension:</u> Tablet: initial, 7.5 mg once daily; maintenance, 7.5 to 30 mg/day in a single or divided dose(s); maximum, 60 mg/day	Safety and efficacy in children have not been established.	Tablet: 7.5 mg 15 mg
Perindopril	<u>Cardiovascular risk reduction (coronary artery disease):</u> Tablet: initial: 4 mg once daily for 2 weeks; maintenance, increase as tolerated to 8 mg once daily  <u>Hypertension:</u> Tablet: initial, 4 mg once daily; maintenance, 4 to 8 mg/day in a single or divided dose(s); maximum, 16 mg/day	Safety and efficacy in children have not been established.	Tablet: 2 mg 4 mg 8 mg
Quinapril	<u>Heart failure:</u> Tablet: initial, 5 mg twice daily; maintenance, titrate at weekly intervals to 10 to 20 mg two times daily  <u>Hypertension:</u> Tablet: initial, 10 to 20 mg once daily; maintenance, 20 to 80 mg/day in a single or divided dose(s)	Safety and efficacy in children have not been established.	Tablet: 5 mg 10 mg 20 mg 40 mg
Ramipril	<u>Cardiovascular risk reduction:</u>	Safety and efficacy in	Capsule:

Generic Name(s)	Usual Adult Dose	Usual Pediatric Dose	Availability
	<p>Capsule: initial, 2.5 mg once daily for one week, followed by 5 mg once daily for three weeks; maintenance, 10 mg once daily</p> <p><u>Hypertension:</u> Capsule: initial, 2.5 mg once daily; maintenance, 2.5 to 20 mg/day in single or divided dose(s)</p> <p><u>Post-myocardial infarction (heart failure after myocardial infarction):</u> Capsule: initial, 2.5 mg twice daily; target maintenance, 5 mg twice daily</p>	children have not been established.	1.25 mg 2.5 mg 5 mg 10 mg
Trandolapril	<p><u>Post-myocardial infarction (left ventricular dysfunction or heart failure after myocardial infarction):</u> Tablet: initial, 1 mg once daily; maintenance, titrate as tolerated to target of 4 mg once daily</p> <p><u>Hypertension:</u> Tablet: initial, 1 mg once daily in non-African American patients and 2 mg once daily in African American patients; maintenance, 2 to 4 mg once daily</p>	Safety and efficacy in children have not been established.	Tablet: 1 mg 2 mg 4 mg
<b>Combination Products</b>			
Benazepril and HCTZ	<p><u>Hypertension:</u> Tablet: initial, 10-12.5 or 20-12.5 mg/day if not adequately controlled on benazepril monotherapy; maintenance, titrate dose by clinical effect</p>	Safety and efficacy in children have not been established.	Tablet: 5-6.25 mg 10-12.5 mg 20-12.5 mg 20-25 mg
Captopril and HCTZ	<p><u>Hypertension:</u> Tablet: initial, 25-5 mg once daily; titrate dose by clinical effect; maximum, 150-50 mg/day</p>	Safety and efficacy in children have not been established.	Tablet: 25-15 mg 25-25 mg 50-15 mg 50-25 mg
Enalapril and HCTZ	<p><u>Hypertension:</u> Tablet: maximum, four tablets of 5-12.5 mg or two tablets of 10-25 mg</p>	Safety and efficacy in children have not been established.	Tablet: 5-12.5 mg 10-25 mg
Fosinopril and HCTZ	<p><u>Hypertension:</u> Tablet: titrate dose by clinical effect</p>	Safety and efficacy in children have not been established.	Tablet: 10-12.5 mg 20-12.5 mg
Lisinopril and HCTZ	<p><u>Hypertension:</u> Tablet: initial, 10-12.5 or 20-12.5 mg/day after failure on monotherapy; titrate dose by clinical effect; maximum, 80-50 mg/day</p>	Safety and efficacy in children have not been established.	Tablet: 10-12.5 mg 20-12.5 mg 20-25 mg
Quinapril and HCTZ	<p><u>Hypertension:</u> Tablet: initial, 10-12.5 or 20-12.5 mg/day; maintenance, titrate dose by clinical effect</p>	Safety and efficacy in children have not been established.	Tablet: 10-12.5 mg 20-12.5 mg 20-25 mg

HCTZ=hydrochlorothiazide

**VIII. Effectiveness**

Clinical studies evaluating the safety and efficacy of the angiotensin-converting enzyme inhibitors are summarized in Table 11.

**Table 11. Comparative Clinical Trials with the Angiotensin-Converting Enzyme Inhibitors**

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<b>Cardiovascular Disease</b>				
<p>Jamerson et al.<sup>39</sup> (2008) ACCOMPLISH</p> <p>Benazepril 20 to 40 mg QD and HCTZ 12.5 to 25 mg QD</p> <p>vs</p> <p>benazepril 20 to 40 mg QD and amlodipine 5 to 10 mg QD</p>	<p>AC, DB, MC, RCT</p> <p>Patients &gt;60 years of age with HTN and at high risk of cardiovascular events</p>	<p>N=11,506</p> <p>36 months (mean)</p>	<p>Primary: The composite of death from cardiovascular causes, nonfatal MI, nonfatal stroke, hospitalization for angina, resuscitation after sudden cardiac arrest, and coronary revascularization.</p> <p>Secondary: Death from cardiovascular causes, nonfatal MI, and nonfatal stroke</p>	<p>Primary: There were 552 primary-outcome events in the benazepril plus amlodipine group (9.6%) and 679 events in the benazepril plus HCTZ group (11.8%). The absolute risk reduction with benazepril plus amlodipine therapy was 2.2% and the relative risk reduction was 19.6% compared to benazepril plus HCTZ (HR, 0.80; 95% CI, 0.72 to 0.90; P&lt;0.001).</p> <p>Secondary: For the secondary end point of death from cardiovascular causes, nonfatal MI, and nonfatal stroke, there were 288 (5%) events in the benazepril plus amlodipine group compared to 364 (6.3%) events in the benazepril plus HCTZ group. The absolute risk reduction with benazepril plus amlodipine therapy was 1.3% and the RR reduction was 21.2% compared to benazepril plus HCTZ (HR, 0.79; 95% CI, 0.67 to 0.92; P=0.002).</p>
<p>Weber et al.<sup>40</sup> (2010) ACCOMPLISH</p> <p>Benazepril and amlodipine 40-5 to 40-10 mg/day, followed by forced titration after 1 month on</p>	<p>Prespecified subanalysis of ACCOMPISH</p> <p>Men and women &gt;60 years of age with HTN and at high risk for cardiovascular events (history of</p>	<p>N=6,946</p> <p>Mean treatment duration 29.7 months for benazepril and amlodipine group and 29.5 months for</p>	<p>Primary: Primary: Time to first event (composite of cardiovascular event and death from cardiovascular causes)</p>	<p>Primary: The primary endpoint occurred in 8.8% of diabetic patients in the benazepril and amlodipine group and 11.0% in the benazepril and HCTZ group (HR, 0.79; P=0.003; NNT, 46). In high risk diabetic patients, 13.6% of patients in the benazepril and amlodipine group and 17.3% in the benazepril and HCTZ group (HR, 0.77, P=0.007; NNT, 28).</p> <p>Secondary: Due to early termination, the study had limited power to detect differences in the diabetic subgroups.</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>benazepril and amlodipine 20-5 mg (fixed-dose combination product)</p> <p>vs</p> <p>benazepril and HCTZ 40-12.5 to 40-25 mg/day, followed by forced titration after one month on benazepril and HCTZ 20-12.5 mg (fixed-dose combination product)</p>	<p>coronary events, MI, revascularization, or stroke; impaired renal function; peripheral arterial disease, left ventricular hypertrophy; or diabetes)</p> <p>(Subanalysis of patients with diabetes)</p>	<p>benazepril and HCTZ group</p>	<p>Secondary: Composite of cardiovascular events (the primary endpoint excluding fatal events) and composite of death from cardiovascular disease, nonfatal stroke and nonfatal MI</p>	<p>Peripheral edema was higher in the benazepril and amlodipine group compared to the benazepril and HCTZ group.</p>
<p>Weber et al.<sup>41</sup> (2013) ACCOMPLISH</p> <p>Benazepril and amlodipine 40-5 to 40-10 mg/day, followed by forced titration after 1 month on benazepril and amlodipine 20-5 mg (fixed-dose combination product)</p> <p>vs</p>	<p>Subanalysis of ACCOMPLISH based on body size</p> <p>Patients &gt;60 years of age with HTN and at high risk of cardiovascular events</p>	<p>N=11,482</p> <p>Duration not specified</p>	<p>Primary: Composite of cardiovascular death or nonfatal MI or stroke</p> <p>Secondary: Cardiovascular death, total MI, total stroke</p>	<p>Primary: In patients receiving benazepril and HCTZ, the primary endpoint (per 1,000 patient-years) was 30.7 in normal weight (BMI &lt;25), 21.9 in overweight (BMI ≥25 to &lt;30), and 18.2 in obese patients (BMI ≥30) (overall P=0.0034). In patients receiving benazepril and amlodipine, the primary endpoint did not differ between the three BMI groups (18.2, 16.9, and 16.5, respectively; P=0.9721). In obese patients, primary event rates were similar between the two treatments, but rates were significantly lower with benazepril and amlodipine in overweight patients (HR, 0.76; 95% CI, 0.59 to 0.94; P=0.0369) and normal weight patients (HR, 0.57; 95% CI, 0.39 to 0.84; P=0.0037).</p> <p>Secondary: Comparing obese and overweight patients, event rates were all numerically lower, but not significantly lower, in obese patients. Cardiovascular deaths were significantly lower in overweight patients compared to normal weight patients (HR, 0.57; 95% CI, 0.37 to 0.89; P=0.0125). Cardiovascular death (HR, 0.40; 95% CI, 0.25 to 0.63;</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
benazepril and HCTZ 40-12.5 to 40-25 mg/day, followed by forced titration after 1 month on benazepril and HCTZ 20-12.5 mg (fixed-dose combination product)				P<0.0001) and total stroke (HR, 0.60; 95% CI, 0.37 to 0.96; P=0.0335) were significantly lower in obese patients compared to normal weight patients.
Swedberg et al. <sup>42</sup> (1992) CONSENSUS II  Enalapril 5 to 20 mg/day  vs  placebo  Treatment was started with an IV infusion of 1 mg of enalaprilat administered over 3 hours followed by oral enalapril 6 hours after the infusion was stopped.	DB, MC, PC, PG, RCT  Patients who presented within 24 hours of the onset of acute MI symptoms	N=6,090  180 days	Primary: Mortality rates within 6 months  Secondary: Mortality within 1 month, cause of death, re-infarction, or worsening heart failure	Primary: Mortality rates according to life-table analysis between the enalapril and placebo groups at six months were not significantly different (11 vs 10.2%; P=0.26). The RR associated with enalapril treatment and based on the mortality curves was 1.10 (95% CI, 0.93 to 1.29).  Secondary: Mortality rates between the enalapril and placebo groups at one month were not significantly different (7.2 vs 6.3%; P=0.26).  Death due to progressive heart failure occurred more frequently in patients treated with enalapril than placebo (4.3 vs 3.4%; P=0.06).  There were no significant differences in the rate of reinfarction between the enalapril or placebo groups (P value not significant).  Change in therapy because of heart failure occurred more in the placebo group (P<0.006) but there were no significant differences in hospitalization for heart failure (P value not significant).  Note: The first CONSENSUS trial excluded patients with a recent MI or unstable angina. The study was stopped early after recruiting 6,090 of the intended 9,000 patients since more patients had died on the drug than on placebo (although the difference was not statistically significant).
Wing et al. <sup>43</sup> (2003)	MC, OL, PRO, RCT	N=6,083	Primary: All cardiovascular	Primary: By the end of the study, blood pressure had decreased to a similar extent in

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
<p>ANBP2</p> <p>Enalapril</p> <p>vs</p> <p>HCTZ</p> <p>The choice of the specific agent and dose was made by the family practitioner.</p>	<p>Patients 65 to 84 years of age with average SBP while sitting of <math>\geq 160</math> mm Hg or an average DBP of <math>\geq 90</math> mm Hg (if the SBP was <math>\geq 140</math> mm Hg)</p>	<p>4.1 years (median)</p>	<p>events or death from any cause (both initial and subsequent fatal and nonfatal cardiovascular events)</p> <p>Secondary: Not reported</p>	<p>both groups (a decrease of 26/12 mm Hg).</p> <p>There were 695 cardiovascular events or deaths from any cause in the ACE inhibitor group (56.1 per 1,000 patient-years; HR, 0.89; 95% CI, 0.79 to 1.0; P=0.05) compared to 736 in the diuretic group (59.8 per 1,000 patient-years).</p> <p>The beneficial effects of ACE inhibitor treatment were more evident in male subjects (HR, 0.83; 95% CI, 0.71 to 0.97; P=0.02).</p> <p>The rates of nonfatal cardiovascular events and MI decreased with ACE inhibitor treatment, whereas a similar number of strokes occurred in each group (although there were more fatal strokes in the ACE inhibitor group).</p> <p>Secondary: Not reported</p>
<p>Nissen et al.<sup>44</sup> (2004)</p> <p>CAMELOT</p> <p>Enalapril 10 to 20 mg/day</p> <p>vs</p> <p>amlodipine 5 to 10 mg/day</p> <p>vs</p> <p>placebo</p>	<p>DB, MC, PC, RCT</p> <p>Patients 30 to 79 years of age requiring coronary angiography for evaluation for chest pain or PCI and a diastolic pressure <math>&lt; 100</math> mm Hg, with or without treatment</p>	<p>N=1,991</p> <p>2 years</p>	<p>Primary: Composite of cardiovascular events (cardiovascular death, nonfatal MI, resuscitated cardiac arrest, coronary revascularization, hospitalization for angina pectoris, hospitalization for CHF, fatal or nonfatal stroke or TIA, and any new diagnosis of PVD), nominal change in percent atheroma volume (substudy)</p>	<p>Primary: Cardiovascular events occurred in 23.1% of placebo-treated patients, 16.6% amlodipine-treated patients (HR, 0.69; 95% CI, 0.54 to 0.88; P=0.003) and 20.2% enalapril-treated patients (HR, 0.85; 95% CI, 0.67 to 1.17; P=0.16).</p> <p>The primary end point comparison for enalapril vs amlodipine was not significant (HR, 0.81; 95% CI, 0.63 to 1.04; P=0.10).</p> <p>Secondary: Coronary revascularization was reduced in the amlodipine group from 15.7 to 11.8% (HR, 0.73; 95% CI, 0.54 to 0.98; P=0.03). Hospitalization for angina was reduced in the amlodipine group from 12.8 to 7.7% (HR, 0.58; 95% CI, 0.41 to 0.82; P=0.002).</p> <p>Individual components of the primary end point generally showed fewer events with enalapril treatment vs placebo, but none of the comparisons reached statistical significance.</p> <p>For components of the primary end point, only the rate of hospitalization for angina showed a statistically significant difference between amlodipine</p>

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
			<p>Secondary: Incidence of adverse events; all-cause mortality, incidence of revascularization in vessels that had undergone previous stent placement</p>	<p>and enalapril (HR, 0.59; 95% CI, 0.42 to 0.84; P=0.003). A trend toward fewer episodes of revascularization in patients undergoing intervention at baseline was observed for amlodipine vs enalapril (HR, 0.66; 95% CI, 0.40 to 16; P=0.09).</p> <p>The mean change in percent atheroma volume was 0.5% for amlodipine (P=0.12 vs placebo), 0.8% for enalapril (P=0.32 vs placebo) and 1.3% for placebo. In patients with SBP greater than the mean, the amlodipine group showed a significantly slower progression (0.2%) compared to placebo (2.3%; P=0.02). Compared to baseline, intravascular ultrasound showed progression in patients receiving placebo (P&lt;0.001), a trend toward progression with enalapril (P=0.08) and no progression in patients receiving amlodipine (P=0.31). For the amlodipine group, correlation between blood pressure reduction and progression was r=0.19 (P=0.07).</p> <p>Discontinuation from the study for treatment-emergent adverse events was low, averaging 0.4% and not statistically significant between the three treatment groups.</p> <p>The only statistically significant difference in secondary end points was that amlodipine demonstrated a significant reduction in revascularization after previous stent placement compared to placebo (4.1 vs 7.9%; HR, 0.49; 95% CI, 0.31 to 0.78; P=0.002). The rate of revascularization was lower than enalapril (6.2%) but not statistically significant (HR 0.66, 95% CI, 0.40 to 16; P=0.09).</p>
<p>Pitt et al.<sup>45</sup> (2003) 4E-Left Ventricular Hypertrophy Study  Enalapril 40 mg QD  vs</p>	<p>AC, DB, PG, RCT  Patients with left ventricular hypertrophy, a history of HTN and predominantly in sinus rhythm</p>	<p>N=153  9 months</p>	<p>Primary: Change in left ventricular mass as assessed by MRI</p> <p>Secondary: Reduction in SBP and DBP, response rate (DBP &lt;90 mm Hg), change in urine albumin creatinine ratio</p>	<p>Primary: Both treatments were associated with a significant reduction in left ventricular mass from baseline (P&lt;0.001). The difference in left ventricular mass reduction from baseline between the two treatments was not significant (P=0.258).</p> <p>While enalapril plus eplerenone therapy demonstrated a significantly greater reduction in left ventricular mass from baseline compared to eplerenone therapy (P=0.007); the effect was not statistically different from that observed with enalapril therapy (P=0.107).</p> <p>Secondary:</p>

(2004) PEACE  Trandolapril 4 mg/day  vs  placebo	Patients $\geq 50$ years of age with stable CAD and normal or slightly reduced left ventricular function (LVEF $>40\%$ )	4.8 years (median)	nonfatal MI, death from cardiovascular causes, or coronary revascularization procedures  Secondary: Composite of death from cardiovascular causes, nonfatal MI, revascularization, unstable angina, new CHF, stroke, PVD, and cardiac arrhythmia	trandolapril and placebo were reported (21.9 vs 22.5%; HR, 0.96; 95% CI, 0.88 to 1.6; P=0.43).  Secondary: No significant differences in secondary outcome measures between trandolapril and placebo were reported (P $>0.05$ ).  Side effects leading to discontinuation of study medication occurred in 14.4% of patients receiving trandolapril and 6.5% of patients receiving placebo (P $<0.001$ ). The rates of cough (39.1 vs 27.5%; P $<0.01$ ) and syncope (4.8 vs 3.9%; P=0.04) were higher in patients receiving trandolapril vs placebo.  Note: This trial was conducted in low-risk patients with stable CAD and normal or slightly reduced left ventricular function. However, the HOPE trial was conducted in patients with coronary or other vascular disease or with diabetes and another cardiovascular risk factor and the EUROPA trial was conducted in patients with evidence of CHD.
Pilote et al. <sup>60</sup> (2004)  Captopril (50 mg), enalapril (10 mg), fosinopril (10 mg), lisinopril (10 mg), perindopril (4 mg), quinapril (20 mg), and ramipril (5 mg)	RETRO  Patients $\geq 65$ years who were hospitalized for acute myocardial infarction and filled a prescription for an ACE inhibitor within 30 days of discharge and who continued to receive the same drug for $\geq 1$ year	N=7,512  Average of 2.3 years since discharge	Primary: 1-year mortality following an acute MI  Secondary: Readmissions due to cardiac complications	Primary: Captopril (HR, 1.56; 95% CI, 1.13 to 2.15), enalapril (HR, 1.47; 95% CI, 1.14 to 1.89), fosinopril (HR, 1.71; 95% CI, 1.29 to 2.25), lisinopril (HR, 1.28; 95% CI, 0.98 to 1.67), and quinapril (HR, 1.58; 95% CI, 1.10 to 2.82) were associated with higher mortality than was ramipril.  No statistically significant difference was reported between perindopril and ramipril (HR, 0.98; 95% CI, 0.60 to 1.60).  Secondary: Enalapril (HR, 1.44; 95% CI, 1.13 to 2.01) and fosinopril (HR, 1.83; 95% CI, 1.27 to 2.62) were associated with higher readmission rates for CHF than ramipril. Readmissions for unstable angina and recurrent MI were similar across all prescription groups.
Dalhof et al. <sup>61</sup> (2005) ASCOT-BPLA  Amlodipine 5 to	MC, OL, RCT  Patients 40 to 79 years of age with HTN and $\geq 3$ other	N=19,257  5.5 years	Primary: Nonfatal MI (including silent MI) and fatal CHD	Primary: No statistically significant difference in nonfatal MI and fatal CHD was reported between the amlodipine plus perindopril group compared to the atenolol plus bendroflumethiazide groups (HR, 0.90; 95% CI, 0.79 to 1.2; P=0.1052).

placebo	LVEF $\leq$ 40%, but without overt heart failure or symptoms of myocardial ischemia		ejection fraction $\geq$ 9 units, cardiovascular morbidity, combination of cardiovascular mortality and morbidity  Secondary: Not reported	The incidence of nonfatal major cardiovascular events was consistently reduced in the captopril group with a 25% reduced risk of recurrent MI (P=0.015), 37% reduced risk for the development of severe heart failure (P<0.001), and 22% reduced risk of CHF requiring hospitalization (P=0.019).  Long-term captopril administration was associated with an improvement in survival and reduced morbidity and mortality due to major cardiovascular events.  Secondary: Not reported
Pitt et al. <sup>70</sup> (1997) ELITE  Captopril 50 mg TID  vs  losartan 50 mg QD	DB, MC, PG, RCT  Patients $\geq$ 65 years with symptomatic heart failure (NYHA class II to IV and LVEF $\leq$ 40%), and no history of prior ACE inhibitor therapy	N=722  1 year	Primary: Change in renal function  Secondary: Composite of death and/or hospital admission for heart failure, all-cause mortality, admission for heart failure, NYHA class, admission for MI or unstable angina	Primary: No difference between losartan and captopril was reported in the rate of persistent rise in serum creatinine concentrations (10.5% for both groups).  Secondary: Death and/or hospital admission for heart failure was recorded in 9.4% of patients receiving losartan and 13.2% for patients receiving captopril (risk reduction, 32%; 95% CI, -4 to 55; P=0.075). This risk reduction was primarily due to a decrease in all-cause mortality (4.8 vs 8.7%; risk reduction, 46%; 95% CI, 5 to 69; P=0.035).  Admissions with heart failure were the same in both groups (5.7%), as was improvement in NYHA functional class from baseline. Admission to hospital for any reason was less frequent with losartan than with captopril treatment (22.2 vs 29.7%; P=0.014).  More patients discontinued therapy due to adverse events with captopril (20.8%) than losartan (12.2%; P=0.002).
Pitt et al. <sup>71</sup> (2000) ELITE II  Captopril 50 mg TID	DB, MC, PG, RCT  Patients $\geq$ 60 years old with symptomatic heart failure (NYHA II to	N=3,152  555 days (mean follow-up)	Primary: All-cause mortality  Secondary: Composite of sudden cardiac	Primary: No significant difference in all-cause mortality was reported between losartan (17.7%) and captopril (15.9%; HR, 1.13; 95% CI, 0.95 to 1.35; P=0.16).  Secondary:

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs losartan 50 mg QD	IV and LVEF ≤40%), and no history of prior ACE inhibitor therapy		death or resuscitated cardiac arrest	Sudden death or resuscitated cardiac arrest was observed in 9.0% of patients receiving losartan and 7.3% of patients receiving captopril (HR, 1.25; 95% CI; 0.98 to 1.60; P=0.08).  Significantly fewer patients in the losartan group (excluding those who died) discontinued study treatment because of adverse events (9.7 vs 14.7%; P<0.001), including cough (0.3 vs 2.7%).  Note: ELITE II trial was a larger follow-up trial to the ELITE I trial to confirm the secondary end point from the ELITE I trial, which reported a greater reduction in all-cause mortality with losartan compared to captopril.
Dickstein et al. <sup>72</sup> (2002) OPTIMAAL  Captopril 50 mg TID  vs losartan 50 mg QD	DB, MC, PG, RCT  Patients ≥50 years with an acute MI and signs or symptoms of heart failure during the acute phase or a new Q-wave anterior infarction or reinfarction	N=5,477  2.7 years (mean)	Primary: All-cause mortality  Secondary: Composite of sudden cardiac death or resuscitated cardiac arrest	Primary: No significant difference in all-cause mortality was reported between patients receiving losartan and captopril (18 vs 16%, respectively; RR, 1.13; 95% CI, 0.99 to 1.28; P=0.07).  Secondary: No significant difference in sudden cardiac death or resuscitated cardiac arrest was reported between patients receiving losartan and captopril (9% vs 7%; RR, 1.19; 95% CI, 0.98 to 1.43; P=0.07).  Losartan was significantly better tolerated than captopril, with fewer patients discontinuing study medication (17 vs 23%; P<0.0001).
Pfeffer et al. <sup>73</sup> (2003) VALIANT  Captopril 50 mg TID  vs valsartan 160 mg BID  vs	DB, MC, RCT  Patients ≥18 years of age with an acute MI that was complicated by clinical or radiologic signs of heart failure and/or evidence of left ventricular systolic dysfunction	N=14,703  24.7 months	Primary: All-cause mortality  Secondary: Death from cardiovascular causes, recurrent MI, hospitalization for heart failure	Primary: No significant difference in all-cause mortality was reported between valsartan monotherapy and captopril monotherapy (P=0.98).  No significant difference in all-cause mortality was observed between valsartan plus captopril combination therapy and captopril monotherapy (P=0.73).  Secondary: The rate of death from cardiovascular causes, reinfarction, or hospitalization for heart failure was not significantly different between valsartan and captopril monotherapy (P=0.20).

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
valsartan 80 mg BID and captopril 50 mg TID				<p>The rate of death from cardiovascular causes, reinfarction, or hospitalization for heart failure was not significantly different between valsartan and captopril combination therapy and captopril monotherapy (P=0.37).</p> <p>Combination therapy had the most drug-related adverse events. With monotherapy, hypotension and renal dysfunction were more common in the valsartan group and cough, rash, and taste disturbance were more common in the captopril group.</p>
<p>CONSENSUS Trial Study Group<sup>74</sup> (1987) CONSENSUS Enalapril 2.5 to 40 mg/day vs placebo</p>	<p>DB, MC, PC, PG, RCT  Patients with severe CHF (NYHA class IV symptoms), patients with recent MI and unstable angina were excluded</p>	<p>N=253  188 days (average)</p>	<p>Primary: 6-month mortality and the cause of death  Secondary: 12-month mortality and overall mortality</p>	<p>Primary: Mortality at six months was 26 and 44% for patients in the enalapril and placebo groups, respectively, for an overall reduction of 40% for enalapril (P=0.002).</p> <p>Secondary: At 12 months, enalapril reduced mortality by 31% compared to placebo (P=0.001).</p> <p>By the end of the study, there had been 50 deaths in the enalapril group and 68 deaths in the placebo group for a reduction of 27% (P=0.003). The entire reduction in total mortality was found to be among patients with progressive heart failure (a reduction of 50%), whereas no difference was seen in the incidence of sudden cardiac death.</p> <p>Note: The study was stopped early due to clear benefit with enalapril.</p>
<p>SOLVD Investigators<sup>75</sup> (1991) SOLVD Enalapril 2.5 to 20 mg/day vs placebo</p>	<p>DB, MC, PC, RCT  Patients with CHF and LVEF ≤35% receiving conventional therapy</p>	<p>N=2,569  41.4 months (average)</p>	<p>Primary: Mortality, rate of hospitalization for heart failure  Secondary: Not reported</p>	<p>Primary: Death was reported in 35.2 and 39.7% of patients receiving enalapril and placebo, respectively (risk reduction, 16%; 95% CI, 5 to 26; P=0.0036).</p> <p>Although reductions in mortality were observed in several categories of cardiac deaths, the largest reduction occurred among the deaths attributed to progressive heart failure (risk reduction, 22%; 95% CI, 6 to 35). There was little apparent effect of treatment on deaths classified as due to arrhythmia without pump failure.</p> <p>Fewer patients died or were hospitalized for worsening heart failure (risk reduction, 26%; 95% CI, 18 to 34; P&lt;0.0001).</p>

				Secondary: Not reported
SOLVD Investigators <sup>76</sup> (1992) SOLVD  Enalapril 2.5 mg to 20 mg/day  vs  placebo	DB, MC, PC, RCT  Patients 21 to 80 years of age with heart disease and an ejection fraction of ≤35% who were not receiving diuretics, digoxin or vasodilators for the treatment of heart failure	N=4,228  37.4 months (average)	Primary: All-cause mortality, incidence of heart failure, rate of hospitalization for heart failure  Secondary: Not reported	Primary: Enalapril resulted in an 8% reduction in risk for all-cause mortality (P=0.30). The difference was entirely due to a reduction in deaths due to cardiovascular causes, primarily progressive heart failure (risk reduction, 12%; P=0.12).  In the placebo group, 30.2% of patients developed heart failure compared to 20.7% for enalapril (risk reduction, 37%; P<0.001).  Rates of first hospitalization and multiple hospitalizations for CHF were higher with placebo (12.9 and 4.8%) than enalapril (8.7 and 2.7%; both P<0.001).  The total number of deaths and cases of heart failure were lower in the enalapril group than in the placebo group (risk reduction, 29%; P<0.001). In addition, fewer patients given enalapril died or were hospitalized for heart failure (risk reduction, 20%; P<0.001).  Secondary: Not reported
McMurray et al. <sup>77</sup> (2016) ATMOSPHERE  Enalapril 5 or 10 mg BID  vs  aliskiren 150 mg QD  vs	DB, DD, RCT  Patients with CHF (NYHA class II to IV) and EF ≤35% receiving stable doses of an ACE inhibitor (equivalent to at least 10 mg of enalapril daily) and of a β-blocker at the time of enrollment	N=7,016  Median of 36.6 months	Primary: Composite of death from cardiovascular causes or hospitalization for heart failure  Secondary: Change from baseline to 12 months in the Kansas City Cardiomyopathy	Primary: Overall, the primary outcome occurred in 770 patients (32.9%) in the combination-therapy group (11.7 events per 100 person-years), in 791 patients (33.8%) in the aliskiren group (12.1 events per 100 person-years), and in 808 patients (34.6%) in the enalapril group (12.4 events per 100 person-years). The HR in the combination-therapy group, as compared with the enalapril group, was 0.93 (95% CI, 0.85 to 1.03; P=0.17); the HR in the aliskiren group, as compared with the enalapril group, was 0.99 (95% CI, 0.90 to 1.10; P=0.91 for superiority). Although the noninferiority margin of 1.104 was met with the use of the 95% confidence interval, the one-sided P value of 0.0184 did not fulfill the prespecified requirement of a P value of 0.0123 or less. A sensitivity analysis that included only patients who received the assigned trial regimen gave consistent results, as did an analysis in which data that were collected after regulatory censoring

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
combination of aliskiren 150 mg QD and enalapril 5 or 10 mg BID			Questionnaire (KCCQ) clinical summary score	<p>were included.</p> <p>Secondary: There were no significant between-group differences in the secondary outcome. The exploratory composite renal outcome (the composite of death from renal causes, end-stage renal disease, or doubling of the serum creatinine level) occurred significantly more frequently in the combination-therapy group than in the enalapril group.</p>
<p>McKelvie et al.<sup>78</sup> (1999) RESOLVD</p> <p>Enalapril 10 mg BID</p> <p>vs</p> <p>candesartan 4 to 16 mg QD</p> <p>vs</p> <p>candesartan 4 to 8 mg QD and enalapril 10 mg BID</p>	<p>DB, PG, MC, RCT</p> <p>Patients with CHF (NYHA classes II to IV), a 6 minute walk distance of 500 meters or less, and an ejection fraction &lt;40%</p>	<p>N=768</p> <p>43 weeks</p>	<p>Primary: Change in 6-minute walk distance</p> <p>Secondary: Change in NYHA functional class, QOL, ejection fraction, ventricular volumes, neurohormone levels, safety</p>	<p>Primary: There were no significant differences among the groups with regards to the 6-minute walk distance over the 43 week study period.</p> <p>Secondary: There were no significant differences among the groups with regards to the NYHA functional class or QOL at 18 or 43 weeks.</p> <p>Ejection fraction increased more with candesartan plus enalapril than monotherapy with either agent; however, the difference was not statistically significant (P value not significant). End-diastolic volumes (P&lt;0.01) and end-systolic volumes (P&lt;0.05) increased less with combination therapy than with monotherapy with either agent.</p> <p>Aldosterone decreased with combination therapy at 17 but not 43 weeks compared to candesartan or enalapril (P&lt;0.05). Brain natriuretic peptide decreased with combination therapy compared to candesartan and enalapril alone (P&lt;0.01).</p> <p>Blood pressure decreased with combination therapy compared to candesartan or enalapril alone (P&lt;0.05).</p> <p>Compared to enalapril, potassium decreased with candesartan use (P&lt;0.05) and increased with candesartan plus enalapril (P&lt;0.05). The proportion of patients with potassium levels <math>\geq 5.5</math> mmol/L was not significantly different among the treatment groups. There were no significant differences in creatinine, mortality, or hospitalizations for CHF or any cause among the three groups.</p>

				ACE inhibitors 11% (adjusted HR, 0.94; 95% CI, 0.78 to 1.13).
Packer et al. <sup>82</sup> (1999) ATLAS  Lisinopril 2.5 to 5 mg/day (low dose)  vs  lisinopril 32.5 to 35 mg/day (high dose)	DB, RCT  Patients with NYHA class II, III, or IV symptoms of heart failure associated with a LVEF $\leq$ 30% despite treatment with diuretics for $\geq$ 2 months	N=3,164  39 to 58 months	Primary: All-cause mortality  Secondary: cardiovascular mortality, hospitalizations (for any reason and for cardiovascular reasons), combinations of the primary and secondary end points	ACE inhibitors 11% (adjusted HR, 0.94; 95% CI, 0.78 to 1.13).  Primary: High-dose lisinopril was associated with a nonsignificant 8% lower risk of all-cause mortality compared to low-dose lisinopril (P=0.128).  Secondary: Cardiovascular mortality was reported in 40.2 and 37.2% of patients receiving low-dose and high-dose lisinopril, respectively (P=0.073).  High-dose lisinopril resulted in a 12% lower risk of death or hospitalizations for any reason (P=0.002), a 9% lower risk of cardiovascular mortality and hospitalization for cardiovascular reason (P=0.027) and 24% fewer hospitalizations for heart failure (P=0.002).  Dizziness and renal insufficiency were observed more frequently in the high-dose group, but the two groups were similar in the number of patients requiring discontinuation of the study medication.
AIRE Study Investigators <sup>83</sup> (1993) AIRE  Ramipril 2.5 to 5 mg BID  vs  placebo	DB, MC, PC, RCT  Patients $\geq$ 18 years of age with acute MI and clinical evidence of heart failure	N=2,006  15 months	Primary: All-cause mortality  Secondary: First event in an individual patient (death, progression to severe or resistant heart failure, reinfarction, or stroke)	ACE inhibitors 11% (adjusted HR, 0.94; 95% CI, 0.78 to 1.13).  Primary: On the intention-to-treat analysis, all-cause mortality was significantly lower for patients randomized to receive ramipril (17%) than placebo (23%). The observed risk reduction was 27% (95% CI, 11 to 40; P=0.002).  Secondary: Analysis of prespecified secondary outcomes revealed a 19% risk reduction in the ramipril group compared to placebo (95% CI, 5 to 31; P=0.008).
Wu et al. <sup>84</sup> (2021) AIRE-S (AIRE survival)  Ramipril target dose 10 mg/day	DB, MC, PC, PG, RCT  Patients $\geq$ 18 years of age with acute MI and clinical evidence of heart failure	N=603  29.6 years	Primary: All-cause mortality for UK participants  Secondary: Life expectancy and extensions of life (difference)	ACE inhibitors 11% (adjusted HR, 0.94; 95% CI, 0.78 to 1.13).  Primary: By April 9, 2019, death from all causes occurred in 266 (88.4%) patients in placebo arm and 275 (91.1%) patients in ramipril arm. Survival at the end of study follow-up was not different between the ramipril and placebo groups (HR, 0.96; 95% CI, 0.81 to 1.15) because more-or-less all patients had died at the end of follow-up.  Secondary:

Study and Drug Regimen	Study Design and Demographics	Study Size and Study Duration	End Points	Results
vs placebo			in median survival times)	Ramipril treatment improved life expectancy across all of the comorbidity groups studied, including diabetes (LED, 32.1 vs 5.0 months), previous MI (20.1 vs 4.9 months), history of heart failure (19.5 vs 4.9 months), hypertension (16.6 vs 8.3 months), angina (16.2 vs 5.0 months) and was greater for patients aged $\geq 65$ years than $< 65$ years (11.3 vs 5.7 months). The median survival time was 8.3 years (95% CI, 6.2 to 10.2 years) for placebo group and 9.6 years (95% CI, 8.3 to 10.9 years) for ramipril group. The extension of life between ramipril and placebo groups, measured by the difference in median survival time, was 14.5 (95% CI, 13.2 to 15.8) months.
Kober et al. <sup>85</sup> (1995) TRACE  Trandolapril 1 to 4 mg QD  vs  placebo  Medication was started between day 3 and 7 after the myocardial infarction.	DB, MC, PC, RCT  Men and women >18 years who were hospitalized with a recent MI and an LVEF $\leq 35\%$	N=1,749  24 to 50 months	Primary: Death from any cause  Secondary: Death from a cardiovascular cause, sudden death, progression to severe heart failure (defined as the first of the following events: hospital admission for heart failure, death due to progressive heart failure, or heart failure necessitating the administration of open-label ACE inhibition), recurrent infarction, change in the wall-motion index	Primary: During the study, 34.7% of patients in the trandolapril group died compared to 42.3% in the placebo group (P=0.001). The relative risk of death in the trandolapril group was 0.78 compared to placebo (95% CI, 0.67 to 0.91).  Secondary: Trandolapril reduced the risk of death from cardiovascular causes (RR, 0.75; 95% CI, 0.63 to 0.89; P=0.001) and sudden death (RR, 0.76; 95% CI, 0.59 to 0.98; P=0.03).  Progression to severe heart failure was less frequent in the trandolapril group (RR, 0.71; 95% CI, 0.56 to 0.89; P=0.003).  The risk of recurrent fatal or nonfatal MI was not significantly reduced (RR, 0.86; 95% CI, 0.66 to 1.13; P=0.29).  After three months, the mean change from the base-line index was 0.09 in the trandolapril group and 0.06 in the placebo group (P=0.03) but this statistically significant difference was absent at six and 12 months.

Fogari et al. <sup>93</sup> (1997)  Benazepril 10 mg QD  vs  amlodipine and benazepril 2.5-10 to 5-10 mg QD (fixed-dose combination product)	DB, MC, PC, RCT  Men and women 24 to 73 years of age (mean 55 years) with HTN inadequately controlled with ACE inhibitor monotherapy	N=448  8 weeks	Primary: Reduction in mean sitting DBP  Secondary: Reduction in sitting SBP, standing DBP and SBP, and percentage of patients with DBP <90 mm Hg (deemed excellent response) or a ≥10 mm Hg reduction (deemed good response)	Primary: Significantly greater reductions in sitting DBP were observed with benazepril 10 mg and amlodipine 2.5 mg (-5.3 mm Hg, 97.5% CI, -8.3 to -2.4; P=0.0001) and benazepril 10 mg and amlodipine 5 mg (-4.5 mm Hg, 97.5% CI, -7.4 to -1.6; P=0.0006) compared to benazepril monotherapy.  Secondary: Significantly greater reductions in sitting SBP were seen with benazepril 10 mg and amlodipine 2.5 mg (-7.9 mm Hg, 97.5% CI, -12.3 to -3.5; P=0.0001) and benazepril 10 mg and amlodipine 5 mg (-7.9 mm Hg, 97.5% CI, -12.2 to -3.6; P=0.0000) compared to benazepril monotherapy.  Significantly greater reductions in standing DBP and SBP were also reported with the combination therapy compared to benazepril monotherapy (P≤0.001).  Significantly more patients had excellent or good response with benazepril 10 mg and amlodipine 2.5 mg (69.2%; P=0.0004) and 10-5 mg (65.8%; P=0.02) compared to benazepril monotherapy (40.5%).  Tolerability was good in the three treatment groups and no significant abnormal laboratory data was detected.
Chrysant et al. <sup>94</sup> (2012)  Study 1: Benazepril 40 mg/day (Group 1)  vs  amlodipine and benazepril 5-40 mg/day, up	Post-hoc analysis of 2 trials  Patients with HTN	N=1,013  14 weeks	Primary: Change in baseline mean sitting DBP and mean sitting SBP, rate of blood pressure control (<140/90 mm Hg), rate of blood pressure control (mean sitting DBP <90 mm Hg or ≥10 mm Hg decrease	Primary: Pooled results demonstrate that combination therapy resulted in significantly greater lowering of mean sitting DBP and mean seated SBP compared to benazepril or amlodipine (P<0.001). Amlodipine and benazepril 10-20 mg/day resulted in significantly greater blood pressure reductions in White patients (mean sitting DBP: 12.99 mm Hg; mean sitting SBP: 13.72 mm Hg) compared to Black patients (8.80 and 8.72 mm Hg) (P<0.004). Amlodipine and benazepril 10-40 mg/day resulted in similar reductions in blood pressure in both White and Black patients.  The proportion of patients who achieved blood pressure control with amlodipine and benazepril 10-40 mg/day was similar between White and

<p>20 mg vs bisoprolol and HCTZ 2.5-6.25, 5-6.25, or 10-6.25 mg/day (fixed-dose combination product) vs amlodipine 2.5, 5, or 10 mg</p>	<p>moderate essential HTN, (average sitting DBP 95 to 114 mm Hg) each treatment was once daily and titrated to effect</p>		<p>measurements, adverse events, QOL questionnaire  Secondary: Not reported</p>	<p>significant for all three groups (P&lt;0.001).  SBP and DBP mean changes from baseline for the bisoprolol and HCTZ group and the amlodipine group were greater than the change from baseline for the enalapril group (P&lt;0.01).  Response rates (DBP ≤90 mm Hg or ≥10 mm Hg decrease from baseline) were 71% for the bisoprolol and HCTZ group, 69% for the amlodipine group, and 45% for the enalapril group. The response rates for the bisoprolol and HCTZ and the amlodipine groups differed significantly from the enalapril group (P&lt;0.01).  Twenty nine percent of bisoprolol patients had adverse experiences compared to 42% of amlodipine patients (P=0.12). Nearly 47% of enalapril patients had adverse experience compared to bisoprolol (P=0.04). Adverse events reported included headache, fatigue, peripheral edema, and dizziness.  Drug related adverse events were 16% for the bisoprolol and HCTZ patients, 21% for the amlodipine patients, and 23% for the enalapril patients. There was no significant difference between the groups.  Enalapril demonstrated a mean decrease from baseline of 7.9 mg/dL for TC (P=0.02 vs amlodipine) and 6.6 mg/dL for LDL-C (P=0.04 vs amlodipine) which were not significantly different from the increase from the bisoprolol and HCTZ group of 1.7 mg/dL (P=0.07 vs enalapril) for TC and +0.6 mg/dL in LDL-C. However, the increase in TGs was highest for bisoprolol and HCTZ-treated patients compared to amlodipine- and enalapril-treated patients (P=0.08, for bisoprolol and HCTZ vs enalapril).  There was not a significant difference from baseline or between treatment groups in QOL scores: 0.9 for the bisoprolol and HCTZ group, 0.5 for the amlodipine group, and 2.3 for the enalapril group.</p>

patients responded to treatment (defined by a decrease in office DBP to <90 mm Hg or ≥10 mm Hg decrease from baseline).				treatment group.  Secondary: Not reported
Strasser et al. <sup>109</sup> (2007)  Lisinopril 20 to 40 mg QD  vs  aliskiren 150 to 300 mg QD  HCTZ may be added if additional blood pressure control was required.	AC, DB, DD, MC, PG, RCT  Men and women with uncomplicated severe HTN (mean sitting DBP 105 to 119 mm Hg)	N=183  8 weeks	Primary: Safety  Secondary: Change in mean sitting DBP and SBP, percentage of responders	Primary: Both active treatments were well tolerated with an incidence of adverse events of 32.8% for aliskiren and 29.3% for lisinopril. The proportion of patients discontinuing treatment due to adverse events was 3.2% for aliskiren and 3.4% for lisinopril. The most frequently reported adverse events in both groups were headache, nasopharyngitis and dizziness.  Secondary: Aliskiren showed similar reductions from baseline to lisinopril in mean sitting DBP (-18.5 vs -20.1 mm Hg) and SBP (-20.0 and -22.3 mm Hg).  Responder rates were 81.5% with aliskiren and 87.9% with lisinopril. Approximately half of patients required the addition of HCTZ to achieve blood pressure control (53.6% for aliskiren and 44.8% for lisinopril).
Rosei et al. <sup>110</sup> (2003)  Lisinopril 20 mg QD  vs  nebivolol 5 mg QD	DB, MC, PG, RCT  Patients between 24 and 65 years with mild to moderate uncomplicated essential HTN that was newly diagnosed, or previous antihypertensive therapy was withdrawn at >1	N=65  12 weeks	Primary: Response rates, changes in sitting blood pressure  Secondary: Standing blood pressure, sitting and standing heart rate	Primary: There was not a significant difference in response rates observed between the two treatment groups.  Both treatment groups significantly reduced sitting SBP (P<0.0001) and DBP (P<0.0001) throughout the study compared to baseline but there were no significant differences observed between the treatment groups at most visits, but at week eight, DBP was significantly lower in the nebivolol group compared to the lisinopril group (P<0.05).  Secondary: There was not a significant difference observed between treatment groups in standing blood pressure measurements.

<p>O'Brien et al.<sup>120</sup> (2007)</p> <p>Aliskiren 150 mg QD for 3 weeks, then HCTZ 25 mg QD was added for an additional 3 weeks (if ABPM remained <math>\geq 135/85</math> mm Hg)</p> <p>vs</p> <p>irbesartan 150 mg QD for 3 weeks, then aliskiren 75 mg QD added for 3 weeks, then aliskiren 150 mg QD added for 3 weeks</p> <p>vs</p> <p>ramipril 5 mg QD for 3 weeks, then aliskiren 75 mg QD added for 3 weeks, then aliskiren 150 mg QD added for 3 weeks</p>	<p>3 OL studies</p> <p>Men and women 18 to 80 years with ambulatory SBP <math>\geq 140</math> and <math>\leq 180</math> mm Hg without treatment</p>	<p>N=67</p> <p>6 to 9 weeks</p>	<p>Primary: Change in daytime systolic ABPM with combination therapy compared with monotherapy</p> <p>Secondary: Change in daytime diastolic ABPM, nighttime systolic and diastolic ABPM, daytime and nighttime heart rates, plasma renin activity</p>	<p>Primary: Aliskiren coadministered with HCTZ (P=0.0007) or ramipril (P=0.03) led to significantly greater reductions in daytime systolic ABPM compared to monotherapy. There was a trend for a reduction in daytime systolic ABPM with the addition of aliskiren to irbesartan; however, this trend was not statistically significant.</p> <p>Secondary: Aliskiren plus HCTZ significantly lowered daytime diastolic ABPM compared to aliskiren monotherapy (P=0.0006). Changes in nighttime systolic and diastolic ABPM followed similar trends but did not achieve statistical significance (P=0.06 and P=0.09, respectively). No changes in heart rate were observed with either aliskiren regimen.</p> <p>Aliskiren added to irbesartan did not significantly change diastolic ABPM compared to irbesartan monotherapy; however, nighttime systolic and diastolic ABPM were significantly reduced (P&lt;0.05 for all). No changes in heart rate were observed with either irbesartan regimen.</p> <p>Mean diastolic ABPM was significantly decreased with the addition of aliskiren 150 mg (P&lt;0.05) but not aliskiren 75 mg to ramipril monotherapy. Both aliskiren doses significantly decreased nighttime systolic and diastolic ABPM (P&lt;0.05 for all). No changes in heart rate were observed with either ramipril regimen.</p> <p>Aliskiren alone significantly inhibited plasma renin activity by 65% (P&lt;0.0001), while ramipril and irbesartan monotherapy increased renin activity by 90 and 175%, respectively. When aliskiren was coadministered with HCTZ, ramipril or irbesartan, plasma renin activity remained similar to baseline levels or decreased.</p>

weeks				
Tytus et al. <sup>121</sup> (2007)  Trandolapril 1 to 4 mg/day  At 14 weeks after treatment initiation, subjects not achieving blood pressure targets could receive a combination of trandolapril 4 mg/day plus verapamil 240 mg/day with or without a diuretic.	MC, OL, PRO  Patients with stage 1 or 2 HTN who were treatment naïve (82%) or uncontrolled on a diuretic (11%) or calcium-channel blocker (7%); uncontrolled HTN was defined as $\geq 140/90$ mm Hg in subjects with no other risk factors or $\geq 130/80$ mm Hg in subjects with diabetes or kidney disease	N=1,683  26 weeks	Primary: Percentage of patients reaching target blood pressure at 14 weeks  Secondary: Percentages of subjects with stage 1 and 2 HTN who achieved target blood pressure, percentages of subjects who achieved a drop in SBP of $\geq 20$ mm Hg and/or DBP $\geq 10$ mm Hg, absolute changes in SBP and DBP, adverse events	Primary: At 14 weeks of treatment, 71.2% of patients who were treated with trandolapril monotherapy reached SBP/DBP $< 140/90$ mm Hg.  Secondary: At 26 weeks, 73.4% of patients achieved a target level of SBP/DBP $< 140/90$ mm Hg. Of the 683 subjects with stage 2 HTN, 64.6% achieved the target level after 14 weeks of trandolapril and 67.9% after 26 weeks.  At 14 weeks, 78.8% of subjects treated with a trandolapril regimen experienced a decrease in SBP of $\geq 20$ mm Hg or a decrease in DBP of $\geq 10$ mm Hg.  Statistically significant ( $P < 0.001$ ) and clinically relevant mean decreases in SBP of -16.1 mm Hg and in DBP of -8.8 mm Hg were observed from four weeks of treatment onward for the overall study population. The mean reductions in SBP and DBP were -21.5 and -11.9 mm Hg, respectively at 14 weeks ( $P < 0.001$ ), and -22.4 and -12.7 mm Hg, respectively, at 26 weeks ( $P < 0.001$ ).  A total of 343 predominantly mild, nonserious adverse events were attributed to the study drugs, reported by 15.3% of the 1,650 subjects. The most frequently reported nonserious adverse events were cough (6.3%); gastrointestinal disorders (2.3%), predominantly nausea; and headache (2.1%). No serious adverse events were attributed to the study treatment.
Tytus et al. <sup>122</sup> (2011) MAVIKtory  Trandolapril 1 to 2 mg/day  With or without existing antihypertensive therapy.	MC, OS  Patients with HTN	N=8,787  6 months	Primary: Proportion of patients reaching blood pressure targets, safety  Secondary: Not reported	Primary: The target of $< 140/90$ mm Hg was achieved by 67.3% of patients. The lower mean target of 133.4/83.3 mm Hg for nondiabetic patients and 128.6/79.3 mm Hg for diabetic patients were achieved by 52.2%. Mean reductions from baseline to trial end were 19.4 mm Hg (95% CI, -19.9 to -19.0) in SBP and 10.1 mm Hg (95% CI, -10.4 to -9.8) in DBP.  Cough was the most commonly reported adverse event (4.2%).  Secondary: Not reported

<p>HCTZ 40-12.5 to 40-25 mg/day, followed by forced titration after 1 month on benazepril and HCTZ 20-12.5 mg (fixed-dose combination product)</p>				<p>HCTZ group (P&lt;0.0001).</p>
<p>Hou et al.<sup>134</sup> (2007) ROAD</p> <p>Benazepril 10 mg/day vs individual up-titration (10 to 40 mg/day with median dose of 20 mg/day)</p> <p>or</p> <p>losartan 50 mg/day vs individual up-titration (50 to 200 mg/day with median dose of 100 mg/day)</p> <p>Up-titration was performed to optimal antiproteinuric and tolerated</p>	<p>OL, PRO, RCT</p> <p>Patients aged 18 to 70 years with proteinuria and chronic renal insufficiency who did not have diabetes</p>	<p>N=360</p> <p>3.7 years (median follow-up)</p>	<p>Primary: Time to composite of doubling of serum creatinine, ESRD or death</p> <p>Secondary: Changes in level of proteinuria, rate of progression of renal disease</p>	<p>Primary: Compared to the conventional dosages, optimal antiproteinuric dosages of benazepril and losartan that were achieved through up-titration were associated with a 51 and 53% reduction in the risk for the primary end point (P=0.028 and P=0.022, respectively).</p> <p>There was no statistically significant difference between benazepril and losartan in the overall relative risk reduction at their respective optimal antiproteinuric dosages or at conventional dosages.</p> <p>Secondary: Optimal antiproteinuric dosages of benazepril and losartan at comparable blood pressure control, achieved a greater reduction in both proteinuria and the rate of decline in renal function compared to their conventional dosages.</p> <p>There was no significant difference in proteinuria reduction between benazepril and losartan at both conventional and optimal antiproteinuric dosages. Changes in renal function were similar between benazepril and losartan arms at both conventional and optimal antiproteinuric doses (P&gt;0.05).</p> <p>There was no significant difference for the overall incidence of major adverse events between groups that were given conventional and optimal dosages in any of the treatment arms.</p>
